
Hydraulic Mining, Devil's Creek, Reefton, New Zealand.

Of the metals and minerals with which gold is found intimately associated in nature are the following: antimony, arsenic, bismuth, cobalt, copper, iridium, iron, lead, manganese, nickel, osmium, palladium, platinum, selenium, silver, tellurium, tungsten, vanadium, and zinc, often as an alloy in the case of palladium, platinum, selenium, silver (always), and tellurium. The methods of separation vary with the nature of the ore and the conditions of the locality. In the case of sulphides of some of the base metals the sulphur can be oxidised by burning in suitable kilns, so as to afford sulphurous or sulphuric acid, leaving the gold and other metals in the 'cinders,' whence they can be recovered by solution. Where the base metal is volatile it may be obtained by condensing the fumes. To get rid of the sulphur and arsenic in the ore (with or without

utilising them) is generally the first step, and is most commonly performed in some kind of furnace. This done, the 'sweet' cinders are subjected to the action of chlorine, which forms a soluble chloride with the gold, easily separable by washing with water. There are many ways of effecting this, some being the subjects of patent rights, for which very large sums have been injudiciously paid by the British public. Sometimes the washing and chlorination are combined in one operation by placing salt in the furnace; but in many cases this has led to enormous loss of gold by volatilisation. This question is too complicated for discussion here, but may be studied in Lock's *Practical Gold Mining* (1889), which contains also a complete bibliography of the subject.

The most important physical and chemical properties of gold are as follow: In malleability it stands first of the metals, and its ductility is remarkable, hence it may be beaten into leaves not exceeding $\frac{1}{282000}$ of an inch thick, and quite translucent, and 1 grain in weight may be made to cover 56 square inches of surface, or drawn into a wire 500 feet long. Its specific gravity is about 19·2 when fused, or 19·4 when hammered, being less than platinum and iridium. Its colour and lustre in the concrete form are sufficiently familiar, but when thrown down from solution in a minute state of division it appears brown, and seen by transmitted light while held in suspension the atoms exhibit a purple tint, as also when it is volatilised. In softness it approaches lead, and in tenacity it ranks below iron, platinum, copper, and silver; yet a wire only $\frac{1}{8\,8\,8\,0}$ of an inch thick will support 150 lb. It is an excellent conductor of heat and electricity. Its fusing-point is 2016° by Daniell's pyrometer. When pure it is difficult of volatilisation, requiring the intense heat of an oxy-hydrogen flame, or a strong electric current. It was long thought to be practically non-volatile in the heat of an ordinary furnace; but, as has been already stated, under certain conditions it is very readily vaporised, and immense losses have been incurred in consequence.

Having but little affinity for oxygen, gold is not affected by exposure to the air; but two oxides may be formed artificially—the protoxide, AuO, by decomposing gold protochloride with a potassic solution, and a teroxide, AuO_3, or auric acid by boiling terchloride with magnesia or carbonate of soda. Silica, on the other hand, attacks it with avidity, forming a silicate which is extremely insoluble in water, but decomposes with age. Sulphuretted hydrogen combines with gold at ordinary temperatures to form a sulphide, which is soluble in alkaline sulphides, and slightly so in pure water. A bisulphide is obtained by passing sulphuretted hydrogen through a cold solution of terchloride; and a double sulphide of gold and potash is produced by heating gold in a very fine state with sulphur and carbonate of potash, constituting the porcelain gilding known as 'Burgos lustre.' Gold is affected by selenic acid, and is dissolved by iodine and by hyposulphite of soda. It is not affected by alkalies, nor by hydrochloric, nitric, or sulphuric acid alone; but is rapidly dissolved by aqua regia (nitro-hydrochloric acid), and by any substance liberating chlorine. Two chlorides are known: a proto salt, AuCl, and a ter salt, $AuCl_3$, the latter forming reddish-yellow solutions with water, ether, and alcohol. Gold is volatile in the presence of chlorine at all temperatures between boiling water and white heat, and cannot be recovered by condensation, but only by decomposition of the volatile chloride. Gold chloride and sulphide remain in solution in presence of excess of sulphuretted hydrogen and an alkaline carbonate, the gold gradually depositing as the carbonic acid escapes. Gold solutions are precipitated by oxalic, tartaric, citric, and other organic acids; also by wood, bark, charcoal, and other organic matters, the gold being thrown down in a pulverulent form, and recoverable by burning. Gold is also precipitated by iron sulphate, and by sulphur dioxide in the presence of water, as a metallic powder; further, by copper sulphide, which, when converted into sulphate, yields the gold in a metallic state highly favourable for collecting. Mineral sulphides (e.g. pyrites) decompose gold solutions, and collect the gold in a coherent form; they similarly attack gold chloride volatilised in the roasting furnace, and absorb it.

Gold forms many alloys with other metals. Those occurring in nature have been already mentioned; their importance is very small industrially. But another alloy, that with copper, is of prominent value, being the basis of gold coinages. The admixture of copper lessens the density, but increases the hardness and fusibility of the alloy, rendering it better suited to the purpose. The proportion of copper in standard gold coin varies, being 8·33 per cent. in Great Britain, and 10 per cent. in France and the United States. In Great Britain, since 1816, gold is the only legal tender for sums above forty shillings; in many other countries gold coin is latterly coming into extended use where formerly silver only was employed. The market price of gold bullion varies with its purity: pure gold (24 carat) is worth £4, 4s. 11½d. per oz., while 22 carat fetches only £3, 17s. 10½d., and 20 carat £3, 10s. 9½d. (see BIMETALLISM, CURRENCY, MONEY). The readiness with which gold alloys with mercury is very largely utilised in collecting the scattered fragments of the precious metal, in treating auriferous sands and rocks, and, on a smaller scale, in gilding. The conditions governing perfect amalgamation of crude gold demand most minute attention from the miner. The fanciful alloys of gold made by jewellers are chiefly:

Red gold	75	parts	fine	gold	+	25	parts copper
Dead leaf gold	70	"	"	"	+	30	" silver.
Green gold	75	"	"	"	+	25	" "
Water green gold	60	"	"	"	+	40	" "
Blue gold	75	"	"	"	+	25	" iron.

See ALLOYS, AMALGAM; also ASSAY, METALLURGY, MINING. Gold may and often does cost more to produce than it is worth. In Victoria, where it is economically worked, the total average of gold produced per head of all engaged in gold-mining was in 1887 only £96, 17s. 2d.; so that the gold miner's wage may safely be set down as lower than those given in the colony for many other kinds of work. Among notable gold discoveries are those in California in 1848; Australia (New South Wales and Victoria) in 1851; British Columbia, 1858; New Zealand and Nova Scotia in 1861; South Africa (Transvaal) and Sutherlandshire, 1868; Western Australia, 1870; South Australia, 1886; Klondyke, 1896. The enormous output of the Transvaal (q.v.) and Western Australia (q.v.) led, in 1895–96, to wild speculation.

Fulminating gold is an extremely explosive green powder made from teroxide of gold and caustic ammonia.—*Purple of Cassius* is a compound of gold and tin used in colouring Glass (q.v.).—*Mosaic gold* is sulphide of Tin (q.v.).

See, besides the writer's work above mentioned, T. K. Rose, *The Metallurgy of Gold* (1894); H. Louis, *Handbook of Gold Mining* (1894); and works by T. S. G. Kirkpatrick (1890), and Macdermott and Duffield (1890).

Gold, FIELD OF THE CLOTH OF, the meeting in 1520 between Henry VIII. (q.v.) and Francis I.

Goldau, a small Swiss town behind the Rigi and on the St Gotthard railway, was utterly destroyed by a landslip, 2d September 1806; while the

neighbouring villages of Businger, Röthen, and Lowerz were overwhelmed, and a part of the Lake of Lowerz was filled up, by the fall of the upper slope of Mount Rossberg. The valley is now a wild rocky waste, overgrown with grass and moss. The village of Neu-Goldau, on the line of the Rigi railway, consists of but a few houses.

Gold-beater's Skin, a very thin but tough membrane prepared from the external coat of the cæcum a part of the great intestine—of the ox. It is drawn off in lengths of 25 inches or more from the other coats, immersed in a weak solution of potash, and scraped with a blunt knife upon a board. After a soaking in water, two of these pieces are stretched upon a frame, dried, and then separated by a knife. Each strip is again fixed with glue to a frame, and washed over with a solution of alum. When dry it is next coated with fish-glue, and afterwards with white of egg. The piece of membrane is then cut into squares of 5 or 5½ inches. A gold-beater's *mould* contains from 900 to 950 of these squares, and to furnish this nearly 400 oxen are required. Besides its application in gold-beating, this fine membrane is used in the dressing of slight wounds.

Gold-beating is a very ancient art, having been practised from a remote period among oriental nations. Gilding with leaf-gold is found on the coffins of Egyptian mummies, on some Greek pottery vases of as early a date as the 4th or 5th century B.C., and on portions of the palaces of ancient Rome. Beckmann states that the German monk Theophilus, who appears to have lived at least as early as the 12th century, describes the process nearly as it is at present, the gold having been beaten between parchment, which is practically the same as the modern method. Formerly the gold-beater's art was largely practised in Florence, but in that city the production of fine gold-leaf has greatly diminished during the latter half of the 19th century through French and German competition, the latter country especially now making large quantities of an inferior gold-leaf. Gold-beating is practised in most of the large towns of the United Kingdom, but London is its chief centre.

According to the shade of colour required gold is alloyed for beating either with silver or copper or with both. The proportion of copper rarely exceeds one-twentieth part that of the gold, but the quantity of silver in the alloy is sometimes much larger. The ingot being prepared, it is rolled out into a ribbon 1½ inches wide, a 10-feet length of which weighs an ounce. This length of ribbon is then annealed and cut into about 75 pieces of equal weight. Formerly these were placed between leaves of vellum, but a tough kind of paper is now used with a leaf of vellum at intervals through the packet, which is from 3½ to 4 inches square. The pile of bits of gold ribbon thus interleaved is called a 'cutch,' and this, having been placed upon a thick block of marble about 9 inches square, resting on a strong bench, is beaten with a hammer weighing from 15 to 17 lb., till the pieces of gold extend to the size of the squares of the paper. The hammer rebounds by the elasticity of the vellum, which saves or at least lessens the labour of lifting it. Each square of gold in the cutch is now taken out, cut into four pieces, and placed between leaves of Gold-beater's Skin (q.v.). This packet, termed a 'shoder,' is beaten with a 9-lb. hammer for about two hours, or six times as long as in the first or cutch beating. For the final beating the gold leaves from the shoder are again divided into four, and each piece placed between leaves of fine gold-beater's skin, about 950 of which form a packet termed a 'mould.' After four hours' beating with a 7-lb. hammer the gold-leaf in the mould is of the thickness usually sold, which averages the 282,000th part of an inch. Each skin of the mould is rubbed over with calcined gypsum to prevent the gold adhering to it. One grain of gold in the form of gold-leaf of the ordinary thickness used in gilding measures about 56 square inches, but it can be beaten out to the extent of 75 square inches. A grain of silver can be beaten out to a still greater extent, but the leaf would really be thicker, since this metal has not nearly the density of gold.

An alloy consisting of 37 grains of gold, 2 of silver, and 1 of copper makes a leaf with a deep yellow colour. A compound containing 4 grains of gold to 1 of silver gives a pale-yellow leaf, but as the proportion of silver is lessened it becomes deeper in the yellow. Seen by transmitted light gold-leaf when only slightly alloyed appears green, but if it contains a large proportion of silver its colour is violet. For external gilding, leaf made from pure gold is the best, as it does not tarnish by atmospheric influences; but it is not so convenient for ordinary purposes.

Goldberg, a town of Prussian Silesia, on the Katzbach, 13 miles by rail WSW. of Liegnitz. It owes both origin and name to its former rich gold-mines; suffered much from Mongols and Hussites, the Thirty Years' War, the campaign of 1813, and finally from great fires (1863–74); and now has manufactures of cloth, flannel, &c. Pop. 6436.

Gold Coast, a British crown colony on the Gulf of Guinea, with an area of 15,000 square miles, or including protectorates, 46,600 square miles, and a population of 1,475,000 (of whom only 150 are Europeans). It extends from 5° W. to 2° E. long., between the Slave Coast and the Ivory Coast, has a coast-line of some 350 miles, and reaches inland to Ashanti (beyond the Prah), in which (at Kumasi) there is, since 1895, a British resident. Its shores are low and swampy, and very difficult of approach owing to the heavy surf. From the lagoons of the coast the country rises gradually towards the interior, and is furrowed by numerous small streams. The principal exports are palm kernels and oil, india-rubber, gold-dust, ivory, and monkey skins; but cocoa-nuts, copra, coffee, Calabar beans, corn, ground-nuts, Guinea grains, ginger, cam-wood, gum copal, tobacco, and porcupine quills are also produced. The climate on the coast is very unhealthy, but is better inland. The negro inhabitants are largely under the management of their own chiefs. The exports and imports have each an annual value of £600,000 or £700,000. The chief towns are Accra, Elmina, and Cape Coast Castle. The whole of the district geographically known as Gold Coast is British, except the French settlements of Grand Bassam, Assinie, Grand Lahou, and Jackeville. German Togoland is on the Slave Coast. See Ellis, *History of the Gold Coast* (1893), and Lucas, *Historical Geography of the British Colonies*, Vol. III. (1895).

Golden Age. See AGE.

Golden Beetle, the name popularly given to many members of a genus of coleopterous insects, Chrysomela, and of a sub-family, Chrysomelinæ, belonging to the tetramerous section of the order. The body is generally short and convex, the antennæ are simple and wide apart at the base; some of the species are destitute of wings. None are of large size, but many are distinguished by their metallic splendour of colour. The finest species are tropical, but some are found in Britain—e.g. the golden *C. cerealis* with purple stripes found on Snowdon, and the brassy-green *C. polita* and *C. staphylea* commonly found on nettles in spring. In north temperate countries some of the adults of the autumnal brood sleep through the winter, awakening in spring to reproductive functions. Some of

them, in the larval state, commit ravages on the produce of the field and garden.

Golden Bull (Lat. *bulla aurea*), so called from the gold case in which the seal attached to it was enclosed, was an edict issued by the Emperor Charles IV. in 1356, mainly for the purpose of settling the law of imperial elections. See GERMANY, ELECTORS, BULL.

Golden-crested Wren (*Regulus cristatus*), a very beautiful bird of the family Sylviidæ, the smallest of British birds. Its entire length is scarcely three inches and a half. Notwithstanding its English name, it is not really a wren, but this name continues in popular use rather than Regulus and Kinglet, which have been proposed instead. The golden-crested wren is greenish-yellow on the upper parts, the cheeks and throat grayish-white; the crown feathers elongated, and forming a bright yellow crest. In its habits it is intermediate between the warblers and the tits.

Golden-crested Wren (*Regulus cristatus*).

It particularly affects fir-woods. It is not uncommon in Britain, from the most southern to the most northern parts; but many come also from more northern countries to spend the winter, and it is on record that, in October 1822, thousands were driven on the coast of Northumberland and Durham by a severe gale from the north east. The nest of this bird is suspended from the outermost twigs of a branch of fir, some of them being interwoven with it.—Another species (*R. ignicapillus*), with more vividly red crest, is sometimes found in Britain, and species are found in Asia and North America.

Golden-eye Fly (*Chrysopa perla*), also called Lacewing Fly, a neuropterous insect, common in Britain; pale green, with long thread-like antennæ, long gauze-like wings, and brilliant golden eyes.

Golden-eye Fly (*Chrysopa perla*):
a, cocoon; *b*, the same magnified; *c*, larva; *d*, the same magnified, and freed from adhering substances; *e*, perfect insect, on a branch to which its eggs are attached.

Its flight is feeble. The length, from the tip of the antennæ to the tip of the wings, is almost an inch and a half, but the insect without wings and antennæ is not more than one-third of this. The female attaches her eggs, in groups of 12 or 16, by long hair-like stalks, to leaves or twigs, where they have been mistaken for fungi. The larvæ are ferocious-looking little animals, rough with long hairs, to which particles of lichen or bark become attached; they are called *aphis-lions*, and are very useful in the destruction of aphides, on which they feed. The pupa is enclosed in a white silken cocoon, from which the fly is liberated by a lid. The general facts above stated are also true of another very common species (*Ch. vulgaris*) a delicate green insect, with a body about half an inch long. The species of Chrysopa emit a very disagreeable odour. The nearly allied genus Hemerobius is also abundantly represented in Britain and elsewhere.

Golden Fleece (Fr. *toison d'or*), in Greek tradition, the fleece of the ram Chrysomallus, the recovery of which was the object of the famous expedition of the Argonauts (q.v.). The Golden Fleece has given its name to a celebrated order of knighthood in Austria and Spain, founded by Philip III., Duke of Burgundy and the Netherlands, at Bruges on the 10th January 1429, on the occasion of his marriage with Isabella, daughter of King John I. of Portugal. This order was instituted for the protection of the church, and the fleece was probably assumed for its emblem as much from being the material of the staple manufacture of the Low Countries as from its connection with heroic times. The number of the knights was thirty-one, and they themselves filled up vacancies by vote. This continued till 1559, when Philip II. of Spain held the last (the 23d) chapter of the order in the cathedral of Ghent; and subsequently Philip obtained from Gregory XIII. permission to nominate the knights himself. After the death of the last Hapsburg king of Spain in 1700, the Emperor Charles VI. laid claim to the sole headship of the order in virtue of his possession of the Netherlands, and, taking with him the archives of the order, celebrated its inauguration with great magnificence at Vienna in 1713. Philip V. of Spain contested the claim of Charles; and the dispute, several times renewed, was at last tacitly adjusted by the introduction of the order in both countries. The insignia are a golden fleece (a sheepskin with the head and feet attached) hanging from a gold and blue enamelled flint-stone emitting flames, and borne in its turn by a ray of fire. On the enamelled obverse is inscribed *Pretium laborum non vile*. The decoration was originally suspended from a chain of alternate flints and rays, for which Charles V. allowed a red ribbon to be substituted, and the chain is now worn only by the Grand master. The Spanish decoration differs slightly from the Austrian. The costume consists of a long robe of deep red velvet, lined with white taffetas, and a long mantle of purple velvet lined with white satin, and richly trimmed with embroidery containing fire-stones and steels emitting flames and sparks. On the hem, which is of white satin, is embroidered in gold, *Je l'ay empris*. There is also a cap of purple velvet embroidered in gold, with a hood, and the shoes and stockings are red. See Reiffenberg, *Histoire de l'Ordre de Toison d'Or* (1830); and Zoller, *Der Orden vom Goldenen Vlies* (1879).

Order of the Golden Fleece.

Golden Gate, a channel 2 miles wide, forming the entrance to the magnificent Bay of San Francisco, and washing the northern shore of the peninsula on which San Francisco is built. It is defended by Fort Point, at the north-western extremity of the peninsula, and by a fort on Alcatraz Island, inside the entrance.

Golden Horde. See KIPTCHAK.

Golden Horn. See CONSTANTINOPLE.

Golden Legend (Lat. *Aurea Legenda*), a celebrated medieval collection of lives of the greater saints, which passed through more than a hundred editions, and was rendered from Latin into most of the western languages. It is the work of Jacobus de Voragine (1230–98), a Dominican, who was Archbishop of Genoa for his last six years, and wrote many works, among them the *Chronicon Januense*, a history of Genoa from mythical down to contemporary times. The Golden Legend has 182 chapters, and is divided into five sections, corresponding to as many divisions of the year. It contains many puerile legends and contemporary miracles vouchsafed especially to Dominicans. A translation was made by William Caxton, and published in 1483. A good edition is that by Grasse (Dresden, 1846).

Golden Number for any year is the number of that year in the Metonic Cycle (q.v.); and, as this cycle embraces nineteen years, the golden numbers range from one to nineteen. The cycle of the Greek astronomer Meton (432 B.C.) came into general use soon after its discovery, and the number of each year in the Metonic cycle was marked in golden colours in the Roman and Alexandrian calendars. Hence the origin of the name. Since the introduction of the Gregorian calendar the point from which the golden numbers are reckoned is 1 B.C., as in that year the new moon fell on the 1st of January; and, as by Meton's law the new moon falls on the same day (1st of January) every nineteenth year from that time, we obtain the following rule for finding the golden number for any particular year. '*Add one to the number of years, and divide by nineteen: the quotient gives the number of cycles and the remainder gives the golden number for that year; and if there be no remainder, then nineteen is the golden number, and that year is the last of the cycle.*' The golden number is used for determining the Epact (q.v.) and the time for holding Easter (q.v.).

Common Golden-rod (a garden variety).

Golden Oriole. See ORIOLE.

Golden-rod (*Solidago*), a genus of Compositæ, closely allied to Aster. Only the common *S. Virgaurea* is British, a few others are European, but most (more than 100) belong to North America, where their bright colouring lightens up the beautiful autumnal scenery. Some—e.g. *S. canadensis*, *grandiflora*, &c.—are found in old-fashioned borders, but are so coarse and weedy as hardly to merit a place beyond the shady corner of the roughest shrubbery. *S. Virgaurea* had at one time a great reputation as a vulnerary, whence probably the name (from Lat. *solidare*, 'to unite'). The leaves of this and a fragrant North American species, *S. odora*, have been used as a substitute for tea. They are mildly astringent and tonic.

Golden Rose, a rose formed of wrought gold, and blessed with much solemnity by the pope in person on the fourth Sunday in Lent, which is called, from the first word in the service for the festival, 'Lætare Sunday.' The rose is anointed with balsam, fumigated with incense, sprinkled with musk, and is then left upon the altar until the conclusion of the mass. It is usually presented to some Catholic prince, whom the pope desires especially to honour, with an appropriate form of words. The practice seems to have originated in the 13th century. Amongst recipients have been Henry VIII. (three times), Queen Mary of England, Maria Theresa, Napoleon III., and Isabella II. of Spain.

Gold-eye, or MOON-EYE (*Hyodon tergisus*), a peculiar fish, abundant in the western rivers and lakes of North America. It has many technically interesting peculiarities of structure, and forms a family by itself in the Physostomi order of bony fishes. It measures about a foot in length.

Goldfinch (*Carduelis elegans*), the most beautiful of British finches (Fringillidæ). It is about five inches in length; has a thick, conical, sharp-pointed bill; and is noteworthy among British birds for its handsome plumage, in which black, crimson-red, yellow, and white are, in the adult male, exquisitely mingled. The female has less crimson on the throat and no yellow on the breast, and the 'gray-pate' or 'bald-pate' young are also of course much less gaily adorned than the full-grown males.

Goldfinch (*Carduelis elegans*).

Goldfinches occur in small flocks on open uncultivated ground, feeding on thistles and other composites, or are found breeding in gardens and orchards. The nest, usually in a fruit-tree, is even neater than that of the chaffinch, lined with the finest down, but without lichens; the eggs (4 or 5) are grayish-white, with purplish-brown streaks and spots; there are two broods in the year; the young are fed on insects. The goldfinch is still a common summer bird in Britain, especially in the south; most migrate southwards in October. It breeds throughout Europe, especially in the south, and ranges from the Canaries, through North Africa, to Persia. Its soft pleasing song, intelligence, docility, liveliness, and lovingness make it, to its cost, a favourite cage-bird. See Howard Saunders, *Manual of British Birds*.

Goldfish, or GOLDEN CARP (*Carassius auratus*), a Chinese and Japanese fresh water fish nearly allied to the carp (*Cyprinus*), but lacking barbels. In its warm native waters it is brownish, like its neighbour species, the Crucian Carp (*C. carassius*), while in its more familiar domesticated state it loses the black and brown pigment, becomes golden yellow, or passes more completely into albinism in those unpigmented forms known as silver fish. Young specimens are dark in colour, the loss of pigment and the consequent golden tint becoming marked as they grow older. It seems to have been introduced into England in 1691, and is often kept in aquaria, or with more success in ponds, especially in such as are warmed by an inflow of hot water from engines. In temperatures of 80° F. or more it thrives well and breeds abundantly. The goldfish is naturalised in some continental rivers, and has had a wide artificial distribution throughout the world. In aquaria the fish are best fed on worms, insects, and the like, and care must be taken that the water is kept fresh. Monstrosities such as double or multiple tails or much modified fins frequently occur in artificial conditions. Of these the most remarkable is the 'telescope fish.' There are large breeding-establishments in southern and western France, in various parts of Prussia, and at Palz in Styria the latter furnishing 100,000 goldfish in a year. See Mulertt, *The Goldfish and its Systematic Culture* (1884).

Gold Hill, a settlement in Nevada, now part of Virginia City (q.v.), which, on Mount Davidson, is the famous Comstock Lode (q.v.).

Goldilocks is a common name for the *Ranunculus auricomus*. See RANUNCULUS.

Gold Lace. This term is applied in a general way to more than one kind of fabric made of thread covered with gilt silver wire. The 'gold wire' used in the manufacture of gold thread is nearly always in India, where a great deal is made, composed of pure silver with a thin coating of gold. But in European countries it is only the very best qualities of this wire which are made of unalloyed silver. A good quality of English gold thread is made from wire consisting of one part of copper added to twenty-five of silver, which is afterwards coated with gold. But alloys of copper and silver in many proportions are used, some wire containing only one part of silver to sixty of copper. The silver, or alloy of copper and silver, is made into a rod 1½ inch in diameter, and then annealed and polished to prepare it for its coating of gold. This is laid on in the form of leaves of pure gold, and subjected, for the best qualities of wire, to the fire-gilding process—i.e. the gold-coated rod is heated to redness on burning charcoal, which causes the leaf to adhere firmly. Rods so treated are next smeared with wax, and drawn through the holes of a steel drawplate (see WIRE, in Vol. X.). The wire is frequently annealed during the process of drawing, and this requires to be very skilfully done, or the golden tint of the surface is lost. Gold wire for thread is generally drawn down to a size measuring 1100 to 1400 yards to the ounce of metal. Finer sizes reach the length of 1800 to 2000 yards to the ounce, and to attain this fineness the wire is drawn through perforated gems, such as diamonds or rubies. The fine wire, after being annealed, is flattened between polished steel rollers. Finally the flat wire, or rather ribbon, is wound over yellow or orange coloured silk, so as completely to envelop it, by a spinning engine. The gold thread is then finished. Some of the best qualities of the metal covering or 'plate' of this thread have 12 dwt. of gold to the pound of silver or of alloy. Inferior kinds have as little as 2 dwt. to the pound, and still cheaper sorts of thread are covered with flattened copper wire which has received a thin coating of electro-deposited silver, and this afterwards receives, on the outside of the thread only, a still thinner electro-deposited coating of gold—two grains of the precious metal covering 3000 square inches of surface. For this very cheap kind of thread yellow cotton is used instead of silk.

The only difference between gold and silver thread is that the thin coating of gold is wanting on the latter. Gold thread is used in the manufacture of military lace, which is made in several patterns for officers of different ranks and for various divisions of the army and navy. This, however, is a woven substance and not true lace; but some real lace is made both of gold and silver thread. Both kinds of thread are also used for facings of liveries, and for ecclesiastical robes, altar cloths, and banners. These and other fabrics are either embroidered or woven, but often only in part, with the thread (see BROCADE, DAMASK, and EMBROIDERY). Much of the 'gold thread' used for theatrical dresses and decorations has only a covering of Dutch Metal (q.v.), and the 'silver thread' in these is spun with a covering of a cheap white alloy, having a mere film of silver on the surface.

Gold Leaf. See GOLD BEATING.

Gold of Pleasure (*Camelina*), a small genus of Cruciferæ. The common Gold of Pleasure (*C. sativa*; Fr. *Cameline*, Ger. *Dotter*) is an annual plant of humble appearance, but with abundant yellow flowers. It is most commonly known as a weed in lint-fields, although it is also cultivated alone or mixed with rapeseed in parts of Germany, Belgium, and the south of Europe for the sake of the abundant oil contained in its seeds. Its seeds and oil-cake are, however, inferior to those of lint, and its oil is apt to become rancid and is less valued than that of rape or colza. The value of the plant in agriculture depends much on its adaptation to poor sandy soils, and on the briefness of its period of vegetation, adapting it for being sown after another crop has failed, or for being ploughed down as a green manure. The crop is cut or pulled when the pouches begin to turn yellow; but the readiness with which seed is scattered in the field, rendering the plant a weed for future years, is an objection to its cultivation. The stems are tough, fibrous, and durable, and are used for thatching and for making brooms; their fibre is sometimes even separated like that of flax, and made into very coarse cloth and packing-paper. The seeds are used for emollient poultices. *C. dentata* is of similar habit and properties, but is not cultivated.

Goldoni, CARLO, the creator of the modern Italian comedy of character and domestic life, was born in 1707 at Venice. Although he went through a course of law studies there and at Pavia, his heart was set even from a child upon plays and playwriting. His first serious attempts were tragedies, one of which, *Belisario*, was successful at Venice in 1732. But he soon discovered that his forte was comedy rather than tragedy, and set himself to effect a revolution in the Italian comic stage. At that time the popular comedies in Italy were really farces, in which pantaloon and harlequin filled the principal rôles, acting with masks on their faces, and trusting very largely to the inspiration of the moment for their buffooneries and pranks. For this style of thing Goldoni determined to substitute the comedy of character according to Molière, and a hard task he set himself. Several years were now spent by him wandering from city to city of North Italy, sometimes practising his profession, but always in

intimate connection with companies of actors, for whom he wrote various comedies, until in 1740 he settled in Venice. Then for twenty years he poured forth comedy after comedy. In 1761 he made an engagement for two years to write for the Italian theatre in Paris, and for that purpose moved to the French capital. On the conclusion of this engagement he was appointed teacher of Italian to the daughters of Louis XV., and remained attached to the court until the Revolution. He died 6th February 1793. Goldoni's comedies, more than 120 in number, some of the best of which are the *Villeggiatura* trilogy, *Locandiera*, *Le Baruffe Chiozzotte*, *Zelinda e Lindoro*, *Ventaglio*, *La Bottega di Caffè*, and *Dama Prudente*, were for the most part put together too rapidly and too roughly to be adjudged first-rate. But, though they seldom touch more than the external and superficial aspects of life and society, they are marked by considerable skill in character-sketching, by faithful representation of contemporary manners, lively dialogue, and cleverness in the invention of comic situations. Goldoni wrote *Mémoires* of his own life (1787), and published at Venice in 1788–89 the first collected edition of his own works in 44 vols. (3d ed. Florence, 53 vols. 1827). His correspondence has been edited by Masi (1880) and Mantovani (1884). See Lives by Molmenti (1879) and Galanti (2d ed. 1883), and Vernon Lee, *Studies of the Eighteenth Century in Italy* (1880).

Goldschmidt, Madame (Jenny Lind), a celebrated Swedish singer, was born of humble parentage at Stockholm, October 6, 1820. Her musical gifts were apparent from her third year, and at nine she was admitted to the school of singing attached to the court theatre, where she received lessons of Berg and others. She sang before the court with success, and at eighteen appeared in the rôle of Agatha in *Der Freischutz*, Alice in *Robert le Diable*, &c., and soon became the principal support of the royal theatre. In June 1841 she went to Paris to receive lessons from Garcia. Meyerbeer, who heard her at this time, prophesied a brilliant future for Jenny Lind. Her voice was tested with success in private in the Grand Opera, and erroneous rumours of failure were current. She had already been engaged for the Stockholm Opera (1842). In 1844 she went to Berlin, and for a time studied German; returning to Stockholm, she was heard with enthusiasm in *Robert le Diable*, and at the instance of Meyerbeer was engaged at Berlin in October, appearing in *Norma* and Meyerbeer's operas. In 1846 she visited Vienna, in 1847 London. Prices at Her Majesty's rose to a fabulous height, and 'the town,' says Chorley, 'sacred and profane, went mad about the Swedish Nightingale.' Her voice at this time has been described as a soprano of bright, thrilling, and remarkable sympathetic quality, with wonderfully developed length of breath, and perfection of execution. She could sing up to high D in rich, full tones, and even touch higher notes; she literally warbled like a bird; and especially striking was her rendering of the weird Swedish melodies. Her return visit to London in 1848 was an immense triumph; and in London, on 18th May 1849, she sang on the stage for the last time in *Roberto;* henceforth her appearances were confined to the concert-room. Her share of the profits of a brilliant concert tour in America under Barnum's management (1849–52), amounting to £35,000, was more than spent afterwards in founding and endowing musical scholarships and charities in her native country. In 1851 she was married at Boston to Otto Goldschmidt, a native of Hamburg, her pianist. Returning to Europe, she continued to sing at concerts and in oratorios, as in London (1856), and for the last time at Düsseldorf (1870). Her English charities included the gift of a hospital to Liverpool and of the wing of another to London. She founded the Mendelssohn scholarship, and her interest in the Bach Choir, of which her husband was conductor, was shown by her careful training of the female chorus. Her voice retained its sweetness to the last, although she did not care to sing much even in the semi-privacy of a crowded drawing-room. But from 1883 till 1886 she was professor of Singing at the Royal College of Music. She died near Malvern, November 2, 1887. Her moral character was elevated and deeply religious; her smile was described as heavenly. See the Memoir by Canon Scott Holland and W. S. Rockstro (2 vols. 1891).

Goldsinny, or Goldfinny (*Crenilabrus melops*), also called the Cork-wing, a small fish of the Wrasse family (Labridæ), common on British coasts. Like other members of its family, it haunts the neighbourhood of rocks, feeding on crustaceans, molluscs, and the like. In colour it is more or less green or yellow, darker above, striped along the sides, with a dark spot on the tail. Like young wrasse, but unlike the adults, it has a serrated bone (preoperculum) on the side of its gill-cover.

Goldsmith, Oliver, was born at Pallas, in Longford, Ireland, on the 10th November 1728, his father, the Rev. Charles Goldsmith, a clergyman of the established church, being at that time curate to the rector of Kilkenny West. When six years old Goldsmith was placed under Thomas Byrne, the schoolmaster described in the *Deserted Village*. After an attack of smallpox, he went successively to various local schools, ultimately entering Trinity College, Dublin, as a 'sizar,' or poor scholar, on the 11th June 1744. As yet he had shown no exceptional ability, nor did he show any at the university. His tutor was rough and unsympathetic; he himself was pleasure-loving and poor. His father died, and his circumstances grew worse. In 1747 he was involved in a college riot, and, escaping from the consequences of this only to fall into further disgraces, finally ran away from his Alma Mater. Matters being patched up by his elder brother, he returned, taking his B.A. degree, 27th February 1749. His uncle, the Rev. Mr Contarine, now his chief friend, wished him to qualify for orders, but he was rejected by the bishop of Elphin. Thereupon he made a false start for America. Getting no farther than Cork, he was next equipped with £50 to study law in London. This disappeared at a Dublin gaming-table. In 1752 he started for Scotland to study physic. Reaching Edinburgh, he stayed there nearly two years, leaving, however, behind him more legends of his social gifts than his professional acquirements. From Edinburgh he drifted to Leyden, again lost at play what little money he had, and finally set out to make the 'grand tour' on foot. After wandering through Flanders, France, Germany, and Italy, and obtaining, either at Louvain or Padua, a dubious degree as M.B., he returned to England in February 1756, with a few halfpence in his pockets. It is thought he tried strolling; it is certain that he was assistant to an apothecary. Then, with the aid of an Edinburgh friend, he practised as a poor physician in Southwark—a profession which he speedily quitted for that of proof-reader to Richardson, in turn abandoning this to be usher in Dr Milner's 'classical academy' at Peckham. At Dr Milner's he became acquainted with Griffiths, the proprietor of the *Monthly Review*, who engaged him as author of all-work. His bondage to Griffiths lasted only a few months. His next mode of subsistence is obscure, but in February 1758 appeared his first definite work, a translation in two volumes of the Memoirs

of Jean Marteilhe of Bergerac, a 'Protestant condemned to the galleys of France for his religion.' For this he used the name of a schoolfellow, James Willington, but the book is known to have been his own. After its appearance he went back to Peckham, to wait for an appointment on a foreign station, which Dr Milner had promised to obtain for him. To procure the funds for his outfit he set about an *Enquiry into the Present State of Polite Learning in Europe*. From some unexplained cause, however, his nomination, when received, fell through, and in December we find him endeavouring to pass at Surgeons' Hall for the humbler post of hospital mate, but without success. What was worse, the clothes he went up in had been obtained on the security of his old employer Griffiths; to pay his landlady he pawned them, and the angry bookseller threatened him with a debtor's prison.

Shortly afterwards, in April 1759, the *Enquiry* was published. It attracted some notice, and better days at length dawned on Goldsmith. He started the periodical called *The Bee* (1759), and contributed to *The Busy Body* and *The Lady's Magazine*. Then came to his miserable lodging in Green Arbour Court, Old Bailey, overtures from Smollett, and John Newbery, the bookseller. For the *British Magazine* of the former he wrote some of his best essays; for the *Public Ledger* of the latter the celebrated *Chinese Letters* (afterwards published as *The Citizen of the World*), which appeared in 1760–61. In May of the latter year he moved to 6 Wine Office Court, Fleet Street, where, on the 31st of the same month, he was visited by Johnson. In 1762, among other things, he published a *Life of Richard Nash*, the Bath master of the ceremonies; and he sold to Benjamin Collins, a Salisbury printer, a third share in the yet-unpublished *Vicar of Wakefield*. In 1764 the 'Club,' known many years afterwards as the 'Literary Club,' was founded; and he was one of its nine original members. His next work was an anonymous *History of England, in a Series of Letters from a Nobleman to his Son*. This was followed in December 1764 by *The Traveller*, a poem which at once raised him to a foremost place among the minstrels of the day. Two years later, in March 1766, appeared *The Vicar of Wakefield*, by which his reputation as a novelist was secured. The stage alone remained untried, and this, after two more years of preface writing and journey-work, he attempted with *The Good Natured Man*, a comedy, produced at Covent Garden in January 1768. It was a moderate success. But he again escaped from enforced compilation (Histories of Rome and England, *History of Animated Nature*) with his best poetical effort, *The Deserted Village* (1770); and three years afterwards achieved the highest dramatic honours by *She Stoops to Conquer*, still one of the most popular of English acting comedies. A year later (April 4, 1774) he died in his chambers at 2 Brick Court, Middle Temple, of a fever, aggravated by the obstinacy with which he had relied upon the popular remedy known as 'James's powder.' He was buried on the 9th, in the burial-ground of the Temple Church, in the triforium of which is a tablet to his memory. The club erected a monument to him in Westminster Abbey. In the year of his death was published the unfinished series of rhymed sketches of his friends, called *Retaliation*, and in 1776 the *jeu d'esprit*, entitled *The Haunch of Venison; an Epistle to Lord Clare*.

Poor in his youth, Goldsmith was not prudent in his more prosperous middle age. He died £2000 in debt, and there is reason for supposing that his difficulties embittered his latter days. When his doctor asked him on his deathbed if his mind was at ease, he replied that it was not. As a man, Goldsmith had some constitutional disadvantages and many obvious faults, mostly of a harmless kind. But he was thoroughly warm-hearted and generous, and full of unfeigned love and pity for humanity. As a writer, in addition to the most fortunate mingling of humour and tenderness, he possessed that native charm of style which neither learning nor labour can acquire. In the felicitous phrase which Johnson borrowed from Fénelon for his epitaph, he touched nothing which he did not adorn. Prior first collected the material for his biography in 1837; in 1848 Forster prepared from this (not without expostulation on Prior's part) his well-known life. Washington Irving's genial sketch of 1849 was based upon Forster. Later memoirs are that by W. Black in the 'Men of Letters' series (1879), and by the present writer in the 'Great Writers' (1888). The last contains a bibliography; and a special bibliography of *The Vicar of Wakefield* is prefixed to the fac-simile edition of that book issued in 1885. The most modern edition of Goldsmith's complete works is that by Gibbs (5 vols. 1884–86).

Goldstücker, Theodor, Sanskrit scholar, was born of Jewish parents on 18th January 1821, at Königsberg, studied there, at Bonn, and at Paris, and established himself as *privat-docent* at Berlin. He came to England in 1850 on the invitation of Professor H. Wilson, and in 1852 was appointed professor of Sanskrit, University College, London, a post he held till his death, 6th March 1872. Founder of the Sanskrit Text Society, he was an active member of the Philological and Royal Asiatic Societies. He wrote all the most important articles on Indian mythology and philosophy (67 in number) in the first edition of this Encyclopædia, and contributed to the *Athenæum* and *Westminster Review*. Of his separately-published works the most notable are *Panini: his Place in Sanskrit Literature* (1861); the Sanskrit text of the Jauninîya-Nyâya-Mâlâ-Vistara (completed by Professor Cowell); and part of a great Sanskrit Dictionary. He projected numerous other works, including a text of the Mahâbhârata, for which he had made vast collections of materials. His *Literary Remains* (2 vols. 1879) comprises, with other papers, the articles contributed to *Chambers's Encyclopædia*.

Gold-thread, the popular name in America for *Coptis trifolia*, a ranunculaceous plant found from Denmark to Siberia, and over the North American continent through Canada into the United States. The leaves are evergreen and like those of the strawberry, but smaller; the flowers are small and white. The name 'gold-thread' is given to the abundant silk-like root-stocks, still a popular remedy among the French Canadians for ulcerated throats.

Goletta (Fr. *La Goulette*), the port of the city of Tunis, from which it is 11 miles N. by rail or canal. In the new quarter are the bey's palace, a large dock, and an arsenal defended by a battery. The population, usually about 3000, is trebled during the visit of the bey in the bathing season; the proportion of Europeans has greatly increased, and many of the houses are now built in the European style. The harbour, though by no means secure, was long the most frequented in Tunis; but after the establishment of a French protectorate some of the trade passed to Bona, in Algeria; and since the completion of the ship canal to Tunis (q.v.), and the deepening of the harbour there in 1893, La Goletta has greatly decayed.

Golf, a Scottish pastime (also *gaff* or *goaf*—the latter the vernacular pronunciation; the name being usually connected with the Dutch *kolf*, 'club'), is

certainly of great antiquity, and frequent references are made to it in old Scottish records. In 1457 the Scottish parliament passed an act enjoining that 'Fute ball and Golfe be utterly cryit downe, and nocht usit, and that the bowe merkis be maid at ilka paroche kirke a paire of buttis, and schuttting be usit ilk Sunday.' A similar act was passed in May 1491. It thus appears that the game was at one time so popular in Scotland that the more important practice of archery, for the defence of the country, stood in danger of being neglected. In 1592 the magistrates of Edinburgh issued a proclamation against playing the game on Sunday.

Reference is made to golf on Leith Links in *A Diurnal of Occurrents within Scotland, 1546–75* (Maitland Club, 1832), and it appears to have been practised by all classes in the reign of King James VI. Charles I. was much attached to the game, and on his visit to Scotland in 1641 was engaged in it on Leith Links when intimation was given him of the rebellion in Ireland, whereupon he threw down his club, and returned in great agitation to Holyrood House. The Duke of York, afterwards James II., also delighted in the game.

Until late years golf was entirely confined to Scotland, though the oldest existing golf club was founded by James I. at Blackheath in 1608; but now it is firmly established south of the Tweed, and clubs have been formed in almost every locality in England where the ground is at all suitable for the game. Golf is played at several stations in India, as well as in Canada and Cape Colony; and clubs were formed at Cairo in 1888 and at San Francisco in 1889. Ladies' golf clubs exist in a flourishing condition at St Andrews, North Berwick, Westward Ho, &c. The game is played on what are called in Scotland *links* (Eng. *downs*)—i.e. tracts of sandy soil covered with short grass, which occur frequently along the east coast of Scotland. The best Scotch golfing links are St Andrews and Leven in Fife, Prestwick in Ayrshire, Machrihanish in Argyllshire, North Berwick and Gullane in East Lothian, Carnoustie and Montrose in Forfarshire, and Dornoch in Sutherland. In England the most important centres are Hoylake near Liverpool, Westward Ho in Devonshire, Wimbledon near London, and Sandwich in Kent. All of these are examples of admirably suited links, as the ground is diversified by knolls, sand-pits, and other *hazards* (as they are termed in golfing phraseology), the avoiding of which is one of the most important points of the game.

A series of small round holes, about four inches in diameter, and several inches in depth, are cut in the turf, at distances of from one to five or six hundred yards from each other, according to the nature of the ground, so as to form a circuit or *round*. The round generally consists of either nine or eighteen holes as the length or nature of the course may allow. The links of St Andrews contain eighteen holes, and two hours are occupied in completing the round. The rival players are either two in number, which is the simplest arrangement, or four (two against two), in which case the two partners strike the ball on their side alternately. The balls, weighing somewhat under two ounces, are made of gutta-percha, and painted white so as to be readily seen.

An ordinary golf-club consists of two parts spliced together—viz. the shaft and head: the shaft is usually made of hickory or lancewood; the handle covered with leather; the head (heavily weighted with lead behind, and with a slip of horn along the front of the sole) of well-seasoned apple-tree or beech. Every player has a *set* of clubs, differing in length and shape to suit the distance to be driven and the position of the ball; for (except in striking off from a hole, when the ball may be *teed*—i.e. placed advantageously on a little heap of sand, called a *tee*) it is a rule that the ball must be struck as it happens to lie. Some positions of the ball require a club with an iron head. The usual complement of clubs is about seven; but those who refine on the gradation of implements use as many as ten, or even twelve, which are technically distinguished as the *driver*, *long-spoon*, *mid-spoon*, *short-spoon*, *brassey*, *putter*, *iron*, *lofting-iron*, *mashie*, *iron-putter*, *cleek*, and *niblick*: the last six have iron heads, the others are of wood. Every player is usually provided with an attendant, called a *caddy*, who carries his clubs and 'tees' his balls. Since the game has become so generally popular, many modifications and inventions in clubs have been introduced. The earliest and most permanent of these is the 'bulger' form of wooden club heads. The bulger-head is shorter and rounder than the old form, and from its general acceptance would seem to have answered its purpose of giving greater power in driving. The others are mostly in the way of iron clubs, and except the 'mashie,' a useful short-headed pitching iron, are too numerous (and in many cases fantastic) to specify.

Club Heads:
1, driver; 2, mid-spoon; 3, putter; 4, cleek; 5, iron; 6, niblick.

Commencing at a spot a few yards in front of the home hole—the *teeing* ground—each player drives off his ball in the direction of the first hole, into which he does his best to put the ball in fewer strokes than his antagonist. If the players put their balls in in an equal number of strokes, the hole is said to be *halved*, and scores to neither; but if one, by superior play, holes his ball in fewer strokes than the other, he gains that hole, and so takes precedence (the *honour*) in striking off towards the next. In this manner they proceed till the entire round is finished, the match being gained by the player who has achieved the greater number of holes. Sometimes the interest of a match is maintained till the very last, by a succession of evenly-played holes, or by each having gained an equal number during the round. 'All even on the day's play' may also be declared where each party has won the same number of rounds as his antagonist, or antagonists. A match may also consist of a certain number of holes independently of rounds, when it of course accrues to the winner of the greater number of holes. In contests between professional players the match usually consists of a certain number of holes to be contested on more links than one.

Throughout the entire game, he whose ball lies farthest from the hole which he is approaching invariably plays before his more advanced companion. We have already said that the player who 'holes' his ball in fewer strokes

than his rival wins that hole. Now, if it is agreed that the match shall fall to the player who holes the entire round in fewest *strokes*, as in playing for medals or other prizes, each stroke is scrupulously recorded, and scored on a card; but if the match is to be yielded to the winner of the *greatest number of holes* in a round, the number of actual strokes need not necessarily be reckoned. Golf, like all other games, has its especial phraseology. Thus, he who is about to play the same number of strokes as his antagonist has already played, plays *the like*; if he is about to play one stroke more than his rival has already played, he plays *the odds*; if one stroke less, he plays *one off two*; if two strokes more, *two more*, and so on. This method of reckoning, though somewhat confusing at first, is after a little time easily acquired; and, from its being universally adopted on golfing courses, should receive especial attention. In the accompanying illustrations the method of holding the club when driving, and the swing, are shown.

Method of holding the Club in driving.

The Swing in driving.

To play the game of golf well requires long practice, and very few attain to great excellence who have not played from their youth. But any one may in a year or two learn to play tolerably, so as to take great pleasure in the game; and for all who have once entered upon it it possesses no ordinary fascination. It has this advantage over many other outdoor games, that it is suited for both old and young. The strong and energetic find scope for their energy in driving long balls (crack players will drive a ball above 200 yards); but the more important points of the game—an exact eye, a steady and measured stroke for the short distances, and skill in avoiding hazards—are called forth in all cases. Along with the muscular exercise required by the actual play, there is a mixture of walking which particularly suits those whose pursuits are sedentary—walking, too, on a breezy common, and under circumstances which make it far more beneficial than an ordinary 'constitutional.'

Golf associations are numerous in Scotland, and in most cases are governed by the rules laid down by the Royal and Ancient Golf Club of St Andrews (1754), which is the chief, and one of the oldest clubs in the country. These rules have been very generally adopted all over England. English golfers are at the same time much indebted to the exertions of the late Mr George Glennie, sometime captain of the Royal Blackheath Golf Club, for keeping the game alive at Blackheath while for many years it was unknown elsewhere in the south; and it was mainly his fostering influence which promoted its growth on other southern greens. Many professional players make their livelihood by golf, and are always ready to instruct beginners in the art, or to play matches with amateurs. Among the most famous professional golfers were Allan Robertson (died 1859), and latterly young Tom Morris (died 1875). 'Amateur' and 'open' championship meetings are held annually on different greens in Scotland and England. The first championships were held alternately by old Tom Morris and Willie Park, sen., for many years. 'Young' Tom Morris was the only player who, winning the trophy three years consecutively, became its permanent possessor.

For information concerning the rules of golf and the history of the game from the earliest records, see *Golf: a Royal and Ancient Game*, by Robert Clark (Edin. 1876; new ed. 1894); *Golfing* (W. & R. Chambers: Edin. 1887); *The Art of Golf*, by Sir W. Simpson (Edin. 1888); *Golf* in the 'Badminton Library,' by H. Hutchinson, A. J. Balfour, A. Lang, Sir W. Simpson, and others.

Golgotha. See CALVARY.

Goliath Beetle (*Goliathus*), a genus of tropical Lamellicorn beetles, in the sub-family Cetoniidæ. They are distinguished by their large size, by the horny processes on the heads of the males, and by

Goliath Beetle.

the toothed lower jaws or maxillæ. Several species frequent tropical and South Africa, and related genera occur in tropical Asia. The male of the largest form, *Goliathus druryi*, from the Gold Coast, measures about four inches in length. In colour, as well as size, these goliaths and their relatives are splendid insects. The family Cetoniidæ

is familiarly represented in Europe and Britain by the Rosechafer (*Cetonia aurata*).

Göllnitz, or GOLLNICZBANYA, a mining town of Hungary, in the county of Zips, 17 miles SW. of Eperies. It has important iron and copper mines, and ironworks. Pop. 4353.

Gollnow, a town of Prussia, in Pomerania, is situated 15 miles NE. of Stettin. It was formerly a Hanse-town; it now has limekilns and a trade in timber. Pop. 8430.

Golomynka (*Comephorus* or *Callionymus baikalensis*), a remarkable fish, found only in Lake Baikal, the only known species of its genus, which comes near the gobies, but is the type of a distinct family. It is about a foot long, is destitute of scales, and is very soft, its whole substance abounding in oil, which is obtained from it by pressure. It may be almost said to melt into oil on the application of fire. It is never eaten.

Goloshes (Fr. *galoche*, 'a patten, clog, or wooden shoe;' from the Low Lat. *calopedia*, 'a clog,' and the Gr. *kalopous*), india-rubber overshoes which were introduced into Great Britain from America about the year 1847. At first clumsily made, and of inferior quality, they were, mainly by the exertions of the Hayward Rubber Company in America, soon much improved in quality and appearance, and the demand for them increased rapidly. The largest manufactory for the production of vulcanised rubber goloshes and other shoes in Great Britain is that of the North British Rubber Company at Edinburgh, where more than 100 distinct kinds of boots and shoes are made, and the production amounts to several thousand pairs a day.

The rubber is (1) torn up into small pieces, washed, and rolled together in granulated sheets; (2) it is then mixed, by the aid of heated rollers, with the vulcanising materials, consisting of sulphur, litharge, lampblack, pitch, rosin, and sometimes other materials; (3) the final stage in the preparation of the material is carried out after the shoes are made, and consists in subjecting them for nine hours to a temperature of between 200° and 300° F. Rubber so treated is said to be vulcanised (see INDIA-RUBBER). The so far prepared sheets of material are again rolled out between the heated rollers, till they are of the required thickness for the shoe uppers. Both soles and uppers for each shoe are cut out separately with a knife. The calico or other linings are coated round the edges with some strongly adhesive cement, probably dissolved rubber, and then all the pieces are ready to be put together. The earlier part of the work is done by men, but women actually make the shoes. A clever girl will make forty pairs a day; a very clever one fifty. That is to make a pair of shoes in ten or twelve minutes.

The chief defect of goloshes is that they keep the stockings constantly damp, and the feet uncomfortable, by preventing the escape or the absorption of the perspiration. Various modifications of the ordinary goloshes are made: thus, there is a kind with warm felt lining; another kind have felt or cloth uppers and ankles, and are often called snow-shoes.

Gomar, FRANCIS, theologian, and leader of the party who opposed most zealously the doctrines of Arminius (q.v.). Gomar, or Gomarus, was born at Bruges, 30th January 1563, studied at the universities of Strasburg, Heidelberg, Oxford, and Cambridge, in the last-mentioned of which he took his degree of B.D. in 1584. In 1594 he was appointed professor of Divinity at Leyden, and signalised himself then and ever after by his vehement antipathy to the views of his colleague, Arminius. At the synod of Dort in 1618 he was mainly instrumental in securing the expulsion of the Arminians from the Reformed Church. He died as professor at Groningen, 1641. An edition of his works was published at Amsterdam in 1645 and 1664.

Gombroon, called also BENDER ABBAS, a seaport of Persia, in the province of Kirman, stands on the Strait of Ormuz, opposite the island of that name. Bender Abbas owed its name and importance to Shah Abbás, who, assisted by the English, drove the Portuguese in 1622 from Ormuz, ruined that seaport, and transferred its commerce to Gombroon. For a while the new town prospered; but at present it is a wretched place of about 8000 inhabitants, mostly Arabs, who trade to the extent of £450,000 per annum in piece goods, sugar, tea, and pottery (imports), and in carpets, wool, tobacco, saffron, opium, almonds, and madder (exports).

Gomera, one of the Canary Islands (q.v.).

Gomorrah. See SODOM AND GOMORRAH.

Gonad, a technical name for reproductive organs. See REPRODUCTION.

Gonaïves, a seaport of Hayti, on a beautiful bay on the west coast, with an excellent harbour, 65 miles NNW. of Port au Prince. It exports coffee, cotton, logwood, and hides. Pop. (1897) 18,000.

Goncourt, EDMOND and JULES DE, a pair of French novelists, born, the former at Nancy, May 26, 1822, the latter at Paris, 17th December 1830. They were not men of letters but artists primarily, and in 1849 they set out knapsack on back to traverse France for drawings and water-colours. Their notebooks made them writers as well as artists, and already in 1852 they had commenced that literary partnership which after twenty years of obscure labours was to conquer the public and stamp its impression upon the modern novel more strongly than any one had done since Balzac. Their earliest serious works were a group of historical studies upon the second half of the 18th century, intended to be an effective resurrection of its habits of life, manners, and costume. With all their elaboration of details these were ineffective and superficial from their lack of the calm and impartial historical sense, to say nothing of the absence of more essential qualities still—breadth of view, and that creative grasp of character by sympathetic insight which is the rarest gift of the historian. The tilting of the 'Castor and Pollux of *bric-à-brac*' against the gigantic figures of the Revolution was almost too pitiful to be amusing. These books were *Histoire de la Société Française pendant la Révolution* (1854), *La Société Française pendant le Directoire* (1855), *Portraits intimes du XVIII^e Siècle* (1856-58), *Histoire de Marie Antoinette* (1858), *Les Maîtresses de Louis XV.* (1860), *La Femme au XVIII^e Siècle* (1862), and *L'Amour au XVIII^e Siècle* (1875). Of much more real value is *Gavarni* (1873), *L'Art au XVIII^e Siècle* (1874), and the later books devoted to Watteau (1876) and Prudhon (1877).

But the important work of the De Goncourt brothers commenced when they assumed the novel as the mould into which to pour the metal of their prolonged and exact observation. Their conception of the novel was that it should be an imaginative attempt to grasp and summarise the results of this; and the task they put before themselves was to unite by means of a plot such as might have happened a multitude of observed facts, and to cast around these an atmosphere which should illumine them. Their aim was to paint manners by taking the traits in which one man resembles a class, rather than to grasp personal character by the points wherein one man is distinguished from another, in the manner of Balzac or George Eliot. Hence they select as generic types only persons of moderate faculties, and herein they are poorer than nature

herself, which not only creates classes and groups but exceptional figures also. Their figures submit to life without subduing it, and are weighed down by that irresoluteness of will and morbid sensitiveness to suffering which is the especial disease of our age. Their subject is not so much the passions as the manners of the 19th century, and their sense of the enormous influence of environment and habit upon man necessitated so close a study of the arts of contemporary life that their work will be valued by future historians as a storehouse of materials. Their descriptive part is always especially prominent, and their stories usually commence without explanation and end without denouement.

The novels in which the brothers carried out their theories display a marvellous unity, despite their double origin. The first, *Les Hommes de Lettres* (1860; new ed. as *Charles Demailly*), was followed by *Sœur Philomène* (1861), *Renée Mauperin* (1864), *Germinie Lacerteux* (1865), *Manette Salomon* (1867), and *Madame Gervaisais* (1869). The last is their greatest novel, the sharp and painful analysis of which was too close a reflex of themselves. Indeed, the weaker of the two did not survive this book, which may be said to have been written with his heart's blood. After the death of Jules, 20th June 1870, Edmond (who lived till 12th July 1896) issued *La Fille Elisa* (1878), *La Faustin* (1882), and *Chérie* (1885). The *Idées et Sensations* (1866) had already revealed to the world their morbid hyper-acuteness of sensation so fatal to nervous health and to that equilibrium of sanity which belonged to Goethe, Victor Hugo, and all the Olympians; and *La Maison d'un Artiste* (1881) had shown their patient love for *bric-a-brac* and its reflex influence upon the mind; but the *Lettres de Jules Goncourt* (1885), and still more the *Journal des Goncourt* (6 vols. 1888–92), have disclosed their conception of fiction and their method of work so fully, that the latter may be accepted as the formal propaganda of a school which embraces many of the foremost novelists of France. See a fine study by Paul Bourget in his *Nouveaux Essais de Psychologie* (1885); and Belloc and Shedlock, *E. and J. de Goncourt* (2 vols. 1892).

Gondar, capital of Amhara in Abyssinia, is situated on a basaltic hill 23 miles N. of Lake Tzana (see ABYSSINIA). Gondar was formerly the residence of the emperor, and at one time had about 50,000 inhabitants; its population numbers at present barely 4000, though there are still some forty churches. The hill is crowned by the ruin of the old castle, built by Indian architects under Portuguese direction; burned by Theodore in 1867, it is now left to the bats and hyænas. The Mohammedan town (Islambed), at the foot of the hill, formerly noticeable for its clean streets and pretty houses, has been deserted in consequence of an edict commanding the baptism of the inhabitants; but the Falashas are permitted to keep their Jewish quarter. Part of the town was burned by the Dervishes in 1889. There are manufactures of fine leather and gold and silver filigree-work, church vessels, and musical instruments; and the priests are masters of penmanship, and prepare religious paintings, reading-desks, and praying-stools. Most of the young priests of Abyssinia are educated here. There is a considerable transit trade.

Gondo koro, a trading post in the country of the Bari negroes, on the Upper Nile, in about 4° 54′ N. lat. A Catholic mission founded here in 1853 was discontinued in 1858 owing to the bad climate and the hostility of the slave-traders. It is now deserted during the greater part of the year, but in December and January merchants arrive and establish an important ivory-market, which was formerly also a centre of the slave-trade. To put this down Baker established a strong military station here in 1871, and changed the name to Ismailia; but, before the abandonment by Egypt of its possessions in Central Africa, Gordon removed the station to Lado, 6 miles lower down the Nile.

Gondola (Ital.), a long narrow boat (averaging 30 feet by 4) used chiefly on the canals of Venice. The prow and stern taper to a point, and curve high out of the water. In the centre there may or may not be a curtained chamber for the occupants.

Venetian Gondola.

The boat is usually propelled by one man standing at the stern, by means of a large sweep very deftly and powerfully handled by the gondolier; or there may be another man at the bow. Immense sums were spent by the wealthy on the luxurious adornment of their gondolas, till in the 16th century sumptuary laws were passed, the consequence of which was that the ordinary gondola came to be of the plainest funereal black, with black cloth cushions and fittings—in Byron's phrase, 'just like a coffin clapp'd in a canoe.'

Gondomar, DIEGO SARMIENTO DE ACUÑA, MARQUIS DE, Spanish ambassador in England from 1613 to 1621. He acquired great influence over King James I., and plied him with all the arts of persuasion to induce him to bring the projected Spanish match, the marriage of Prince Charles with the Infanta, to a successful termination. The ruling motive of his policy was, however, the warmly cherished hope of being able eventually to convert the English nation to Roman Catholicism. See S. R. Gardiner, *Prince Charles and the Spanish Marriage* (1869).

Gonds, a Dravidian people, the most important of the non-Aryan or 'aboriginal' hill-races of the Central Provinces (q.v.) of India. They probably entered the country at an early period from the north, and gave their name to Gondwana, which comprised the greater part of the Central Provinces;

but it was only from the 16th century to the Mahratta invasion in 1741–81 that they ruled the central tableland. To-day they number about a million and a half, and, while the wilder tribes cling to the forest, the rest have made some advances in civilisation. Most of the upper classes are of mixed blood, and many of the race have embraced Hinduism; but, while they carry ceremonial refinements to the extremest limit, they secretly retain many of their old superstitions, with which they have even inoculated their Aryan co-religionists in the territory. The plebeian Gonds are of purer blood, and, as among the other hill-tribes, both sexes limit their necessary attire to a cloth wound about the waist, although the younger people often eke this out with earrings, bracelets, and necklaces. Each village worships the three or four deities it knows best, while admitting the existence of an indefinite number of others. Cholera and smallpox are worshipped everywhere, and the Gonds people the forest, the rivers, and every rock with evil spirits. The name Gondwana is still applied to the tract which they principally inhabit.

Gonfalon (Ital. *gonfalone*), or GONFANON, an ensign or standard (see FLAG), in virtue of bearing which the chief-magistrates in many of the Italian cities were known as *gonfaloniere* (see FLORENCE).

Gong, a Chinese instrument of percussion, made of a mixture of metals (78 to 80 parts of copper, and 22 to 20 parts of tin), and shaped into a basin-like form, flat and large, with a rim a few inches deep. The sound of the gong is produced by striking it, while hung by the rim, with a mallet, which puts the metal into an extraordinary state of vibration, and produces a loud piercing sound.

Gongora. LUIS DE GONGORA Y ARGOTE, Spanish lyric poet, was born at Cordova, 11th July 1561. After a course of study in law at the university of Salamanca, he settled down in his native city to cultivate the poetic talents of which he had already shown conspicuous proofs as a student. About 1614 he entered the church, and became a prebendary of the cathedral at Cordova, and eventually chaplain to Philip III. He died in his native city, 23d May 1627. Gongora's earlier writings—sonnets on a great variety of subjects, lyrical poems, odes, ballads, and songs for the guitar—are inspired with much true poetic feeling. His later works, consisting for the most part of longer poems, such as *Soledades* (or *Solitary Musings*), *Polifemo*, *Pyramo y Thisbe*, are executed in an entirely different and novel style, characterised, especially in respect of diction, by some of the same distinctive features as are found in Euphuism in England and Chiabrerism in Italy. This later style of Gongora, which his followers and imitators designated the *stilo culto*, is florid, pedantic, full of Latin inversions and mythological allusions, pompous, and mannered, and in many places very obscure. His works were never published during his lifetime. The first edition was printed by Vicuña in 1627, good but incomplete; another good one is that of Brussels (1659). See Churton's *Gongora* (2 vols. Lond. 1862).

Goniatites, a genus of fossil cephalopodous mollusca, belonging to the same family as the Ammonites. The genus is characterised by the structure of the septa, which are lobed, but without lateral denticulations, as in Ammonites; they consequently exhibit, in a section, a continuous undulating line. Some forms with slightly waved septa approach very near to the Nautilus. The siphonal portion is shorter than the sides, forming a sinus at the back, as in the Nautilus. The last chamber, the one tenanted by the animal, occupies a whole whorl, and has besides a considerable lateral expansion. The shells are small, seldom exceeding 6 inches in diameter. This genus is confined to the Palæozoic strata: nearly two hundred species have been described from the Devonian, Carboniferous, and Triassic systems.

Gonidia, an old term in lichenology for the green cells (algal constituents) of the thallus. See LICHENS.

Goniometer (Gr. *gonia*, 'an angle;' *metron*, 'a measure'), an instrument used for measuring solid angles, and hence indispensable to the crystallographer. There are two kinds in use, the *contact goniometer* of Carangeau (which is sufficiently accurate for many purposes, but cannot be used in the case of very small crystals), and the *reflecting goniometer* by Dr Wollaston. In skilful hands this instrument can measure the angles of crystals only the hundredth of an inch in size. Several elaborate modifications of this goniometer are now employed by crystallographers.

Gonorrhea (Gr. *gonos*, 'progeny or seed,' and *rheō*, 'I flow'), a name originally applied almost indiscriminately to all discharges from the genital passages in both sexes, but especially in the male. In the course of usage the term has been almost entirely restricted to the designation of one particular kind of discharge, which, from its connection with a contagious poison, was originally called, in strict nosological language, *G. virulenta*. This form of the disease is usually caused by the direct communication of sound persons with those already affected; and accordingly gonorrhea is one of the numerous penalties attending an indiscriminate and impure intercourse of the sexes (see SYPHILIS). Gonorrhea is a very acute and painful form of disease; it is liable, also, to leave its traces in the more chronic form of gleet, which may last for a considerable time. Often, moreover, it leaves some of the parts affected permanently damaged, and stricture, sterility, &c. may result. The only constitutional effect of any importance is a very intractable inflammation of joints, closely resembling rheumatic fever, which occasionally follows it. The name gonorrhea was formed on the erroneous supposition that the discharge consists of the spermatic fluid, whereas, the disease being an inflammation of the mucous membrane of some part of the generative organs, the discharge is the muco-purulent or purulent discharge from the diseased surface. Hence the name *Blennorrhagia* has been proposed for the ailment. The disease may reach its height in a period of from one to three weeks; it then usually subsides, and the various symptoms abate in severity. For gonorrheal ophthalmia, see EYE (DISEASES OF). Victims of gonorrhea and the allied disorders should be warned against consulting any but medical men of high standing and undoubted character.

Gonsalvo di Cordova (the name by which Gonzalo Hernandez y Aguilar is usually known), a celebrated Spanish warrior, was born at Montilla, near Cordova, 16th March 1453. He served with great distinction first in the war with the Moors of Granada, and afterwards in the Portuguese campaign. At the close of the final contest with Granada he concluded the negotiation with Boabdil (Abu Abdallah), king of the Moors, in such a masterly manner that the rulers of Spain bestowed upon him a pension and a large estate in the conquered territory. He was next sent to the assistance of Ferdinand II., king of Naples, against the French. In less than a year Gonsalvo, with his limited resources, had conquered the greater part of the kingdom of Naples, and obtained the appellation of 'El Gran Capitan.' In conjunction with King Ferdinand he succeeded in completely expelling the French from Italy; and in August 1498

he returned to Spain, having received as reward for his valuable services an estate in the Abruzzi, with the title of Duke of San Angelo. When the partition of the kingdom of Naples was determined upon by a compact entered into at Granada, 11th November 1500, Gonsalvo again set out for Italy with a body of 4300 men, but first took Zante and Cephalonia from the Turks, and restored them to the Venetians. He then landed in Sicily, occupied Naples and Calabria, and demanded from the French that, in compliance with the compact, they should yield up Capitanata and Basilicata. This demand being rejected, a war broke out between the two belligerent powers, which was waged with varied success. After the victory of Cerignola, in April 1503, Gonsalvo took possession of Calabria, the Abruzzi, Apulia, even the city of Naples itself, and then laid siege to Gaëta, but was forced to retreat before a superior force of the enemy. On the 29th December of the same year, however, he fell upon them unexpectedly near the Garigliano, and obtained a complete victory. The French army was almost annihilated; the fortress of Gaeta fell; and the possession of Naples was secured to the Spaniards. King Ferdinand of Spain bestowed the duchy of Sesa upon the conqueror, and appointed him viceroy of Naples, with unlimited authority. His good-fortune, however, made him many powerful enemies; and he was recalled to Spain and to neglect. He lived on his estates in Granada till his death, 2d December 1515.

Gontcharoff, Ivan Alexandrovitch (1813–91), Russian novelist, was born a merchant's son at Simbirsk, and for many years was in a government office at St Petersburg. *A Common Story* was translated in 1894; *The Oblomoff* is his masterpiece.

Gonzaga, a princely family which gave a line of dukes to Mantua and Montferrat. The sway of this race over Mantua extended over a period of three centuries, and many of its members were magnificent promoters and cultivators of arts, science, and literature. The Gonzagas gradually monopolised all the chief posts of command, both civil and military; in 1432 they were invested with the title and jurisdiction of hereditary marquises, and in 1530 with that of dukes or sovereigns of the state. After their elevation to ducal dignity they were the faithful champions of the imperial interests in their policy with other states. The House of Gonzaga and that of the Visconti Dukes of Milan were perpetually at war (see Mantua). The marquisate was granted to Giovanni Francesco in 1433. The tenth and last Duke of Mantua, Ferdinando Carlo, who had countenanced the French in the War of the Succession, was deprived by the Emperor Joseph I. of his states, and placed under the ban of the empire. He died in exile in 1708, leaving no issue. A branch of the family ruled Guastalla till 1746.

Gonzaga, Luigi, known as St Aloysius, was born in the castle of Castiglione, near Brescia, 9th March 1568, and was educated at Florence, Mantua, and Rome. Renouncing his marquisate of Castiglione in favour of his brother, he entered the Society of Jesus in 1585. At Rome during a visitation of the plague he gave himself up with wonderful self-devotion to the care of the sick; and, stricken by the malady, died 21st June 1591. He was beatified in 1621, and canonised in 1726. See the *Life of St Aloysius Gonzaga*, edited by E. H. Thompson (1867); the Italian Life by Cepari (trans. by Goldie, 1891); and Aubrey de Vere's *Essays* (1888).

Good, John Mason, physician and writer, was born May 25, 1764, at Epping in Essex, where his father was an Independent minister. He was apprenticed to a surgeon-apothecary at Gosport, next continued his medical studies in London, and commenced practice as a surgeon in Sudbury in 1784. Money difficulties drove him to London in 1793, where he combined medicine with the most miscellaneous literary activity. In 1820 he took his M.D. degree at Marischal College, Aberdeen, and died January 2, 1827. Good's writings embrace poems, translations of Job, the Song of Songs, and Lucretius, essays on prisons, medical technology, and the history of medicine. He collaborated with Dr Olinthus Gregory and Newton Bosworth in the *Pantologia, a New Cyclopædia, comprising a General Dictionary of Arts, Sciences, and General Literature*, in twelve volumes, which was completed in 1813. His ambitious poem, *The Book of Nature*, was published in 1826.

Goodall, Frederick, an English artist, the son of Edward Goodall (1795–1870), an engraver, who early encouraged his son's artistic talents, was born in London, September 17, 1822. He was only seventeen years of age when he exhibited his first picture at the Royal Academy, 'French Soldiers playing Cards in a Cabaret.' 'The Return from a Christening,' which received a prize of £50 from the British Institution, 'Tired Soldier' (1842), 'Village Festival' (1847), 'Hunt the Slipper' (1849), 'Raising the Maypole' (1851), and 'Cranmer at the Traitors' Gate' (1856) are amongst the best of his early pictures. A visit to Venice and Egypt in 1857–59 led him to turn his attention to Italian and oriental subjects, such as 'Reciting Tasso' (1859), 'Song of the Nubian Slave' (1864), 'Rising of the Nile' (1865), 'Mater Dolorosa' (1868), 'Sheep-washing near the Pyramids of Gizeh' (1876), 'Daughters of Laban' (1878), 'Return from Mecca' (1881), 'Flight into Egypt' (1885), and numerous others. Goodall was elected a Royal Academician in 1863.

Good-conduct Pay is an addition to ordinary pay, granted to privates, lance-corporals, and acting bombardiers of the British army. To earn one penny a day the soldier must have served two years without his name having appeared in the regimental defaulters' book, in which serious crimes are recorded. For a second penny six years' service is requisite, and the soldier must have held the first penny for two years without an entry in the regimental defaulters' book—called a 'term of good conduct.' A third penny can similarly be earned after twelve years' service, a fourth after eighteen, and others after periods of five years. Each penny carries with it a badge or Chevron (q.v.) to be worn on the left sleeve. A special rule enables a man who has served without an entry for 14 years continuously to obtain his fourth and succeeding badges and good-conduct pay two years sooner than he otherwise would do. One badge and the pay attached to it is forfeited for every entry in the regimental defaulters' book, but may be regained by a 'half-term of good conduct' (one year) for each badge lost. A soldier who deserts, or is sentenced by court-martial to penal servitude or to be discharged, or by a civil court to imprisonment exceeding six months, forfeits, as a result of the sentence, all his badges and good-conduct pay; and a court-martial may specially sentence him to this forfeiture for any offence. Sergeants and full corporals or bombardiers when reduced to the ranks are allotted the good-conduct pay and badges, less one, which their service would have entitled them to if they had not been promoted, though none is granted to them while non-commissioned officers. Sergeants of distinguished or meritorious service, however, are granted annuities, not over £20 each, receivable during active service, and also on retirement, together with a silver medal inscribed 'for meritorious service,' or 'for distinguished conduct in the

field.'—In the navy very similar rules govern the issue of good-conduct pay, but its amount is limited to threepence a day, and petty officers may hold it.

In the United States the pay of private soldiers increases from $13 to $18 per month according to length of service; and the pay of officers in active service, from chaplain to colonel, increases by 10 per cent. for every five years' service till the completion of twenty years' service.

Goodeniaceæ, an order of corollifloral dicotyledons, closely allied to Campanulaceæ and Lobeliaceæ. The 200 species, the great part herbs, are mostly natives of the Australian and South African regions. *Goodenia ovata* is a pretty yellow-flowered shrub of Australia. *Scævola Taccada* is a shrub from the pith of which the Malays make a kind of rice-paper. The young leaves are eaten as a salad.

Good Friday, the name applied by the Roman Catholic and Anglican Church to the Friday before Easter, sacred as commemorating the crucifixion of our Lord; *paraskeuē*, Holy Friday, or Friday in Holy Week, was its general appellation. This day was kept as a day of mourning, of rigid fast, and of special prayer from a very early period. It was one of the two paschal days celebrated by the Christian church, and in memory of the crucifixion was called by the Greeks *Pascha Staurösimon*, or the 'Pasch of the Cross.' In the Catholic Church the service of this day is very peculiar: instead of the ordinary mass, it consists of what is called the Mass of the Pre-sanctified, the sacred host not being consecrated on Good Friday, but reserved from the preceding day. Formerly all the faithful partook in silence of the eucharist, but at present communion is forbidden on Good Friday, except in the case of the celebrant and of sick persons. The priests and attendants are vested in black; the altar remains stripped of its ornaments, as on Holy Thursday; a wooden clapper is substituted for the bell at the elevation of the host; the priest recites a series of prayers for all classes, orders, and ranks in the church, and even for heretics, pagans, and Jews, though the ministers' genuflexion is omitted before this last petition, in detestation of the feigned obeisance with which the Jews mocked Christ. But the most striking part of the ceremonial of Good Friday is the so-called 'adoration of the cross,' or, as it was called in the Old English popular vocabulary, 'creeping to the cross.' The black covering is removed from a large crucifix which is placed before the altar, and the entire congregation, commencing with the celebrant priest and his ministers, approach, and upon their knees reverently kiss the figure of our crucified Lord. In the eyes of Protestants this ceremony appears to partake more strongly of the idolatrous character than any other in the Roman Catholic ritual; but Catholics earnestly repudiate all such construction of the ceremony (see IDOLATRY, IMAGE-WORSHIP). The very striking office of *Tenebræ* ('darkness') is held upon Good Friday, as well as on the preceding two days: it consists of the matins and lauds of the following day, and has this peculiarity, that by the close all the lights in the church have been gradually extinguished except one, which for a time (as a symbol of our Lord's death and burial) is hidden at the Epistle corner of the altar.

In the Anglican Church also Good Friday is celebrated with special solemnity: proper psalms are appointed, and one of the three special collects is a prayer for 'all Jews, Turks, heretics, and infidels.' In some ritualistic churches the *improperia*, or 'reproaches,' adopted from the Roman service, are sung; and Bach's Passion music is frequently heard. In England and Ireland Good Friday is by law a *dies non*, and all business is suspended; but this is not the case in Scotland or the United States. In Scotland the day until recently met with no peculiar attention, except from members of the Episcopal and Roman Catholic communions; but of late years there have been services in some Presbyterian churches in the larger towns. See also CROSS-BUNS, and CRAMP-RINGS.

Good Hope. See CAPE OF GOOD HOPE.

Goodrich, SAMUEL GRISWOLD, an American author, best known by his pen-name, PETER PARLEY, was born in Ridgefield, Connecticut, 19th August 1793, and edited in Boston an annual called *The Token* from 1828 to 1842, to which he contributed poems, tales, and essays, and in which the best of Hawthorne's 'Twice-told Tales' first appeared. He published some two hundred volumes, mostly for the young, and dealing with history, geography, travels, and natural history. Many of his books were reprinted, and became popular in Great Britain. He died 9th May 1860. See his *Recollections of a Lifetime* (2 vols. New York, 1857).

Goodsir, JOHN, anatomist, was born in 1814, at Anstruther in Fife, studied arts at St Andrews University, and was next apprenticed to a dentist in Edinburgh, attending the medical classes there the while. In 1839 he published a striking essay on the teeth, and next year became keeper of the Museum of the Royal College of Surgeons in Edinburgh, where he lectured on the diseases of bone and cartilage (1842–43). He also investigated the minute structure of the healthy tissues, and was one of the first observers who strongly insisted on the importance, throughout the animal textures, of the cell as a centre of nutrition. His important memoirs on Secreting Structures and on the Human Placenta, and many of his papers in comparative anatomy and natural history, are still of value. Of these a volume was issued in 1845. In 1844 Goodsir was appointed assistant to Dr Monro, professor of Anatomy in the university of Edinburgh, and two years later became his successor. Here he maintained a wide reputation as an anatomical teacher. Ill-health overtook him near the close of his life, and he died 6th March 1867. See the *Memoir* by Professor Turner (1868).

Good Templars, a temperance society founded in the United States in 1852 and introduced into England in 1868. Their organisation is largely modelled on that of the Freemasons, total abstinence principles being furthered by means of lodges, pass-words, grips, and insignia. See TEMPERANCE.

Good-will, when used as a legal term, has two meanings, which have been conveniently distinguished as personal and local good-will. Personal good-will is that interest which is sold along with a profession, and is transferable from one person to another by the recommendation of the seller, and his agreement not to compete with the buyer, as when a doctor or a dentist sells his practice. Local good-will is the saleable interest which attaches to a particular business at a particular place, or, as Lord Eldon defined it, 'the chance that the old customers will resort to the old place,' without the further advantage of personal stipulations with the seller, as in the sale of such a business as 'The Railway Hotel,' 'The Market Shop.' When an old business is transferred the possession of the premises and the old stock (which is necessary to the acquirement of the good-will) is usually regulated by special agreement, and what goes as good-will is the right to carry on the old business, to represent that it is the old business that is carried on, to use the trade name and the trade-mark, and to benefit by the covenants made by the previous owner for the protection of his business.

In a strict view there is no such thing as a transferable good will of so personal a business as a medical, legal, or other professional practice. In the sale of these there ought therefore always to be a stipulation that the seller shall not compete with the buyer by practising in the same locality, or that he shall retire from practice; and that the seller shall introduce and recommend the buyer to his connection as his qualified successor. At first such a covenant was sought to be set aside as invalid, on the ground that it tended to restrain the natural liberty of trade; but the courts have now firmly established that, if a definite radius of moderate length is fixed upon, it does not sensibly restrain trade, inasmuch as the person covenanting can go beyond those limits, and trade as much as he pleases. If the party breaks his covenant he is liable to an action for damages. See Charles E. Allan, *The Law relating to Good will* (1889).

Goodwin Sands, famous sandbanks stretching about 10 miles in a NE. and SW. direction at an average distance of 5½ miles from the east coast of Kent. Large level patches of sand are left dry when the tide recedes, and afford a firm foothold, so that cricket has often been played upon them. When covered the sands are shifting, and may be moved by the prevailing tide to such an extent as to considerably change the form of the shoal. The general outline, however, has been fairly constant, although the survey of 1885 by Staff-commander Tizard, R.N., has demonstrated a tendency to more important motion than usual. The shoal is divided into two principal parts, called the North Goodwin and the South Goodwin respectively, between which is the deep inlet named Trinity Bay, where three steamships have been peacefully anchored at one time. In 1841 it was proposed by W. Bush, C.E., and J. D. Paine, architect, to build a harbour of refuge on the Goodwin Sands by enclosing Trinity Bay with a solid wall of masonry, having a large iron lighthouse at the entrance. The North Goodwin is of irregular semicircular shape, with the curved boundary on its northern or outer edge. The North Sand Head light-vessel is moored a little to the eastward of its northern extreme, exhibits a white flash light, and is about 7 miles distant from Ramsgate. So far back as 1795 a lightship, showing three lights, was moored to the north-east of this shoal. The South Goodwin is in shape somewhat like a crab's claw with its lower part fully extended. The South Sand Head lightship lies off its south-western extremity, and exhibits a double-flash white light. On the western side rides the Gull Stream lightship, displaying a white revolving light. A fourth lightship, known as the East Goodwin, lies 1½ mile to the eastward of the sands, and exhibits a green revolving light. Passing ships not infrequently foul these lightships, notwithstanding the penalty of £50 and expenses to which they become liable. On 30th November 1878 no fewer than three unknown ships in succession ran into the East Goodwin lightship. All four of the lights are visible 10 miles in clear weather. Each vessel is painted red, has her name in bold letters on both sides, and is otherwise distinguished by the disposition of her mast or masts. In foggy weather a fog siren is sounded on the South Sand Head lightship, and gongs are beaten on board the other three. Should a ship be observed standing into danger, warning guns are fired without delay. The Goodwin Sands are also marked by nine buoys moored in well-defined positions around them, and distinguishable from one another by their various colours and shapes. One, the north-east Goodwin buoy, is a Courtenay's self-acting whistle buoy. This admirable system of lightships and buoys has robbed the Goodwins of much of their danger.

These sands have always been dangerous to vessels passing through the Straits of Dover. On the other hand, they serve as a breakwater to form a secure anchorage in the Downs (q.v.) when easterly or south-easterly winds are blowing. The Downs, though safe under these circumstances, become dangerous when the wind blows strongly off-shore, at which time ships are apt to drag their anchors, and to strand upon the perfidious Goodwins. As a rule, wrecks are soon swallowed up by the greedy sands. One ship, the *Ogle Castle*, of 1000 tons burden, entirely disappeared in an hour. In May 1841, however, the ship *Ellison* remained ashore on the North Goodwin for nineteen consecutive tides, and was got off only slightly damaged. The timbers of another wreck were exposed to view at intervals for forty years. Many celebrated wrecks have taken place here, the most terrible having been the loss of an entire fleet of thirteen men-of-war, during the 'great storm' on the night of the 26th of November 1703, on the Sands and neighbouring shore. In two of these, the *Mary* and the *Restoration*, every soul perished. Admiral Beaumont with 1200 officers and men were lost. Many poor wretches got on to the Goodwins when the tide was out, and were seen from the shore. Mr T. Powell, the then mayor of Deal, seized the custom-house boats, and paid five shillings for every man saved. Over two hundred were rescued who would certainly have been overwhelmed by the rising tide. In December 1805 here foundered the *Aurora*, a transport, when no fewer than three hundred persons perished; in December 1814 the *British Queen*, an Ostend packet, was lost with all hands; and in January 1857 the mail-steamer *Violet* was destroyed.

These dangerous sands are said to have once been a low fertile island called Lomea (*Infera Insula* of the Romans), belonging to Earl Godwin, where he lived and kept his fleets; but in 1014, and again in 1099, it was overwhelmed by a sudden inundation of the sea, which also did great damage in other parts of Europe. The tale is that at the period of the Conquest by William of Normandy these estates were taken from Earl Godwin's son, and bestowed upon the abbey of St Augustine at Canterbury. The abbot, having diverted the funds with which it should have been maintained to the building of Tenterden steeple, allowed the sea-wall to fall into a dilapidated condition; and so, in the year 1099, the waves rushed in, and overwhelmed the whole. Tenterden, it should be noted, is an inland place near the south-west frontier of Kent, 15 miles NNE. of Hastings. Thus 'Tenterden steeple was the cause of the Goodwin Sands;' so, at least, says one of the many legends connected with these remarkable shoals. But geology indicates a date long anterior to the catastrophe of the legend.

Difficulty is experienced in finding firm anchorage for the lightships; and all efforts to establish a lighthouse have been hitherto unsuccessful. In 1840 a beacon, having a refuge-gallery at its summit capable of containing forty people, was erected by Captain Bullock, R.N., which stood for some years, and another in 1847 on piles of iron screwed into the sand, on Dr Pott's method, but this was washed away two months afterwards. As soon as a vessel is known to have been driven upon the sands, signal rockets are thrown up and guns fired from the lightships, when one or more of the four lifeboats from Ramsgate, Deal, Walmer, or Kingsdown immediately launch to the rescue, followed usually by 'hovellers'' boats. These 'hovellers,' as the pilots and boatmen of the Cinque Ports are called, show, in seasons of tempest and danger, an intrepidity which is worthy

of all praise. See Gattie, *Memorials of the Goodwin Sands* (1889).

Goodwood, the seat of the Duke of Richmond, 3½ miles NE. of Chichester. An 18th-century building by Chambers and Wyatt, it has a notable collection of portraits; and its park is famous for its cedars and other trees, which in 1754 included 'thirty different kinds of oaks and 400 different American trees and shrubs' (Bishop Pocock's *Travels through England*, Camden Society, 1889). Here is the picturesque racecourse, where the famous Goodwood meeting is held at the end of July, at the close of the London season. It was established in 1802; but its importance (since 1825) was due to Lord George Bentinck's exertions.

Goodyear, CHARLES, an American inventor, was born 29th December 1800, at New Haven, Connecticut. He failed as an iron-manufacturer in 1830, but in 1834 turned his attention to india-rubber, the manufactured products of which had hitherto proved failures because of their liability to soften in the heat of summer. Amid poverty and ridicule, sometimes in prison for debt, he patiently pursued the experiments which, after he had obtained a fresh idea from his assistant Hayward's use of sulphur, ended, in 1844, in the issue of his patent for vulcanised rubber (see INDIA-RUBBER). This process he afterwards perfected, discovering new uses to which his product could be applied, until it required sixty patents to secure his inventions. He received medals at London (1851) and Paris (1855), as well as the cross of the Legion of Honour; although kept in continual litigation and consequent poverty by shameless infringements of his rights, he yet lived 'to see his material applied to nearly five hundred uses, and to give employment, in England, France, Germany, and the United States, to 60,000 persons' (Parton). He died at New York, July 1, 1860. See Pierce, *Trials of an Inventor* (New York, 1866); and Parton, *Famous Americans of Recent Times* (Boston, 1867).

Googe, BARNABY, poet, was born about 1540 at Alvingham, in Lincolnshire, studied both at Christ's College, Cambridge, and at New College, Oxford, then travelled on the Continent, joining on his return the household of his relative Sir William Cecil, and becoming one of the gentlemen-pensioners of Queen Elizabeth. He died in the month of February 1594. He was a friend of George Turberville, and resembled, without equalling, him in the manner of his translations and the metres of his poems. His best works are a series of eight eclogues and his *Cupido Conquered*, which it is not unlikely that Spenser may have seen. A collection of his Eclogues, Epitaphs, and Sonnets was published by Edward Arber in 1871.

Goole, a town and river-port in the West Riding of Yorkshire, is situated at the junction of the Ouse with the Don, 22 miles SSE. of York. The town has since 1829 grown rapidly, and now ranks amongst the chief ports of the kingdom. It possesses extensive docks, which are annually entered and cleared by some 4600 vessels of more than 1,100,000 tons burden. The annual value of the imports amounts to about 4¼ millions sterling, and that of the exports to more than 4¾ millions. Amongst the imports are shoddy for manufacturing purposes, oil, logwood, timber, champagne, farm-produce, and groceries. Coal, cloth, and machinery are amongst the chief exports. There are iron-foundries, alum, sugar, and cordage manufactories, ship and boat building yards, and establishments for sail-making and agricultural machine-making. Pop. (1851) 4722; (1881) 10,418; (1891) 15,413.

Goorkhas, or GURKHAS, since 1769 the dominant race in Nepal, claiming descent from Hindu immigrants, but now almost everywhere commingled with the original Mongolian stock. They fought fiercely and brilliantly in the war of 1814–15. Immediately afterwards three or four battalions were raised for the service of the British power in India. The Goorkhas, who are a short, thick-set race, are brave and faithful soldiers, fought in the Afghan and Sikh wars, and lent valuable aid to the British in the suppression of the Mutiny; and some ten regiments of Goorkhas recruited from Nepal and the borders, now form a most valuable element in our native Indian army. Those from the western districts are much more distinctively a fighting race than those from the eastern parts.

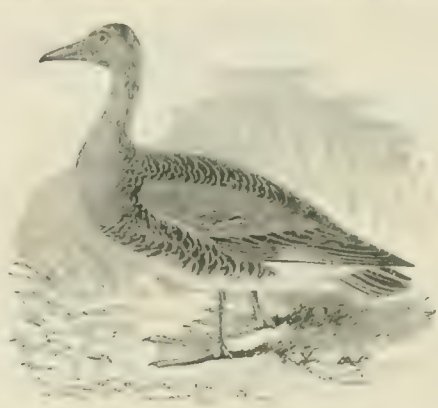
Goosander (*Mergus merganser*), a web-footed bird in the duck family (Anatidæ), in the same genus as the Mergansers, of which it is the largest British representative. The adult male, which measures 26 inches in length, has the head and upper part of the neck of a rich shining green, the feathers of the crown and back of the head elongated, the back black and gray, the wings black and white, the breast and belly of a delicate reddish-buff colour. The bill, legs, and feet are orange-red. The female, which is rather smaller, has the head reddish-brown, with a less decided tuft than the male, and much grayer plumage. The edges of the bill are saw-like above and below, being covered with numerous sharp tooth-like projections directed backwards. The goosander is a native of the Arctic regions, extending into the temperate parts of Europe, Asia, and America.

Goosander (*Mergus merganser*).

In the southern parts of Britain it is seen only in winter, and then only in severe weather, the females and young migrating southwards more frequently than the old males, and not unfrequently appearing in small flocks in the south of Scotland and north of England. In some of the estuaries and fresh-water lakes in the northern parts of Scotland it spends the whole year. It usually nests under a ledge of rock, in the hollow trunk of a tree, or under the shelter of the twisted roots, and lays, about the end of April, eight to thirteen creamy-white eggs. It feeds almost entirely on living fish, which its serrated bill and its power of diving admirably adapt it for catching. The flesh of the goosander is extremely rank and coarse.

Goose (*Anser*), a genus of web-footed birds belonging to the duck family (Anatidæ). The bill is rather high at the base and not longer than the head; the upper part of the beak is slightly hooked, and the lamellæ, characteristic of all the duck tribe, are short, tooth-like, and altogether adapted to

cropping the grass and other herbage on which the geese chiefly feed. The feet are short and completely webbed; the hind toe is present; and the legs are placed comparatively far forward, so that the movements on land are less awkward than those of most ducks. Geese swim little, and never dive. When migrating, or on other long flights, they usually fly in a double line, converging to form a more or less perfect wedge, led by a single gander. The genus is represented by over a dozen species occurring throughout the palæarctic and nearctic regions. Only one species is certainly known to nest in Britain—the Gray Lag-goose (*A. cinereus*)—from which our common domestic goose is believed to be descended. This species used to breed abundantly in the fen districts of England, but has become very rare since the drainage of these parts. It still breeds, though not commonly, in the northern counties of Scotland and in the Hebrides, and large flocks are seen in winter in some of the central counties of Ireland. The nest is placed among heather or on a ledge of rock, and is made of reeds, moss, or grasses. The eggs, usually five to six in number, are surrounded by down plucked by the female from her own breast. The length of the adult male is about 35 inches; of the female, 30 inches; the plumage is grayish-brown on the upper parts, bluish-gray on the wing-coverts, dull white with black markings on the under parts; the feet, legs, and bill are flesh-coloured, and the nail at the tip of the bill is white. This last characteristic is shared by a smaller species, the White-fronted or Laughing Goose (*A. albifrons*), and by it these two may be readily distinguished from the other two common species which have the nail black. The white-fronted goose arrives in Britain every winter in large flocks as soon as severe weather sets in on the Continent. The male measures 27 inches; the prevailing colour is brown. The Bean Goose (*A. segetum*) and the Pink-footed Goose (*A. brachyrhynchus*) are closely allied species,



Bean Goose (*Anas segetum*)

common in many parts of the country from autumn till late in spring. The bean goose is said to exhibit a fondness for newly-sown beans, among which it causes considerable havoc. Its plumage is darker than that of the preceding species; its length is 34 inches. It is readily domesticated. The smaller pink-footed goose has the legs and feet of a pink colour; the bill pink above, black at the base and edges; the nail, as in the bean goose, black.

A great rarity in Britain is the white North American Snow Goose (*Chen hyperboreus*), which is found all over North America, but breeds in the far north. The Canada Goose (*Bernicla canadensis*), found all over North America (where it is the commonest wild goose), is partially domesticated in Europe, where it breeds freely. Among the sea-geese the genus Bernicla, represented by our Barnacle Goose (q.v.) and Brent Goose (q.v.), must especially be noted. In other genera there are many interesting forms which can only be mentioned. The Egyptian or Nile Goose (*Alopochen ægyptiaca*), which is often seen figured on Egyptian monuments, was the 'fox-goose' or 'chenalopex' of the Greeks, so called perhaps on account of the barrows in which it breeds or the fox-like colour of part of its plumage. It is frequently kept in confinement, and finds its nearest relative in the Orinoco Goose (*Alopochen jubata*) of north-east South America. Notable also is the African Spur-winged Goose (Plectropterus), in which the corner of the wing bears a strong spur. Very unique, with sharply-clawed and only slightly webbed toes is the Semi-palmate Goose (*Anseranas semipalmatus*) of Australia, which in habit and anatomy suggests a crane. Also Australian and very peculiar is the sluggish and heavy, thick-billed Cape Barren Goose (*Cereopsis novæ hollandiæ*), rapidly becoming scarce (see CEREOPSIS). Finally this last form leads us to the yet more remote Cnemiornis, which formerly inhabited New Zealand, but having wholly lost the power of flight naturally became extinct.

Although the common goose has been long domesticated, and was probably among the very first of domesticated birds, the varieties do not differ widely from each other. *Emden Geese* are remarkable for their perfect whiteness, *Toulouse Geese* for their large size. As a domesticated bird the goose is of great value, both for the table and on account of its quills and fine soft feathers. The quills supplied all Europe with pens before steel pens were invented, and have not ceased to be in great demand. Geese must have free access to water, and when this is the case they are easily reared and rendered profitable. Two broods are sometimes produced in a season, ten or eleven in a brood, and the young geese are ready for the table three months after they have left the shell. They live, if permitted, to a great age. Willughby records an instance of one that reached the age of eighty years, and was killed at last for its mischievousness. Great flocks of geese are kept in some places in England, particularly in Lincolnshire, and regularly plucked five times a year for feathers and quills. Geese intended for the table are commonly shut up for a few weeks, and fattened before being killed. Great numbers are imported from Holland and Germany for the London market, and fattened in England in establishments entirely devoted to this purpose. Michaelmas is the great goose season. *Goose-hams* are an esteemed delicacy. The gizzards, heads, and legs of geese are also sold in sets, under the name of *giblets*, to be used for pies. The livers of geese have long been in request among epicures both ancient and modern. The *pâté de foie gras* of Strasburg is made from livers in a state of morbid enlargement, caused by keeping the geese in an apartment of very high temperature. See BARNACLE GOOSE, CEREOPSIS, DUCK, SWAN.

Gooseberry (*Grossularia*), a sub-genus of Ribes (see CURRANT), distinguished by a thorny stem, a more or less bell-shaped calyx and flowers on 1-3-flowered stalks. The common gooseberry (*Ribes Grossularia*) is a native of many parts of Europe and the north of Asia, growing wild in rocky situations and in thickets, particularly in mountainous districts; but it is a doubtful native of Britain, although now to be seen in hedges and thickets almost everywhere. There are three main

varieties, formerly regarded as distinct species: (1) *R. Grossularia*, now merely var. *pubescens*, in which the hairs are glandular and cover the berries; (2) var. *uva-crispa*, in which the hairs are non-glandular, and fall off the berries before ripening; (3) var. *reclinatum*, in which hairs are found only on the leaf-margins. The varieties produced by cultivation are very numerous, chiefly in England, where, and particularly in Lancashire, the greatest attention has been paid to the cultivation of this valuable fruit-shrub. In the south of Europe it is little known. It does not appear to have been known to the ancients. Its cultivation cannot be certainly referred to an earlier date than the 17th century, and was only in its infancy at the middle of the 18th, when the largest gooseberries produced in Lancashire scarcely weighed more than ½ oz., whereas prize gooseberries now sometimes reach 2 oz. Many well-known diversities of form, colour, and flavour, as well as of size, mark the different varieties. For the production of new varieties the gooseberry is propagated by seed; otherwise, generally by cuttings, which grow very freely. Any good garden soil suits the gooseberry. It is rather the better for a little shade, but suffers from much. The bushes are trained in various ways, but it is necessary to prune so that they may not be choked up with shoots; yet care ought to be taken to have an abundant supply of young wood, which produces the largest berries. Summer rather than winter pruning is now largely recommended. Besides its well-known wholesomeness and pleasantness, and its use for making an excellent preserve and jelly, the ripe fruit is used for making wine and vinegar. An effervescent gooseberry wine, which might well claim attention under its own name, is often fraudulently sold as champagne. The use of unripe gooseberries for tarts increases the value of this fruit-shrub. The gooseberry season is prolonged by training plants on north walls, and by covering the bushes with matting when the fruit is nearly ripe. Unripe gooseberries may be kept in jars or bottles, which are closely sealed while heated to expel air, and placed in a cool cellar, to be used for tarts in winter.

Various derivations have been given of the name gooseberry, but most probably the first syllable is a corruption of *groscille*, the French name of the fruit, from which also comes the Scotch *grozet* or *grozart*. Attempts to introduce the European gooseberry into North America have invariably failed, owing to the appearance, sooner or later, of mildew among the plants. Among the other species or varieties most worthy of notice are *R. oxyacanthoides*, extending across the upper North American continent from the Atlantic to the Pacific, and now largely grown for market in the middle states; *R. divaricatum* and *R. irriguum*, both of north-west America—all agreeable, though small and more or less acid; *R. gracile*, found in mountain-meadows from New York to Virginia, with blue or purplish berries of exquisite flavour; *R. aciculare*, a Siberian species, with sweet, well-flavoured yellowish or purplish smooth berries; all of which, and probably others, seem to deserve more attention than they have yet received from horticulturists.—The Snowy-flowered Gooseberry (*R. niveum*), a native of America, is remarkable for its beautiful white pendulous flowers. Its berries in size and colour resemble black currants, and make delicious tarts. *R. speciosum*, from the same region, is very ornamental.—*R. saxatile*, of Siberia, and other species, forming the sub-genus Botrycarpum, have a character intermediate between currants and gooseberries, being prickly shrubs, with their berries in racemes.—The so-called Cape or Peruvian Gooseberry is a Physalis (q.v.). For the Coromandel Gooseberry, see CARAMBOLA. —The GOOSEBERRY BUG is the Harvest Bug (q.v.).

Gooseberry Caterpillar, a name applied to the larvæ of two very different insects, both injurious to gooseberry and currant bushes. (1) The Magpie Moth (*Abraxas grossulariata*), appearing about midsummer, has usually a black head, yellow

The Magpie Moth (*Abraxas grossulariata*): *a*, caterpillar; *b*, chrysalis.

body, and white wings spotted with black. From eggs laid on the leaves of the above-mentioned bushes caterpillars hatch in September, feed for a brief space, and then hide themselves till May or June of the next year. The caterpillar is a 'looper,' drawing itself up into a peculiar curve when alarmed, and has a black head, creamy body with some stripes of reddish-orange along the side and elsewhere, and with a row of black spots along the middle line of the back. After a period of voracity, it spins a transparent cocoon and passes into a chrysalis, 'yellow at first, but afterwards shining black, with orange-coloured rings.' Care of the bushes, syringing with various washes, and gathering the torpid caterpillars are the usual means of prevention and remedy. (2) More destructive than the above is the larva of the Gooseberry Sawfly (*Nematus ribesii*), which plays havoc with the leaves of our bushes. The female sawfly appears about April and lays her eggs on the leaves. The grubs hatch in a week or less, and eat small round holes first in the leaf on which they are born, then all over the bush. The adult fly is a yellowish insect with transparent wings, and measures about a third of an inch in length. The larva is bluish-green,

Gooseberry Sawfly (*Nematus ribesii*): *a*, adult fly; *b*, natural size; *c*, larva; *d*, pupa.

with black head, feet, tail, and spots, with twenty feet, and a length of about three-fourths of an inch when full grown. At maturity they drop from the bushes, and bury themselves in the ground to undergo their metamorphoses. The grubs of late summer broods remain as such, but within cocoons, throughout winter, finishing their metamorphoses as the gooseberry bushes are becoming leafy in spring. Miss Ormerod recommends removing the surface soil in early spring from under the bushes, treatment with lime, picking off attacked leaves, drenching the bush with warm water not hot enough to hurt the leaves, dusting with flour of sulphur, &c. Dusting with

hellebore powder is dangerous to those who may eat the berries from which the poison has not been removed. In regard to both these practically important insects, consult Miss Ormerod's *Manual of Injurious Insects* (Lond. 1881).

Goose-fish, a common name in America for the Angler-fish (see ANGLER). The American Goose-fish (*Lophius americanus*) is one of the best known of the five species of Lophius, grows to a length of 4 to 5 feet, and weighs from 15 to 170 lb. It is dark brown above and dirty white below, is hideous in appearance (being also known as 'wide gab' and 'devil-fish'), and has a most voracious appetite, preying indifferently on all kinds of fish, and eating occasionally fowls, such as gulls and ducks. It is practically useless for any purpose.

Goosefoot. See CHENOPODIUM.

Goosegrass. See CLEAVERS.

Gopher, a name in use in some parts of America for various kinds of ground squirrel (see CHIPMUNK), for the Prairie Dog (q.v.), for the Pouched Rat (q.v.), and even for the land tortoise of the southern states.

Gopher Wood. The probable identity of the gopher wood of Scripture with the Cypress (q.v.) is affirmed on account of the qualities of the wood, and on account of the agreement of the radical consonants of the names.

Göppingen, a town of Württemburg, 26 miles by rail ESE. of Stuttgart, has a 16th-century castle, a mineral spring (alkaline carbonic acid), and carries on manufactures of woollen cloth, paper, toys, &c. Pop. 14,337.

Gopura. See INDIA, p. 109.

Gorakhpur, capital of a district in the North-west Provinces of India, on the Rapti, 430 miles NW. of Calcutta, with an active trade in grain and timber. Pop. (1891) 64,980.—The flat, well-watered district of Gorakhpur has an area of 4598 sq. m., three-fifths of which is cultivated, and a fourth under forest. Pop. (1891) 2,994,057, nine-tenths Hindus.

Goramy, or GOURAMI (*Osphromenus olfax*), a fish of the family Anabasidæ or Labyrinthi-branchidæ, a native of the Eastern Archipelago, highly esteemed for the table, and introduced on that account into India, Mauritius, Cayenne, and the French West India Islands. Its form is deep in proportion to its length, the head small, and terminating in a rather sharp short snout, the mouth small, the tail rounded, the dorsal and anal fins having numerous rather short spines, the first ray of the ventral fins extending into a very long filament; it attains the size of a large turbot. It is sometimes kept in large jars by the Dutch residents in Java, and fed on water-plants. It was introduced into Mauritius about the middle of the 18th century, and soon spread from the tanks in which it was at first kept into the streams, multiplying abundantly. The goramy is interesting also on other accounts. It is one of the nest-building fishes, and at the breeding season forms its nest by entangling the stems and leaves of aquatic grasses. Both the male and female watch the nest for a month or more with careful vigilance, and violently drive away every other fish which approaches, till the spawn is hatched, afterwards affording a similar parental protection to the young fry.

Gordian Knot. The traditional origin of this famous knot was as follows. The Phrygians, seeking a king, were informed by the oracle at Delphi that they were to choose the first person they met riding on an ox-cart towards the temple of Zeus. That person was Gordius, a poor peasant, who accordingly was elected king. He afterwards dedicated his car and yoke to Zeus, in the acropolis of Gordium (a city named after himself), and tied the knot of the yoke in so skilful a manner that an oracle declared whoever should unloose it would be ruler of all Asia. When Alexander the Great came to Gordium, he cut the knot in two with his sword and applied the prophecy to himself.

Gordianus, the name of three Roman emperors, father, son, and grandson.—The first, MARCUS ANTONIUS GORDIANUS, was descended by the father's side from the famous family of the Gracchi. After being ædile, in which capacity he celebrated gladiatorial sports with great magnificence, he twice filled the office of consul. On the conclusion of his second term of office he was appointed proconsul of Africa. He was a man of modest and gentle manners, great liberality, and refined literary taste. The tyranny and injustice of the Emperor Maximinus at length excited a rebellion in Africa, the authors of which proclaimed Gordianus emperor, although he was then (238) in his eightieth year. At the same time his son was conjoined with him in the exercise of imperial authority. The younger Gordianus, however, was defeated and slain in battle by Capellianus, viceroy of Mauritania, before Carthage, whereupon his father put an end to his own existence, having been emperor for little more than a month.—MARCUS ANTONIUS GORDIANUS, grandson of the preceding, was raised to the dignity of Cæsar along with Pupienus and Balbinus, who were also elected emperors in opposition to Maximinus; and, in the same year (238), after the three last named had all fallen by the hands of their own soldiers, Gordianus was elevated by the Prætorian bands to the rank of Augustus. Assisted by his father-in-law, Misitheus, a man distinguished for his wisdom, virtue, and courage, whom he made prefect of the Prætorians, Gordianus marched in 242 into Asia, against the Persians, who under Shahpûr (Sapor) had taken possession of Mesopotamia and had advanced into Syria. Antioch, which was threatened by them, was relieved by Gordianus; the Persians were driven back beyond the Euphrates; and Gordianus was just about to march into their country when Misitheus died. Philip the Arabian, who succeeded Misitheus, stirred up the soldiery to assassinate the emperor (244).

Gordius. See HAIR-EEL.

Gordon, THE FAMILY OF. This great Scottish historical house takes its origin and name from the lands of Gordon in Berwickshire. The first traces of it are found in the beginning of the 13th century, when Gordons witnessed charters by the Earls of Dunbar and March, and granted lands and pasturages to the monks of Kelso. In 1305 Sir Adam of Gordon held under King Edward I. of England the office of joint-justiciar of Lothian, and sat at Westminster as one of the representatives of Scotland. He was among the last to join the banner of Bruce, who rewarded his adherence by a grant of the northern lordship of Strathbogie. The grant failed of effect at the time; but it was renewed by King David II. in 1357, and by King Robert II. in 1376. Under this last renewal Sir John of Gordon, the great-grandson of Sir Adam, entered into possession, and so transferred the chief seat of the family from the Merse and Teviotdale to the banks of the Dee, the Deveron, and the Spey. The direct male line came to an end in his son Sir Adam, who fell at Homildon in 1402, leaving an only daughter to inherit his lands, but transmitting his name through two illegitimate brothers—John of Gordon of Scurdarg, and Thomas of Gordon of Ruthven—to a wide circle of the gentry of Mar, Buchan, and Strathbogie, who, calling themselves

'Gordons,' styled the descendants of their niece 'Seton-Gordons.'

Dukes of Gordon.—Elizabeth of Gordon, the heiress of Sir Adam, married before 1408 Alexander of Seton (son of Sir William of Seton), who before 1437 was created Lord of Gordon. Their son Alexander, who took the name of Gordon, was made Earl of Huntly in 1449, and Lord of Badenoch a few years afterwards. He acquired by marriage the baronies of Cluny, Aboyne, and Glenmuick in Aberdeenshire; and had grants from the crown of the lordship of Badenoch and other lands in Inverness-shire and Moray. He died in 1470, and was succeeded by his second son George, who had married Annabella, daughter of King James I., and who added to his territories the lands of Schivas in Aberdeenshire, and Boyne, Enzie, and Netherdale in Banffshire. He was chancellor of Scotland from 1498 to 1501, and, dying soon afterwards, was succeeded by his son Alexander, the third earl, who acquired Strathaven (or Strathdoun) in Banffshire, and the Brae of Lochaber in Inverness-shire. He commanded the left wing of the Scottish army at Flodden. Dying in 1524, he was succeeded by his grandson George, the fourth earl, who acquired the earldom of Moray, held the offices of lieutenant of the north and chancellor of the realm, and was reputed the wisest, wealthiest, and most powerful subject in Scotland. The crown, counselled to clip his wings lest he should attempt, like the Douglases in the previous age, to overawe the throne, stripped him of the earldom of Moray, and, rushing into revolt, he fell (or died of apoplexy) at Corrichie in 1562. Sentence of forfeiture was pronounced upon his corpse, but was rescinded in 1565, and his son George succeeded as fifth earl. He died in 1576. His son George, the sixth earl, was conspicuous as the head of the Roman Catholics in Scotland. He defeated at Glenlivet a royal force sent against him under the Earl of Argyll in 1594, but, submitting to the king, obtained an easy pardon, and was made Marquis of Huntly in 1599. He died in 1636. His son George, the second marquis, espoused the royal cause in the great civil war of his time. 'You may take my head from my shoulders,' he said, in answer to tempting offers from the Covenanters, 'but not my heart from my king.' When he resided in Aberdeen in 1639 he was attended daily by twenty-four gentlemen, of whom three were barons, while eight gentlemen guarded his mansion by night. He was beheaded at Edinburgh in 1649. His son Lewis, the third marquis, was restored by King Charles II. in 1651, but died in 1653. His son George, the fourth marquis, was created Duke of Gordon in 1684. He held the castle of Edinburgh for King James VII. at the Revolution; and, dying in 1716, was succeeded by his son Alexander, the second duke, who died in 1728. He lived, Boswell says, 'in sequestered magnificence, corresponding with the grand-dukes of Tuscany,' with whom he believed that he could count kindred. His son Cosmo George, the third duke, died in 1752, leaving three sons. The youngest, Lord George Gordon (q.v.), led the Protestant mob which sacked London in 1780; the eldest, Alexander, who became fourth duke, was the author of the well-known song, 'Cauld Kail in Aberdeen.' His wife, the sprightly Jane Maxwell, daughter of Sir William Maxwell of Monreith, was even more noted for her beauty than her wit, and was known as the 'beautiful Duchess of Gordon' (died 1812). The fourth duke died in 1827, and was succeeded by his son George, the fifth duke, on whose death, without issue, in 1836, the title of Duke of Gordon (being limited to the heirs-male of the body of the first duke) became extinct, the title of Earl of Huntly fell into abeyance, and the title of Marquis of Huntly was adjudged to the Earl of Aboyne, as heir-male of the body of the first marquis. The estates went to the duke's nephew, Charles, fifth Duke of Richmond and Lennox, grandson of the fourth Duke of Gordon. Elizabeth, Duchess of Gordon (1774–1864), widow of the fifth duke, long survived her husband, and was a woman of noble character and eminent piety (see her *Life and Letters*, by A. M. Stuart, 1866). The title of Duke of Gordon was revived in 1876 in the person of the sixth Duke of Richmond.

Marquises of Huntly.—Lord John Gordon, second son of the first Marquis of Huntly, was made Viscount of Melgund and Lord Aboyne in 1627. Three years afterwards he was burned to death in the tower of Frendraught. In 1632 his elder brother George was made Viscount of Aboyne, which title, on his succession to the Marquisate of Huntly in 1636, devolved on his son Lord James, who distinguished himself on the king's side during the wars of the Covenant, and died, it is said, of a broken heart, a few days after the execution of King Charles I. in 1649. His younger brother, Lord Charles Gordon, was made Earl of Aboyne in 1660; and his great-great-grandson, George, who had been a favourite at the court of Marie Antoinette, succeeded as fifth Earl of Aboyne in 1794, on the death of his father, and as ninth Marquis of Huntly in 1836, on the death of the fifth Duke of Gordon. In 1853 the ninth marquis was succeeded by his eldest son Charles, tenth marquis, who died in 1863, and the marquisate of Huntly and earldom of Aboyne fell to his eldest son Charles, eleventh marquis.

Earls of Sutherland.—About the year 1512 Adam Gordon of Aboyne, second son of the second Earl of Huntly, married Elizabeth, the heiress of Sutherland, and was progenitor of the Gordon Earls of Sutherland, who bore the surname of Gordon till the beginning of the 18th century, when they exchanged it for that of Sutherland, which had been borne by the earlier earls.

Lochinvar and Kenmure.—William of Gordon (1306-29), the second son of Sir Adam of Gordon, was the progenitor of the knightly family of Lochinvar, which in 1633 was raised to the peerage by the titles of Lord of Lochinvar and Viscount of Kenmure. William, the sixth viscount—the 'Kenmure's on and awa'' of Jacobite song—was beheaded in 1716 for his share in the rising of the previous year. The peerage, then forfeited, was restored in 1824, but has been in abeyance since the death of Adam, the ninth viscount, in 1847.

Earls of Aberdeen.—According to old tradition this house descends from one of the illegitimate brothers of Sir Adam of Gordon, who was slain at Homildon in 1402. Its first authentic member was Patrick Gordon of Methlic, who died on the banks of the Ythan in 1445. In 1642 its chief, Sir John Gordon of Haddo, was created a baronet of Nova Scotia. He was beheaded at Edinburgh in 1644, bequeathing the name of 'Haddo's Hole' to one of the aisles of St Giles' Church, which had been his prison. His son, Sir George Gordon of Haddo, became a Lord of Session in 1680, Lord President in 1681, and Lord Chancellor in the following year. He was raised to the peerage in 1682, by the titles of Earl of Aberdeen, Viscount of Formartine, Lord Haddo, Methlic, Tarves, and Kellie. He died in 1720 with the character of being 'a solid statesman, a fine orator, speaking slow but strong.' Some of these lineaments, it has been thought, reappeared, with his love of letters, in his great-great-grandson, the fourth Earl of Aberdeen (q.v.). Among other members of the house of Gordon not mentioned above were Colonel John Gordon, one of the assassins of Wallenstein; Gordon Pasha; and, through his mother, Lord Byron.

See Poolbeers. There is a MS. *Historie Chronologique de l'Origine et Progrez des Gordons Ecossois* (1545), by an Italian monk, Ferretus; a MS. *Genealogie of Gordons Earles of Huntlie and Gordons com in Scotia*, by Gordon of Straloch (died 1661); and histories of the house by William Gordon (1727) and C. A. Gordon (1754). See the more valuable *Genealogical and Historical Memoirs of the Earls of Sutherland* which has much on the Gordons, by Sir Robert Gordon of Gordonstoun (written 1630, published 1813, with continuation).

Gordon, Adam Lindsay, the first of Australian poets, was born at Fayal in the Azores in 1833, the son of a retired army captain. At twenty he sailed to Adelaide to push his fortune, and tried in turns, but without success, sheep-farming, 'over landing,' and cattle driving in South Australia, emerging to light in Melbourne as the best gentleman steeplechase rider in the colony. His broken circumstances and religious hopelessness deepened the natural gloom of his temperament, and at length he threw up the struggle, and blew out his brains at Brighton, a marine suburb of Melbourne, 24th June 1870. He had published in 1867 *Sea spray and Smoke drift*, a very unequal volume, yet containing a few admirable lyrics reflecting closely the sombre colour of his life and the passionate despair that at last drove him to the refuge of death. His *Ashtaroth, a Dramatic Lyric* (1867), was an ambitious attempt at a task for which his powers were inadequate, only relieved from absolute failure by the beauty of the lyrics with which it is interspersed. His last volume, *Bush Ballads and Galloping Rhymes*, appeared, it is said, on the very day of his unhappy death, with a dedication to Major Whyte-Melville. The opening poem, 'The Sick Stock-rider,' is a marvellously vivid transcript from the bush-life he knew, steeped with the irresistible pathos of reality. 'How we beat the Favourite' is said to be the most popular poem in Australia, and certainly it is the best ballad of the turf in the English tongue, unequalled in its kind for fire and speed.

See A. P. Martin's article in *Temple Bar* for 1884 (vol. lxx.), Marcus Clarke's introduction to the complete edition of Gordon's poems, and D. B. W. Sladen's *Australian Poets* (1888).

Gordon, Charles George ('Gordon Pasha'), was born at Woolwich, 28th January 1833, fourth son of General Gordon, Royal Artillery, by his wife Elizabeth Enderby, and descended from the Gordons of Park, a cadet branch of the House of Huntly. From school at Taunton he passed in 1847 to the Military Academy, Woolwich; in 1852 entered the Royal Engineers; and saw his first active service in the trenches before Sebastopol, where he served from January 1855 to the end of the siege, being once slightly wounded. After the fall of the south side Gordon proceeded to Kinburn, returned again to Sebastopol, and was employed in the demolition of the docks and destruction of the forts; and he was subsequently engaged in surveying the new frontier between Turkey and Russia in Europe and Asia. In 1860 he went to China and took part in the capture of Peking and the destruction of the famous Summer Palace near that city. In 1863 he was appointed to the command of a Chinese force officered by Europeans and Americans, and during that and the following year was engaged almost incessantly against the Taiping rebels in the rich provinces of Cheh-kiang and Chiang-sû. In two campaigns he fought thirty-three actions and took numerous walled towns, crushing the formidable rebellion which had so long wasted the fairest provinces of China. This feat of arms achieved in the space of eighteen months, and at a cost of only £200,000, placed the young major of engineers in the foremost rank of the soldiers of his day. Returning from China in 1865, 'as poor as when he had entered it,' he was appointed to the ordinary engineer duties at Gravesend, where he remained for six years, devoting the greater part of his spare moments to relieving the want and misery of the poor, visiting the sick, teaching, feeding, and clothing the many waifs and strays among the destitute boys of the town, and providing employment for them on board ship. In 1872 he quitted Gravesend for Bulgaria, where he remained as commissioner on the Danube for nearly two years.

At the close of 1873 he accepted employment under Ismail, Khedive of Egypt, and, proceeding to the Soudan, took up the work which Sir Samuel Baker had begun two years earlier—that of opening up the vast regions of the equatorial Nile, and the lakes which recent exploration had discovered. In these distant and unhealthy regions he remained for three years, overcoming by extraordinary energy and resolution all difficulties of nature, hostile man and climate. A chain of posts was established along the Nile; steamers were brought from Egypt in sections, put together above the last rapid, and the navigation of Lake Albert Nyanza successfully accomplished. Underlying all this labour there was in Gordon's mind a purpose beyond gain or exploration. It was the abolition of the slave-trade which heretofore had been the one great object of Soudanese commerce. Discovering that his efforts to suppress this trade must remain unsuccessful unless his power extended to the vast plain countries lying west of the Nile basin—Kordofan and Dar-Fûr—Gordon returned to Egypt and England in 1876.

Going out again in January 1877, he was appointed by the Khedive sole governor of the entire Soudan, with unlimited powers over a region that stretched from the second cataract of the Nile to the Great Lakes, and from the Red Sea to the head-waters of the streams that fall into Lake Tchad. During the next three years he traversed in all directions this vast territory. Now he was settling a frontier dispute with the Abyssinian feudatories in the east; now swooping down with scanty escorts upon some slave raider or rebellious chieftain in western Dar-Fûr. For months together he seemed to live on the back of his camel. Neither the numbers of his enemies nor the fiercest sun of terrible deserts could check his energy. His presence, multiplied by incessant toil into twenty times the reality, awed the wild tribes into obedience, and for the first time in its history the Soudan seemed to feel that law and justice were united with government. Early in 1880 all this ceased. Gordon resigned his command. A great change was coming in Lower Egypt, and it was evident that under the new system which was being inaugurated at Cairo there could be no place for such a master. A short visit to India, continued on to the old scene of his first famous enterprise in China, filled up the greater portion of 1880; but the close of the year found Gordon in Ireland intent upon relieving the almost chronic unhappiness of that island. Struck with the terrible scenes of poverty which he witnessed in the south and west of the island, he propounded a scheme of land-law improvement, which, although then met with ridicule or silence, has since been largely made the basis of legislation; but these views did not tend to make their holder acceptable in the eyes of authority, and, to escape the necessity of accepting some insignificant routine appointment at home, Gordon volunteered to take another officer's duty in the Mauritius, where for another year he remained unnoticed and unthought of.

From Mauritius Gordon proceeded to the Cape

in colonial employment, and finally returned to England in the close of 1882. Almost the whole of the following year was spent by him in Palestine in unbroken quiet and reflection. Early in 1884 he was asked by the British government to proceed once more to the Soudan, where the events which had taken place in Egypt since he quitted it four years before had given rise to a long catalogue of catastrophe. The Moslem populations had risen in revolt, defeating the armies of Egypt and isolating her garrisons. To remove these garrisons from the Soudan was the primary object of Gordon's mission; that accomplished, he was to proclaim the separation of the country from Egyptian rule. But all this was changed by the hard logic of facts. A month after Gordon reached Khartoum that place was invested by the troops of the Mahdi, the leader of the Soudan revolt. Then began what may truly be called the supremely heroic period of Gordon's life. The world seemed to recognise that a great man was in the throes of a great peril. In an age when merit is rarely found unobtrusive, and when genius is apt to exhibit its light on the house-top, Gordon, whose whole life had been one endeavour to depreciate his own merit and to deny himself the glory of his actions, became at once the centre of perhaps the widest attention given in our time to one man. After the siege of Khartoum had lasted five months a relief expedition was organised in England. In September the advance up the Nile began. Early in November the troops entered the Soudan at the Second Cataract, the greater portion of the expedition moving in boats built in England for the passage of the upper cataracts, many of which had never been navigated by any craft. After two months of very arduous labour the advance, crossing the desert from Korti, and finding at the latter place some of Gordon's steamers, arrived in the end of January 1885 in the neighbourhood of Khartoum. It was too late. The place had been taken by the Mahdi two days earlier. Gordon had fallen. One thing, however, was gained by the toil and blood of this expedition. It was the journal kept by Gordon during the latter half of the siege. From this journal he stands before us—as in no other way could he have been revealed to us—a wonderful instance of courage, faith, resolution, and humility; a man from whose life and death we gather that, amid all the change of science and system, the mould in which the true hero is cast remains the same.

See Andrew Wilson's *Ever Victorious Army* (1868); Birkbeck Hill's *Gordon in Central Africa* (1881); Gordon's own *Reflections in Palestine* (1884), *Last Journals* (1885), and *Letters to his Sister* (1888); and the Lives of him by Hake (*The Story of Chinese Gordon*, 2 vols. 1884–85), Arch. Forbes (1884), by his brother, Sir Henry Gordon (1886), Sir W. F. Butler (1889), D. Boulger (1896), and the books on the Egyptian Soudan by Ohrwalder (trans. 1892) and Slatin Pasha (trans. 1896).

Gordon, Lord George, was born in London, 26th December 1751, the third son of the third Duke of Gordon. From Eton he entered the navy, and rose to be lieutenant, but quitted the service during the American war, after a dispute with the Admiralty. Elected in 1774 M.P. for the pocket borough of Ludgershall, Wiltshire, he presently attacked both sides with such freedom as to give rise to the saying that there were 'three parties in parliament—the ministry, the opposition, and Lord George Gordon.' Still he displayed considerable talent in debate, and no deficiency of wit or argument. A bill having, in 1778, passed the legislature for the relief of Roman Catholics from certain penalties and disabilities (see Catholic Emancipation), the Protestant Association of London was, among other societies, formed for the purpose of procuring its repeal, and in November 1779 Lord George was elected its president. On 2d June 1780 he headed a vast and excited mob of 50,000 persons, who, decked with blue cockades, marched in procession from St George's Fields to the House of Commons to present a petition for the repeal of the measure. Dreadful riots ensued in the metropolis, lasting five days, in the course of which many Catholic chapels and private dwelling-houses, Newgate prison, and the mansion of the chief-justice, Lord Mansfield, were destroyed. The magistrates feared to read the Riot Act, but at length on the 7th, when thirty-six fires were blazing at once, the troops were called out by the king, and everywhere drove the rioters before them, 210 being killed, 248 wounded, and 135 arrested, of whom 21 were afterwards executed. Property to the amount of £180,000 had been destroyed in the riots, a vivid description of which is given in Dickens's *Barnaby Rudge*. Lord George himself was tried for high-treason; but Erskine's defence got him off on the ground of absence of treasonable design. His subsequent conduct seemed that of a person of unsound mind. Having, in 1786, refused to come forward as a witness in a court of law, he was excommunicated by the Archbishop of Canterbury for contempt. In 1787 he was convicted, on two official informations, for a pamphlet reflecting on the laws and criminal justice of the country, and for publishing a libel on Marie Antoinette and the French ambassador in London. To evade sentence he retired to Holland, but was sent back to England, and apprehended at Birmingham. He died in Newgate of fever, 1st November 1793, having latterly become a proselyte to Judaism. There is a vindication of him by Dr Robert Watson (1795).

Gordon, Sir John Watson, Scottish portrait-painter, son of Captain Watson of the royal navy, was born at Edinburgh in 1788. His training in art was got in the studios of his uncle, George Watson, and Sir Henry Raeburn. At first he essayed imaginative subjects, but on Raeburn's death in 1823 he stepped into his place as the first portrait-painter of Scotland. Three years later he took the surname of Gordon; in 1850 he was elected president of the Royal Scottish Academy and knighted, and in 1851 he became a London Royal Academician. Gordon was as national in his art as it is possible for a portrait-painter to be; and nearly every man of note in Scotland, besides not a few in England, sat to him for their portraits. Among his best-known works may be mentioned 'Sir Walter Scott,' 'Dr Chalmers,' 'Earl of Dalhousie,' 'Sir Alexander Hope,' 'Lord President Hope,' 'Sir John Shaw Lefevre,' and 'the Provost of Peterhead.' The last picture gained the gold medal at the French Exhibition of 1855. Gordon was not a distinguished colourist, grays and quiet hues being predominant in his pictures. He died at Edinburgh, 1st June 1864.

Gordon, Lucie, Lady Duff, a clever writer, was the only child of John Austin, the jurist, and of Sarah Taylor, his wife, and was born in London, 24th June 1821. In 1826 she went with her parents to Germany, whence, after two years' stay, she returned, speaking German like her native language. At Boulogne in 1834 she met Heine, an acquaintance renewed with tender pathos twenty years later, when Heine was dying at Paris. In 1840 she became the wife of Sir Alexander Duff Gordon. In 1842 she gave to the world the first of her long series of translations from the German, Niebuhr's *Gods and Heroes of Greece*. This was followed by the *Amber Witch*, begun 1843; the *French in Algiers*, published 1845; and Feuerbach's *Remarkable Criminal Trials*, 1846. In 1849, in conjunction with her husband, she translated Ranke's *House of*

Brandenburg. In 1850 appeared her translation of Wailly's *Stella and Vanessa*; in 1853 she translated Comtesse d'Arbouville's *Village Doctor*, and, together with her husband, Ranke's *Ferdinand and Maximilian*. In the midst of her busy life alternating between translation work and the choicest society, her health gave way, and she was advised to try the climate of the Cape of Good Hope. Thence, 1861–62, were penned her genial and vivacious *Letters from the Cape*. After her return to England in 1862 she the same year visited Egypt for the sake of her health. She returned to England, June 1863, but was forced again to retreat to Egypt the same year. She died at Cairo on 14th July 1869, and was buried in the cemetery there. Her *Letters from Egypt* (1863) and *Last Letters from Egypt* (1875), observant and bright and cheerful, form perhaps her best contribution to literature. See Janet Ross, *Three Generations of Englishwomen* (1889).

Gordon, Patrick, soldier of fortune, was born at Easter Auchleuchries, on the coast of Aberdeenshire, 31st March 1635. Brought up by his mother as a Catholic, at sixteen he sailed from Aberdeen to Danzig, and entered the Jesuit college of Braunsberg. His restless temper could not long endure the stillness and austerity of that retreat, and, making his escape from it in 1653, he led for some time an unsettled life, until in 1655 he enlisted under the flag of Sweden, then at war with Poland. During the six years that he took part in the struggle between these two powers he was repeatedly made prisoner, and as often took service with his captors, until again retaken. He had risen to the rank of captain-lieutenant, when he resolved to try his fortune next with the czar, and in 1661 joined the Muscovite standard. Here his services in disciplining the Russian soldiers gained him rapid promotion—lieutenant-colonel in 1662, and colonel in 1665. Hearing that the death of his elder brother had made him 'goodman of Auchleuchries,' he wished to return to Scotland; but there was no escape from the Russian service. The czar, however, sent him on a mission to England in 1666. On his return he fell into disgrace; but during 1670–76 he was engaged in subduing the Cossacks in the Ukraine, in 1677 in defending Tschigirin against the Turks and the Tartars. His gallant performance of that duty procured him the rank of major-general. In 1683 he was made lieutenant-general; in 1685 obtained leave to visit England and Scotland. James II. wished him to enter the English service; but it was in vain that he petitioned for leave to quit Russia. In 1688 he was made general, and now began his intimacy with the Czar Peter, who, in the following year, owed to Gordon's zeal and courage his signal triumph over the conspirators against his throne and life. In 1698 he crushed the revolt of the Strelitzes during the czar's absence from Russia. On 29th November 1699 he died at Moscow. See Dr Joseph Robertson's edition of *Passages from the Diary of General Patrick Gordon* (Spalding Club, 1859).

Gordon Bennett, Mount, a mountain seen in Africa by Mr Stanley in 1875. It lies south of Albert Nyanza, a little north of the equator and east of 30° E. long. It is a truncated cone, probably an extinct crater, and rises 14,000 or 15,000 feet in height. It is sometimes covered with snow. See Ruwenzori.

Gordonia, a genus of Ternstrœmiaceæ. *G. Lasianthus*, the Loblolly Bay, which covers considerable tracts of swampy coast in the Gulf of Mexico, is a handsome tree (50 to 60 feet), with evergreen leaves, and large white fragrant flowers. The bark is used in tanning.

Gore, Mrs Catherine Grace, a clever and prolific English novelist, daughter of Mr Moody, wine-merchant, was born at East Retford, Nottinghamshire, in 1799. In 1823 she was married to Captain Charles Arthur Gore, with whom she resided for many years on the Continent, supporting her family by her literary labours. These were varied and voluminous to an extraordinary degree, amounting in all to more than seventy works. She died at Lynwood, Hants, January 29, 1861. Her first published work was *Theresa Marchmont* (1823). Some of her early novels, as the *Lettre de Cachet*, and the *Reign of Terror* (1827), were vivid descriptions of the French Revolution; but her greatest successes were her novels of English fashionable life, conspicuous among which were *Cecil, or the Adventures of a Coxcomb* (1841), and *Ormington* (1842). *The Ambassador's Wife*, *The Banker's Wife*, &c. She also wrote *The Rose Fancier's Manual* (1838). Mrs Gore's books are clever. She had seen much of the world both at home and abroad, and was never at a loss for characters or incidents. The chief feature of her novels is the lively caustic pictures of fashionable and high society, but they are wanting in genuine feeling and simplicity.

Gorée, a small island in French Senegal, lying immediately south of Cape Verd, is almost entirely covered by the town of Gorée, an unhealthy place of (1885) 2200 inhabitants. Its commercial importance is rapidly being transferred to the port of Dakar, which lies over against it on the mainland.

Gorey, a municipal borough and market-town of County Wexford, 59 miles S. of Dublin by rail, and 3 miles inland from St George's Channel. Pop. (1851) 2973; (1891) 2213.

Görgei, Arthur, commander-in-chief of the Hungarian forces during the revolt of 1849, was born at Toporcz, in the county of Zips, 5th February 1818. On the outbreak of the revolt in 1848, Görgei at once offered his services to the Hungarian independent government, and first distinguished himself by compelling Jellachich's Croatian reserve of 10,000 men to capitulate to him at Ozora, on 7th October. After this exploit he was given a command against Windischgrätz on the western frontier. But, driven back by the Austrian general to Raab by 26th December, and learning that Budapest had fallen and the government had fled to Debreczin, Görgei made a wide detour through the mountains to the north of the capital, and joined his troops to the army in the neighbourhood of Debreczin. Of this force Görgei was made commander-in-chief in the end of March 1849. Then, advancing westwards to the relief of Komorn, which still held out against the Austrians, he decisively routed the enemy in a succession of battles between April 2 and April 10. On April 22 he effected the relief of the beleaguered city, and four days later routed the Austrians so thoroughly at Uj-Szöny that they were compelled to evacuate the country. Meanwhile a new Austrian army was being equipped, and the Russians were invading the country from the north and north-east. At this critical period Görgei wasted valuable time in the siege of Ofen (Buda). After offering an obstinate but unavailing resistance to the Austrians in several battles near Komorn, Görgei was again compelled to retreat eastwards; but at Waitzen he encountered the Russians. Still retreating, by way of Tokay, he reached in the beginning of August Grosswardein, where he again suffered defeat from Paskevitch, the Russian general. On 11th August he was nominated dictator in Kossuth's stead at Arad, and two days later surrendered his army of 24,000 men, the last of the Hungarian forces in the

field, unconditionally, to the Russian commander Rüdiger, at Világos, near Arad. Görgei himself was imprisoned for some time at Klagenfurt, in Carinthia, but eventually set at liberty. His countrymen (including Kossuth) accused him of treachery, a charge to which he replied in *Mein Leben und Wirken in Ungarn in 1848 und 1849* (Leip. 1852). With Kossuth and the civil government he failed all along to act in cordial sympathy and harmony, and he is also said to have shown personal jealousy of the other Hungarian generals. He returned to Hungary in 1868, and in 1884 was presented with an address by 260 of his old companions in arms.

Gorges, Sir Ferdinando, styled 'the father of colonisation in America,' was born about 1565 at Ashton, in Somersetshire. He founded two Plymouth companies (1606–20 and 1620-35) for acquiring and planting lands in New England, and in 1639 received from the king a charter constituting him proprietor of Maine. He adhered to the king in the Civil War, and died some time in 1647. His son neglected the province, which finally placed itself under the jurisdiction of Massachusetts, to which colony Sir Ferdinando's grandson sold his rights in 1677 for £1250.

Gorgias, a celebrated Greek rhetorician and sophist, of the time of Socrates, was born at Leontini, in Sicily, and came to Athens as ambassador from his native city in 427 B.C. He subsequently settled in Greece, and, becoming famous as a teacher of eloquence, travelled from place to place, acquiring wealth as well as fame. He died at Larissa about 380, more than a hundred years old. He seems to have drawn the extremest consequences of the sophistic negativism; teaching that nothing is, and if it were, it would be unknowable, and if there were such a thing as knowledge, it would be uncommunicable (see Sophists). Plato's Dialogue *Gorgias* is written against him. Of a large work by him on Nature nothing remains. Two works attributed to him are extant, the *Apology of Palamedes*, and the *Encomium on Helena*, but their genuineness is disputed. The best edition is by Blass (Leip. 1871).

Gorgo, or Gorgon, according to Homer, a frightful female monster inhabiting the infernal regions. Hesiod mentions three Gorgones—Stheno, Euryale, and Medusa, of whom the last named is the chief inheritor of the characteristic attributes of the single Homeric Gorgon. Their habitation was on the brink of the Western Ocean, in the neighbourhood of Night and the Hesperides; but Herodotus and other later writers place it in Libya. They were generally represented as winged virgins with brazen claws and enormous teeth, having on their heads serpents in place of hair, and two serpents round their bodies by way of girdle. According to later legends, Medusa was originally a very beautiful maiden, and the only one of three sisters who was mortal. Having become a mother by Neptune in one of Minerva's temples, that virgin goddess changed her hair into serpents, which gave her so fearful an appearance that whoever looked on her was turned into stone. She was slain by Perseus, and her head placed in the shield of Minerva.

Gorgonia, a genus of corals of the Alcyonarian type, in which the colony of polypes forms a branched but flattened growth, supported by an internal axis of horn (*cornein*) originally derived from the bases of polypes. The genus, which includes over a score of widely distributed species, is nearly allied to the black coral (*Plexaura antipathes*) of the Red Sea and Indian Ocean, from the black horny axis of which ornaments are often made; and to the sea-fan (*Rhipidogorgia flabellum*), the much branched fan-like skeleton of

Sea-fan.

which is often brought home as a curiosity from the West Indies.

Gorgonzola, a village (pop. 4000) 12 miles NE. of Milan, with a fine church, silk manufactures, and trade in a special kind of cheese.

Gorham, George Cornelius (1787–1857), vicar of Brampford Speke, in North Devon, and hero of the 'Gorham case' (1848–50), which arose when Dr Phillpotts, Bishop of Exeter, refused to institute him on a presentation by the Lord Chancellor. The bishop found him to be of unsound doctrine as to the efficacy of the sacrament of baptism; inasmuch as he held that spiritual regeneration is not given or conferred in that sacrament, and in particular, that infants are not made therein 'members of Christ and the children of God,' as the catechism and formularies of the church declare them to be. The case was brought before the Arches Court of Canterbury, which decided (1849) that baptismal regeneration is the doctrine of the Church of England, and that the appeal must be dismissed with costs. From this decision Gorham appealed to the judicial committee of Privy-council. That court found that differences of opinion on various points left open were always thought consistent with subscription to the articles, and that opinions in no important particular to be distinguished from Gorham's had been maintained without censure by many eminent prelates and divines: the court therefore decided that the judgment of the Arches Court should be reversed, and Gorham was, after some further litigation, instituted to Brampford Speke. During the two years that the suit was pending the theological question was discussed with acrimony in sermons and pamphlets.

Gorhambury. See Bacon (Francis).

Gorilla (*Troglodytes Gorilla*), a great African ape, generally referred by naturalists to the same genus with the chimpanzee, although Professor Isidore Geoffroy St-Hilaire has attempted to establish for it a separate genus. It has received the name by which it is now known in consequence of its being supposed to be the same animal which is mentioned in the *Periplus* of Hanno the Carthaginian navigator, who visited the tropical parts of the west coast of Africa about the year 350 B.C., although it is by no means certain that the gorilla of Hanno is not the chimpanzee, or perhaps a species of baboon. Vague accounts of apes of great size, of which very wonderful stories were told,

were from time to time brought from Western Africa; but it was not till 1847 that the gorilla became really known to naturalists, when a skull was sent to Professor Wyman of Boston by Dr Wilson, an American missionary on the Gaboon River. Since that time not only have skeletons and skins been obtained in sufficient number for scientific examination, but information has also been procured concerning the habits of the animal in his native haunts. The accounts of the gorilla given in Du Chaillu's *Explorations and Adventures in Equatorial Africa* (Lond. 1861) soon came to be regarded by the highest scientific authorities, and particularly by Owen, as in the main trustworthy, notwithstanding all the doubt that was cast over that traveller's narrative of his adventures; and they are in accordance with all that has been learnt from other sources, and with the inferences to be deduced from the dentition and osteology of the animal.

The gorilla differs from the chimpanzee in its greater size; the height of an adult male in an erect posture being commonly about 5 feet 6 inches or 5 feet 8 inches, although there is reason to think that it sometimes exceeds 6 feet. The general aspect of the creature may be gathered from the accompanying figure. The skin is very black;

Gorilla (*Troglodytes Gorilla*).

the hairy covering of the back is thicker than on the belly; its colour varies in individual and on different parts of the body from reddish-brown to black.

The skeleton is very powerful and massive, and differs from the human skeleton in the following (among other) points. The skull is extremely prognathous, the supra-orbital ridges are enormously developed; there is a great crest between the frontals and parietal bones which joins the occiput crest. The canine teeth are very large, particularly in the male. The cervical vertebræ have very long spinous processes. The ribs increase progressively in their span, the chest cavity being thus more or less conical in form. The arm bones are much longer than in man, while the leg bones are shorter.

The muscular anatomy shows also certain marked differences from man, as does also the brain. The gorilla cannot be regarded as nearer to man than the chimpanzee and orang. There are a number of varieties of the gorilla, but apparently only one species, which is confined to the forests of West Africa between 2° N. and 5° S. lat., and 6° and 16° E. long. It is principally a vegetable feeder, though like most apes it also preys upon small mammals, birds, and their eggs.

Hand (*a*) and foot (*b*) of Gorilla.

The gorilla wanders about in families, consisting of one male and female and their young; most of the time is spent upon the ground, though the animal is a skilful climber. It is not so ferocious a creature as has been supposed, and when molested generally avoids an encounter; but if driven into a corner it will defend itself, and its enormous strength renders it a dangerous enemy. On such occasions it will advance to the attack, beating its breast with its fists and giving forth a furious roar. The gorilla has not been hitherto tamed, and, in an adult state at least, seems very incapable of it. In 1876 a live gorilla was brought to Berlin, the first authentic instance of the introduction of the animal into Europe; and in 1887 a young gorilla was exhibited at the Zoological Gardens in the Regent's Park. The name given to this animal in its native country is *N'gina*, or *Ingena*. On the Loango coast it is called *N'pungu*. For the skeleton, see ANTHROPOID APES, and the books there cited.

Gorkum (Dutch *Gorinchem*), a fortified town of South Holland, on the Merwede, 22 miles ESE. of Rotterdam, possesses an arsenal, some manufactures, and a miscellaneous trade. Pop. 12,300.

Görlitz, a town of Prussian Silesia, is situated on a declivity on the left bank of the Neisse, 49 miles W. of Liegnitz. One of its old mural towers, the Kaisertrutz, is now the guard-house and armoury. Among the beautiful Gothic churches the most interesting is that of St Peter and St Paul, built 1423-97, with five naves. Outside the town is the Kreuzkapelle, an imitation of the Holy Sepulchre at Jerusalem, built 1481-89. A railway viaduct, upwards of 2720 feet in length and 118 feet high, here crosses the valley of the Neisse. Görlitz has manufactures of cloth, which is its staple, cotton, linen, and fictile wares, with iron-foundries and machine-shops. Here Jacob Boehme spent most of his life and died. Pop. (1843) 15,200; (1890) 62,135, mostly Protestants. Görlitz was taken and held alternately by the Swedes and the Imperialists during the Thirty Years' War.

Görres, JAKOB JOSEPH VON, a distinguished German author, was born at Coblenz, 25th January 1776. In common with most of the ardent youth of the time, Görres threw himself eagerly into the movement of the French Revolution; and a journal established by him, *Das Rothe Blatt*, advanced the most extreme opinions of the time. In 1799 he went to Paris as the chief of a deputation to negotiate the annexation of the Rhine-land to the French Republic, but in Paris became convinced of Napoleon's despotism. On his return to Germany he settled down as a lecturer on physics in his native town, and devoted himself exclusively to literature for several years. In 1807 he published the first part of his well-known collection of German *Volksbücher;* and in 1810 his work on Asiatic mythology. From these studies, however, he was aroused to the hope of liberation

from French tyranny by the reverses of the French arms in the Russian expedition. Appealing to the national sentiment of his countrymen in the *Rheinischer Merkur*, he became, in truth, the literary centre of the national movement. After the re-establishment of German independence Görres denounced the encroachments of domestic absolutism with the same energy, until, having drawn upon himself the displeasure of the Prussian government, he was obliged to flee to France, and afterwards to Switzerland. In 1827 he accepted the professorship of the History of Literature in the university just founded at Munich by the liberal King Louis of Bavaria. His later years were devoted to literature, and to the controversies as to mixed marriages and Hermesianism (see HERMES). He was the founder of the Catholic journal, *Die Historisch-Politischen Blatter*. His chief work was his *Christliche Mystik* (1842; new ed. 1879). He died 29th January 1848. An edition of his works (9 vols.) appeared between 1854 and 1874. See the Life by Sepp (1876).

Gortschakoff, PRINCE ALEXANDER MICHAELOVITCH, Russian statesman, was born at St Petersburg, 16th July 1798, being the son of Prince Michael, a distinguished officer. He was educated at the celebrated Lyceum of Tzarskoe-Selo, and acquired experience in diplomacy under Nesselrode. Ambassador at Vienna (1854–56), he displayed great judgment and ability during the Crimean war, and it was chiefly through his influence that Russia agreed to the treaty of Paris. After this event Prince Gortschakoff succeeded Nesselrode as minister of foreign affairs. When France became hostile to Austria on the Italian question, he cultivated the friendship of the former. Desirous of restoring the prestige of Russia in European affairs, he addressed a circular dispatch to the Powers in 1860 in favour of the principle of nationalities in the Two Sicilies. He also favoured the French expedition of 1861 to Syria on behalf of the oppressed Christians, but he declined to associate himself with France and Great Britain in their unfriendly attitude towards the United States after the outbreak of the civil war. Touching the Polish insurrection of 1863, he repudiated foreign dictation, and asserted the right of Russia to settle her internal affairs in accordance with her own interests and the integrity of the empire. By this step he acquired great popularity at home and respect abroad, and he was appointed chancellor of the empire in July 1863. From this time until the ascendancy of Bismarck he was the most powerful minister in Europe.

He remained neutral during the struggle between Prussia and Austria; and, owing to a definite understanding between the Russian and Prussian chancellors, the neutrality of Austria was secured in the great Franco-Prussian war of 1870. Gortschakoff further availed himself of this war to counteract the injury done to Russian influence by the treaty of Paris. At the London Conference in January 1871 he procured the revision of the treaty, and the formation of another putting an end to the neutralisation of the Black Sea. For this service the emperor conferred upon him the dignity of Serene Highness. In 1873–74 he manifested a desire to preserve friendly relations with England in regard to central Asia, but this was scarcely consistent with his aggressive policy. In the Servian war of 1878 Gortschakoff took up an indecisive attitude; and after the conclusion of the Turko-Russian war, the repudiation of the treaty of San Stefano, and the signing of the treaty of Berlin his influence began to wane. At the Berlin Congress Bismarck and Beaconsfield had paid more attention to Schouvaloff than to the chancellor. Gortschakoff altogether ceased to be the first factor in European politics before Alexander II. was assassinated, and long before he was superseded by M. de Giers as minister for foreign affairs in March 1882. Gortschakoff's sphere of action was European, not local; he ignored too much Russian developments and Russian aspirations, took no active interest in the serious financial and industrial problems affecting his country, or in the growth of Nihilism, and he even failed to bear his part in the abolition of serfdom. After his retirement he left Russia for Baden-Baden, where he died on 1st March 1883. Gortschakoff was a man of considerable culture and a friend of the liberal arts. His diplomatic circulars were remarkable for their excellent diction, their wit, and their resistless logic. The name is also Englished by *Gortchakoff* and *Gorchakov*. See Klaczko's *Two Chancellors* (Eng. trans. 1876).

Gortschakoff, PRINCE MICHAEL, cousin of the above, was born in 1795, and served against the French in 1812–14 and against the Turks in 1828–29. In the war of the Polish revolution of 1831 he greatly distinguished himself, and was made general of artillery. He was appointed military governor of Warsaw in 1846, and took part in the invasion of Hungary in 1849. On the outbreak of the Crimean war he twice commanded the Russian army despatched to the Danubian Principalities, on the second occasion leading the retreating Russian forces into Bessarabia after the raising of the siege of Silistria. In 1855 he was appointed commander-in-chief in the Crimea and southern Russia. He was defeated on the Tchernaya, but recovered his laurels by his gallant defence of Sebastopol, and by his skilful retreat to the North Fort after the blowing up of the fortress. Alexander II. appointed him governor of Poland in 1856, and he was engaged in carrying out the conciliatory policy of the czar when his death occurred on May 30, 1861.

Gory Dew, a dark-red slimy film sometimes seen on damp walls and in shady places. Its appearance on the whitewashed walls of damp cellars, &c. is apt to occasion alarm from its resemblance to blood. It is one of the lowest forms of vegetable life, an alga of the group Palmellaceæ, and allied to the plant to which the phenomenon of Red Snow (q.v.) is due. Its botanical name is *Porphyridium cruentum* (*Palmella cruenta*). See PALMELLACEÆ, and ALGÆ.

Görz, capital of the Austrian crown-land of Görz-Gradisca, in the Küstenland, is charmingly situated in a fruitful plain, near the Isonzo, 35 miles NNW. of Trieste by rail. Shut in by mountains on all sides except the south, it enjoys an almost Italian climate, and has of late years acquired some fame as a health-resort. Among its principal buildings are the old castle of the former Counts of Görz and the former Jesuit college, both now used as barracks; the cathedral, with a beautiful sacristy; and the prince-bishop's and several other palaces. The surrounding plain is covered with vineyards, and industries are the cultivation and export of fruit and wine, whilst Görz's specialty has long been the printing of Hebrew books for the East. There are dyeworks, and important manufactures of flour, sugar, cotton, silks, rosoglio, paper, leather, soap, and matches. In a Franciscan cloister close by are the graves of Charles X. of France (q.v.), the Duc d'Angoulême and his wife, and the Comte de Chambord. Pop. (1869) 16,659; (1890) 21,825. See Schatzmayer, *Der Kurort Görz* (1886). The Austrian Illyrian Küstenland ('Coastland') includes the principality of Görz-Gradisca, the margraviate of Istria, with the Quarnero Islands, and Trieste and its territory. Its boundaries are the Adriatic on the south, and

on the remaining sides Venice, Carinthia, Carniola, and Croatia. Area, 3075 sq. m.; pop. (1880) 647,943; (1890) 695,394.

Goschen, GEORGE JOACHIM, English statesman, son of a London merchant of German extraction, was born in London, August 10, 1831, and was educated at Rugby and Oriel. He is LL.D., D.C.L., F.R.S., and P.C. In 1863 he wrote on exchange, and entered parliament as a Liberal for the City of London. When Lord Russell, after Palmerston's death, reorganised the Liberal ministry, he appointed Goschen Vice-president of the Board of Trade, November 1865. In the following January the latter entered the cabinet in consequence of his appointment as chancellor of the Duchy of Lancaster. When Gladstone became prime minister in 1868, Goschen took office as President of the Poor-law Board, but three years later became the head of the Admiralty, which post he retained until the fall of the Gladstone ministry in 1874. Goschen's next public work was the regulation, in conjunction with Joubert, of the Egyptian finances (1876). Then in 1878 he represented Great Britain at the international monetary conference held at Paris, and, two years afterwards, as ambassador extraordinary to the Porte, enforced on Turkey the fulfilment towards Greece of the treaty of Berlin. He strenuously opposed Home Rule; in 1887–92 was Unionist Chancellor of the Exchequer, and in 1888 converted part of the National Debt. In 1895–1900, as First Lord of the Admiralty, he made provision for increasing the navy. He has published works on finance (*Foreign Exchanges*, 16th ed. 1894), education, &c., and has been Lord Rector of Aberdeen and Edinburgh Universities. He sat for London, 1863–80; Ripon, 1880–85; East Edinburgh, 1885–86; and St George's, Hanover Square, 1887–1900, when he retired from public life. His grandfather was the famous Leipzig bookseller, Georg Joachim Goschen (1752–1828).

Goshawk (lit., 'goose-hawk') (*Astur*), a genus in the family Falconidæ, nearly related to the sparrow-hawks (Accipiter), and like the latter distinguished from the falcons proper by not having a toothed or notched bill. The British species (*A. palumbarius*) is now only a visitor, and a rare one. It is common in the forests of northern and central Europe, and ranges as far east as Japan, and as far south as Morocco and Egypt. It is a rapacious bird, following small mammals and game-birds in swift, persistent, and rapidly altered flight. The prevalent colour of the plumage is ashy brown; the size of the females, which are decidedly the larger, is about two feet. The nest is large, built of sticks, and placed in a tree. The eggs (four) are bluish-gray in colour, and laid in April or May. The goshawk used to breed in Britain, and though termed 'ignoble' was employed in Falconry (q.v.) for hunting ground-game, on which it naturally preys.

Goshawk (*Astur palumbarius*).

The goshawk of the northern United States (*A. atricapillus*) is larger and handsomer, but otherwise very like the European species. Audubon describes its meteor-like flight, the power of steering afforded by the long tail, its vigilant industrious rapacity, and the characteristic erectness of its attitude when perched or engaged with its prey. A stray specimen, said to have been shot in Perthshire, is preserved in the Edinburgh Museum. The Australian Goshawk (*A. novæ hollandiæ*), sometimes called a white eagle, is remarkable in being 'apparently a permanent albino.'

Goshen, that part of ancient Egypt which Pharaoh presented to the kindred of Joseph when they came to sojourn in that country, appears to have lain between the eastern delta of the Nile and the Isthmus of Suez, as far south as the modern Ismailia. The district is generally supposed to have lain round about the Egyptian Kesem (Goshen is *Gesem* in the Septuagint), a name preserved in the classical Phacusa (Pa-Kesem), now Fakoos, about 45 miles S. of Damietta. But in 1885–87 M. Naville tried to prove that Goshen is represented by Saft-el-Henna, 6 miles E. of Zagazig, in the Wady Tumilât. See the *Fourth Memoir of the Egypt Exploration Fund* (1888). The LAND OF GOSHEN was the name given to a part of the Barolong country in Bechuanaland, South Africa, which became in 1884 the seat of a mushroom Boer republic, founded by the marauders who had supported Moshette, the rival of Montsioa in his contest for the headship of the Barolongs. It was, along with the rest of Bechuanaland, declared to be under British protection in September 1885.

Goslar, an ancient town of Hanover, situated on the north slope of the Harz Mountains, 27 miles SE. of Hildesheim. At one time a free imperial city, and the residence of the emperors, it has several noteworthy old buildings, as the tower called the 'Zwinger,' with walls 23 feet thick; the Late Romanesque church Neuwerk, of the 12th century, and the Frankenberger church (1108, restored 1880), both with ancient frescoes; the emperor's house, built in 1050 by Henry III., the dwelling-house of the emperors till the middle of the 13th century, the meeting-place of more than a score of imperial diets, restored in 1867–80, and adorned with frescoes by Wislicenus; the town-house, built in 1136–84; and the Kaiserworth, an old building containing statues of eight emperors. To the south of the town is the Rammelsberg, a mountain formerly very rich in silver, gold, copper, lead, sulphur, and green vitriol (sulphate of iron). The mines have been worked since 968, and are still in operation. Goslar was founded by Henry I. in 920. About 1350 it joined the Hanseatic League. Its ancient prosperity began to depart from it in the middle of the 16th century; and it suffered severely from the Swedes in the Thirty Years' War. In 1802 it ceased to be a free imperial town and fell to Prussia, to whom it again returned in 1866, after having in the meantime belonged to Westphalia (from 1807) and Hanover (from 1816). Here were born Henry IV. and Marshal Saxe. The Wordsworths were here in 1798. Pop. (1875) 9838; (1895) 18,966. See works by Mithoff (1874) and Wolfstieg (1885).

Gospellers, a word used with three different designations. (1) A term applied by the Roman Catholics to those Reformers who taught the people the words of Scripture in their own vulgar tongue, as Wyclif and his followers.—(2) A class of Antinomians, about the period of the Reformation, who drew 'strange inferences' from the doctrine

of predestination.—(3) The priest who reads the Gospel in the communion service of the Church of England, standing on the north side of the altar.

Gospels. The word *euaggelion*, which in classical Greek originally meant 'the reward for good news' (*Odyssey*, xiv. 152; comp. 2 Sam. iv. 10, LXX.), but afterwards simply 'good news' (Plutarch, Lucian, Appian), has from Anglo-Saxon times been rendered by the word *Gospel* (Godspell—i.e. story of God [Christ]). In the New Testament it is always used in the singular, and means 'the good news of the kingdom' as proclaimed by Christ and his apostles. Perhaps, however, in Mark i. 1 there is some trace of the technical sense, as denoting a written narrative of the life and utterances of Jesus, which it had fully acquired by the end of the 2d century (Justin Martyr, *Apol. I.* 66: 'the memoirs of the apostles . . . which are called gospels'). The gradual rise of the historical portion of the New Testament (belonging for the most part to a later period than the Epistles, which are the earliest extant documents of Christianity) has already been briefly traced in the article BIBLE (Vol. II. p. 124), where also the fact of the fixation of the four-fold gospel canon before the close of the 2d century has been stated; see also separate articles on MATTHEW, MARK, LUKE, and JOHN. Here it is enough to say that, since the canon was ecclesiastically settled, it has been the unvarying belief of the church in all its branches that these four gospels are to be received as clothed with apostolic authority—Matthew and John as written by apostles, Mark and Luke as written by companions of apostles.

Of the four, that of John is distinguished by peculiarities which give it a unique place among the New Testament writings, and will most conveniently be treated in the separate article. The first three, on the other hand, have very much in common; in fact, they present such a similarity in matter and form that they readily admit of being brought under one and the same 'combined view' or 'synopsis,' from which circumstance they have since the time of Griesbach (who coined the phrase) been commonly designated the 'synoptical' gospels (see the *Harmonies*, such as Tischendorf's *Synopsis Evangelica*). The resemblance is both in substance and in language. (1) They give the same general outline of the life of Jesus, and to a large extent select the same incidents for detailed treatment. Thus, they relate, on the whole, the same miracles, and preserve the same discourses. They are silent also on the same points; two, for example, give the woe pronounced upon Chorazin and Bethsaida, but no one of the three has anything precise to say about the occasion that called it forth. Various attempts have been made to represent in tabular and graphic form the amount of material coincidence between the synoptics; but it is probably impossible to do so with absolute exactness. The following estimate, however, the result of a recent somewhat careful examination, may be taken as approximately representing the facts. Of a total of 1071 verses, Matthew has 387 in common with Mark and Luke, 130 in common with Mark, 184 in common with Luke, and 370 peculiar to himself. Of Mark's 662 verses, 406 are common to all three synoptists, 145 common to Mark and Matthew, 60 common to Mark and Luke, and 51 (on a liberal estimate) peculiar to himself. Luke out of 1151 verses shares 390 with Matthew and Mark, 176 with Matthew, 41 with Mark, and has 544 peculiar to himself. (2) They often agree in a remarkable manner in the order in which they give the events they relate, even where the events themselves are only loosely connected; thus, in Matt. ix., Mark ii., and Luke v., the miraculous healing of the paralytic, Matthew's call and feast, the discourse on fasting, follow one another; in two gospels the last-mentioned discourse is immediately followed by the incident in the cornfield, which again, in all three, is followed by the healing of the withered hand. In Matthew and Mark the death of the Baptist is introduced at the same point and in the same way, but out of its chronological order. For full discussion of these and other instances reference must be made to the text-books. (3) In many instances they use identical language. This circumstance would be striking enough even if it were observable only in cases where discourses are reported, when it is remembered that these discourses were almost certainly spoken in Aramaic; but its significance is vastly increased when it occurs in narrative passages (Matt. xiv. 19, 20; Mark, vi. 41, 42; Luke, ix. 16, 17; Matt. xvii. 5; Mark, ix. 7; Luke, ix. 35; Matt. ix. 1–8; Mark, ii. 1–12; Luke, v. 17–20—where observe the parenthesis common to all three, 'then saith he to the sick of the palsy'), when it is shown in the use of rare words or expressions, or when all coincide in quoting the Old Testament in a way that differs both from the Hebrew and the Septuagint text.

It is only in modern times that such phenomena as these in the synoptic gospels have attracted serious attention or received critical study. Doubtless they had been often noticed before, but the fact of so large a degree of coincidence was not felt to be at all surprising. All three gospels were held to be first-hand narratives, and primarily all by the same author, the inspiring spirit of God. The resemblance, therefore, was only what might have been expected. Were further explanation pressed for, it was enough to suggest that Mark had copied from Matthew, and Luke had access to both, and this assumed dependence of the later on the earlier evangelist was not felt to affect in any way their importance as really independent, because immediately inspired. More embarrassing were their apparent divergences and even seeming contradictions in narrating what purported to be the same events (e.g. the resurrection and the post-resurrection appearances of Jesus), and their discrepancies of language in relating what seemed to be the same discourses. The reconciliation of these discrepancies and divergences (which were held to be apparent only) was the object of numerous compilers of 'Gospel Harmonies.'

The so-called 'synoptical problem' took shape in Germany towards the close of the 18th century. The discussion began in a refutation by Koppe (*Marcus non Epitomator Matthaei*, 1782) of the traditionally received view, first started by Augustine, that Mark in writing his gospel had merely followed Matthew and abridged him. Important contributions towards the advancement of the question were made in succeeding decades by such men as Lessing, Eichhorn, Griesbach, Schleiermacher, Gieseler, De Wette, Lachmann, Baur, Ewald, Bleek, Ritschl, and others too numerous to mention. In the course of the investigation three broad lines of explanation were attempted. (1) The 'Benutzungs-hypothese,' or borrowing hypothesis, sought to explain the facts by supposing that the second evangelist in order of time (whoever he was) borrowed from the first, and that the third borrowed from either or both of his predecessors. Of this theory numerous forms are logically and mathematically conceivable, and almost all of these have in the course of a century's discussion found able advocates. Perhaps the most popular form has been the 'combination' theory—that Mark is a combination of Matthew and Luke. (2) The 'Ur-evangeliums-hypothese' sought to establish the existence of a primitive written gospel, no longer extant, to which, however, all the evangelists had

access, and of which they each made independent use. (3) The 'tradition hypothesis' was that each evangelist drew his matter independently of the others from an oral apostolic tradition which had become stereotyped.

The result of the discussion has been to make it plain that no one of these theories is by itself sufficient to cover all the facts of the case. The borrowing hypothesis may account for the coincidences, but it leaves the discrepancies unexplained and inexplicable. The same remark applies to the assumption of a primitive gospel or gospels; it has been found necessary by its advocates to assume a multiplicity of lost documents in a manner that raises difficulties, historical and other, quite as great as those which it seeks to remove. The oral tradition theory, again, might serve to account for the discrepancies, but when it is sought to explain the immense amount of coincidence by means of it, the improbability of a stereotype tradition of such mass, confining itself so closely to the same incidents, told in so nearly the same order and in language so little varying, is seen to be very great. But, on the other hand, it is now more or less generally admitted that all three theories contained important elements of truth. (1) In connection with the oral tradition hypothesis it seems tolerably clear that for at least a generation after the death of Christ no important attempt was made to commit to writing any record, however brief, of the leading facts of his life or the main elements of his preaching. This was no doubt partly due to the widespread belief that his second coming and the end of the world were close at hand. The epistles were, as has already been said, the earliest literary productions of Christianity, and these were all called forth by occasions much more definite than any that had as yet presented themselves for writing memoirs of Christ. But the life and words of Christ were the continual subject of the preaching and catechising of the apostles and their converts, a subject they naturally expounded in connection with the Old Testament scriptures. These he had perfectly and completely fulfilled, and Christ was therefore sought in the Old Testament prophecies in a way that made the early Christians feel little need of a written gospel. That this traditional preaching and catechising would tend to become stereotyped within each apostolic circle is manifest; but that it was also capable of taking different forms in different circles is shown (to take obvious examples) by the want of correspondence between the narratives of the nativity and of the resurrection as given in Matthew and Luke respectively. (2) As regards a primitive gospel (or Ur-evangelium, as Eichhorn first called it), specialists are becoming more and more at one in recognising two relatively primitive documents embodied wholly or in part in the existing synoptists. These consist (*a*) in the gospel according to Mark, or an earlier draft thereof; (*b*) in a so-called 'logia' document, composed mainly of sayings and discourses of the Lord—a document which was largely drawn upon by the authors of the first and third gospels for much of what they have in common with each other apart from Mark. The reasons for abandoning the ancient view of Mark's dependence on Matthew, and for now regarding his as the earliest of our existing gospels, depend largely on considerations as to his language, style, and general point of view which cannot be even indicated here, nor does space allow mention to be made of the various minute points which have led many acute scholars to distinguish between an original Mark (Ur-Marcus) and the present form of the second gospel. The designation of the 'logia' document is taken from a much discussed fragment of a very early author, Papias, preserved by Eusebius, to the effect that 'Matthew composed *ta logia* [the oracles, or the discourses of our Lord] in the Hebrew [i.e. Jewish-Aramaic] dialect, and each one interpreted them as he could.' Schleiermacher was the first to point out the importance of this passage in its possible bearings on criticism. (3) The borrowing hypothesis, in the sense that the authors of the first and third gospels knew and very freely used the earlier work of Mark, is by no means a violent one, and seems in many cases to afford the true explanation of the facts.

The drift of current opinion among specialists may perhaps be stated somewhat as follows: When after the lapse of a generation or so it began to be seen that probably the end of all things was not yet quite at hand, and that in all likelihood the church had still before her a prolonged period of work in the present world, it was felt to be a fitting thing that the most important utterances of the Lord, which the apostles had been in the habit of quoting as supremely authoritative for all Christians, should be preserved from the risk of perversion, interpolation, or oblivion. Thus came to be written down, by some apostolic man—very likely by the apostle Matthew himself, a practised scribe—a collection of discourses, parables, predictions, and aphorisms, not improbably in somewhat loose connection, yet at the same time not without some incidental notice of the circumstances which occasioned a given utterance, or some notes of the dialogue which led up to the weighty aphorism. This collection was (as has been seen) written in Aramaic. About the same time, Mark, the 'interpreter' of Peter, as ancient tradition calls him, was arranging in Greek his fragmentary recollections or memoirs of what he had heard Peter tell of the incidents of the period of his own personal converse with Jesus. These he would not scruple to supplement with matter drawn from other sources, so long as he knew it to be trustworthy. Both the above documents obtained wide currency, the former was translated into Greek more or less inadequately, the two were seen to be mutually complementary, and it was inevitable that an attempt should be made to combine them. This was successfully done by the author of the first gospel, a writer in Greek, who had in view in the first instance Jewish Christians, and sought to bring into all possible clearness the organic development of Christianity out of the Old Testament dispensation of symbol, prophecy, and promise. After the destruction of Jerusalem, when Rome had become one of the most important centres of Christianity, there was edited in that city the present form of the second gospel, specially adapted for the apprehension and acceptance of Gentile Christians. At a somewhat later date, and possibly in Rome also, was compiled the third gospel in dependence chiefly on the 'logia' document and on Mark, but not without some knowledge of the first gospel, and with important additions from oral or written sources which cannot now be traced, but which probably represented a Judæan tradition.

Thus it appears that each of the three theories enumerated above has something real to contribute by way of explanation of the origin of the synoptic gospels. Primitive documents are embodied in them; they contain an element of ancient oral tradition; and they are not independent one of another. But no one of them is a primary document in the sense of having been written in its present form from direct personal knowledge; and it is obvious that each succeeding evangelist, in availing himself of the labours of his predecessor, did so with a feeling of perfect freedom, not claiming for himself, nor according to his fellow, nor

expecting for either from the church any title to authority as infallible.

Harmonies of the Gospels. Compilations of this nature, designed to facilitate comparison and mutual illustration of the different narratives, and to bring out their essential agreement and consistency in seeming divergence, began to be made at an early date. The earliest known is the *Diatessaron* of Tatian (q.v.). Jerome also makes allusion to the work of a certain Theophilus, Bishop of Antioch, toward the close of the 2d century, who had left a monument of his ingenuity by 'fitting together into one whole the things said by the four evangelists.' Eusebius tells us that in the middle of the 3d century a certain Ammonius of Alexandria also constructed a diatessaron, taking Matthew as his basis, and placing side by side with him the parallel passages in the other three gospels. This work suggested to Eusebius himself the plan of his own *Sections and Canons*. In this each gospel is divided separately into sections which are numbered continuously, and, further, there is a table of ten canons each containing a list of passages. The first canon, in four columns, exhibits all the passages which are common to the four gospels; the second, third, and fourth, in three columns, show the passages which are found in any three; the fifth, sixth, seventh, eighth, and ninth, those which are common to any two; and the tenth, in four separate lists, the passages peculiar to a single evangelist. This work of Eusebius, which was afterwards adapted to the Vulgate by Jerome, continued to be used as a key to the concordance of the gospels, down to the 16th century. Of post-Reformation harmonies, the earliest is the *Harmonia Evangelica* of Osiander (1537), whose doctrine of inspiration led him to believe that each evangelist must have written in strict chronological order, and that therefore, wherever there is the slightest divergence as to time, place, or circumstance between any two evangelists in any given narrative, it is necessary to assume the events thus differently related to have been distinct. On these principles he is compelled to make out that Peter denied his Lord nine times. Calvin's *Harmonia ex tribus Evangelistis Compositia* (1553) represents a much more moderate view. The number of works bearing the title of *Harmonies* or *Synopses* that have appeared during the last three centuries is very great. The best and most popular of them—such as those of Clericus (1700), Macknight (1756), Griesbach (1776), Robinson (1845) Wieseler (1843), Anger (1852), Stroud (1853)—are enumerated by Tischendorf in his own *Synopsis Evangelica*, the latest and most convenient of them all (5th ed. 1884).

Literature.—For the older literature on the synoptic gospels, reference must be made to the handbooks of Biblical Introduction and Church History, and to the more recent commentaries. Among these last that of Alford in his *Greek Testament* (7th ed. 1874–77) retains an honourable place. See also the *Speaker's Commentary*. Of translations from the German, the commentaries of Meyer and Lange claim special mention; of the former, which is the less homiletical and more scientific of the two, the latest (7th) German edition is by B. Weiss (1883–85). Keil's Commentary on Matthew appeared in 1877, and that on Mark and Luke in 1879. In the new *Hand-Commentar zum Neuen Testament* the synoptics are ably treated by H. J. Holtzmann (1889). Ewald's *Die drei ersten Evangelien übersetzt u. erklärt* (1871) is still of value. See too Reuss, *Histoire Évangelique* (1876); and compare the bibliographies under Bible and Jesus. For the apocryphal Gospels, see Apocrypha.

On the synoptical problem the fullest and latest statements are to be found in Holtzmann, *Einleitung in das Neue Testament* (2d ed. 1886), and B. Weiss, *Einl. in d. Neue Test.* (2d ed. 1889). The latter has been translated into English, *A Manual of Introduction to the New Testament* (1887). Both these writers recognise a 'logia' document, and the priority of Mark to both the first and the third canonical gospel. Weiss, however, thinks that the logia document contained a very considerable number of incidents also, and that Mark had access to it. The fullest discussions by English scholars are those of Dr E. A. Abbott in the art. 'Gospels' in vol. x. of *Ency. Brit.* (1880), and by Professor Salmon, *Historical Introduction to the Books of the New Testament* (4th ed. 1889). Dr Abbott seeks to disentangle the original 'triple' tradition borne witness to by the three synoptics; he finds that Mark is of earlier date than Matthew, and contains the earliest Greek tradition, itself a translation of the very early Aramaic tradition. Dr Salmon argues for a form of the Ur-evangelium hypothesis; he thinks the theory of a common Greek original is required by the verbal coincidences, and by the common citations of the Old Testament. Mark's gospel represents the original source most fully, but was probably latest in publication, and certainly not copied either by Matthew or by Luke. Dr Westcott in his *Introduction to the Study of the Gospels* (1851; 7th ed. 1888), which unfortunately has not been brought down to date, argues for the oral hypothesis. This theory is also that of Alford. Of the borrowing hypothesis the latest and ablest exponent is Dr Pfleiderer, who in his *Urchristenthum* (1887) shows the priority of Mark, but thinks that Matthew depended chiefly on Luke. For detailed study of the relations of the synoptics, Rushbrooke's *Synopticon* (1880), which gives all the textual facts with graphic completeness, may be characterised as indispensable. Compare also Rushbrooke and Abbott's little manual entitled *Common Tradition of the Synoptical Gospels in the Text of the Revised Version* (1884).

Gosport ('God's port'), a market-town and seaport of England, in the county of Hants, stands on the western shore of Portsmouth harbour, and directly opposite Portsmouth, with which it is connected by a floating bridge. Here are an extensive iron-foundry for the manufacture of anchors and chain-cables, naval powder-magazines, several barracks, the Royal Clarence victualling yard, which contains a brewery, a biscuit-baking establishment worked entirely by steam, and numerous storehouses, and Haslar Hospital (q.v.). The town has also some sail-making and yacht-building, and considerable coasting trade. Pop. (1851) 7414; (1891, with Alverstoke) 25,452.

Gossamer, a light filamentous substance which often fills the atmosphere to a remarkable degree during fine weather in the latter part of autumn, or is spread over the whole face of the ground, stretching from leaf to leaf, and from plant to plant, loaded with entangled dew-drops, which glisten and sparkle in the sunshine. Various opinions were formerly entertained concerning the nature and origin of gossamer, but it is now sufficiently ascertained to be produced by small spiders, not, however, by any single species, but by several, not improbably many, species; whilst it is also said to be produced by young and not by mature spiders, a circumstance which, if placed beyond doubt, would help to account for its appearance at a particular season of the year. The production of gossamer by spiders was first demonstrated by the observations of Dr Hulse and Dr Lister in the 17th century; but these observations did not for a long time meet with due regard and credit, particularly amongst the naturalists of continental Europe. It is not yet well known if the gossamer spread over the surface of the earth is produced by the same species of spider which produces that seen floating in the air, or falling as if from the clouds. Why gossamer threads or webs are produced by the spiders at all is also a question not very easily answered. That they are meant merely for entangling insect prey does not seem probable; the extreme eagerness which some of the small spiders known to produce them show for water to drink has led to the supposition that the dew-drops which collect on them may be one of the objects of the formation of those on the surface of the ground, whilst it has been also supposed that they may afford a more rapid and convenient mode of transit from place to place than the employment of the legs of the animal. As to the gossamers in the air, conjecture is still more at a loss. They are certainly not accidentally wafted up from the ground, as might be supposed; the spiders which produce them are wafted up along with them; but

whether for the mere enjoyment of an aerial excursion, or in order to shift from place to place, is not clear, although the latter supposition is, on the whole, the most probable. The threads of gossamer are so delicate that a single one cannot be seen unless the sun shines on it; but, being driven about by the wind, they often become beaten together into thicker threads and flakes. They are often to be felt on the face when they are scarcely visible. The spiders which produce these threads shoot them out from their spinnerets, a viscid fluid being ejected with great force, which presently becomes a thread; sometimes several such threads are produced at once in a radiating form, and these, being caught by the ascending current of heated air, are borne upwards, the spider along with them. It has been said that the spider has even some power of guiding in the air the web by which it is wafted up (see SPIDER). The etymology has been much disputed. According to Skeat, *gossamer*, the Middle English *gossomer*, is *goose summer*, the *summer* meaning *summer-film*. Another derivation is from *God* and *summer*, the latter word being from the Romance *samarra*, 'a skirt,' from the legend that gossamer is shreds of the Virgin Mary's shroud, which she cast away when she was taken up to heaven.

Gossan, a mining term for oxide of iron and quartz. See IRON.

Gosse, PHILIP HENRY, naturalist, was born at Worcester, 10th April 1810, and brought up at Poole. In 1827 he went to Newfoundland as a clerk, and was afterwards in turns farmer in Canada, schoolmaster in Alabama, and professional naturalist in Jamaica. Returning to England, he published in 1840 the *Canadian Naturalist*, and after another stay in the West Indies settled in England to a busy life of letters. His early experiences and observations supplied the material for his popular books, the richly illustrated *Birds of Jamaica* (1851) and *A Naturalist's Sojourn in Jamaica* (1851). His *Naturalist's Ramble on the Devonshire Coast* (1853), *Aquarium* (1854), and *Manual of Marine Zoology* (1855–56) inspired Charles Kingsley's *Glaucus*, and opened up a new branch of science to Englishmen. Gosse was elected a Fellow of the Royal Society in 1856, and over sixty monographs in its *Proceedings* are from his pen. His best-known work, the *Romance of Natural History*, appeared in 1860–62. Later and more severely scientific works were his *Actinologia Britannica* (1860) and the *Prehensile Armature of the Papilionidæ* (1885). In 1886 he placed in the hands of Dr C. T. Hudson the notes and drawings of a lifetime on the microscopic study of the Rotifera. Mr Gosse spent the last thirty years of his life in a retired South Devon village, and died 23d August 1888. EDMUND WILLIAM GOSSE, his only son, was born in London, September 21, 1849, was educated in Devonshire, and became at eighteen an assistant-librarian at the British Museum, in 1875 translator to the Board of Trade. He travelled in Scandinavia and Holland, and made himself master of the languages of these countries. In 1884 he succeeded Mr Leslie Stephen as Clark lecturer in English literature at Trinity College, Cambridge, a post from which he retired in 1889, having four years before received the honorary degree of M.A. from the university. During 1884–85 he lectured in Boston, at Harvard and Yale colleges, and in Baltimore and New York. Mr Gosse has tried various forms of verse, and possesses many of the qualities of the genuine poet. Among his writings in verse are *Madrigals, Songs, and Sonnets* (1870); *On Viol and Flute*, lyrical poems (1873); *King Erik*, a tragedy (1876); *The Unknown Lover*, a drama (1878); *New Poems* (1879); and *Firdausi in Exile, and other Poems* (1885). His chief writings in prose are in the field of literary criticism: *Northern Studies*, a series of essays on Scandinavian and Dutch literature (1879); *Gray*, in 'English Men of Letters' (1882); *Seventeenth-century Studies*, on Lodge, Webster, Rowlands, Herrick, Crashaw, Cowley, Etheredge, and Otway (1883); *From Shakespeare to Pope* (1885); *Life of Congreve* (1888); *History of Eighteenth Century Literature* (1889); *Critical Kit-Kats* (1896); and a *History of Modern English Literature* (1897). Besides these he contributed many critical essays towards *English Poets* (1880–81), edited *English Odes* (1881), and a faultless complete edition of Gray (1884). He published a Life of his father in 1890, and contributed the article POETRY to this Encyclopædia. The *Secret of Narcisse*, a prose tale, appeared in 1892.

Got, FRANÇOIS JULES EDMOND, actor, was born at Lignerolles in 1822, entered the Conservatoire in 1841, and in 1844 made his début. He was soon one of the finest comedians of his day. From 1850 to 1866 he was a member of the Comédie Française, playing with success such parts as Figaro in the older comedy, but in general regarded as the mainstay of the new dramatic school. In 1866, with the emperor's special permission, he appeared at the Odeon as André Lagarde in Augier's *Contagion*, and organised a company to carry the play through France. He has repeatedly played in London. In 1881 he was decorated with the cross of the Legion of Honour. His most finished performances were as Giboyer in Augier's *Effrontés* and *Fils de Giboyer*, and as Bernard in *Les Fourchambault*.

Gotha, a town of Germany, alternately with Coburg the capital of the duchy of Saxe-Coburg-Gotha, stands 31 miles W. by S. of Weimar, on the northern outskirt of the Thuringian Forest, and is a handsome, well-built town, with fine parks. The principal public building is the castle of Friedenstein, built in 1648 on the site of a former one, on a rock 78 feet above the town; it contains a library of 200,000 volumes and 6000 MSS., and a very valuable numismatic collection. The new museum (1878), in the Renaissance style, now harbours the picture-gallery, in which Cranach, Van Eyck, Holbein, Rubens, and Rembrandt are represented; a very excellent cabinet of engravings; a natural history collection; collections of Egyptian, Roman, Greek, and German antiquities; and a Japanese and Chinese museum. A new observatory was built in 1874. Gotha is an active industrial town, the principal manufactures being shoes, fire-engine pipes, sugar, and toys. Gotha sausages have a widespread celebrity. Several hundreds of designers, engravers, printers, and colourers of maps are employed here in the large geographical establishment of Justus Perthes (q.v.), who also publishes the *Almanach* (q.v.) *de Gotha*. Pop. (1875) 22,928; (1890) 29,134. See Beck, *Geschichte der Stadt Gotha* (1870).

Gotha, DUCHY OF. See SAXE-COBURG-GOTHA.

Gotham, TALES OF THE MEN OF, a collection of jests, in which the people of Gotham, a village in Nottinghamshire (7 miles SSW. of Nottingham), are represented as saying and doing the most foolish things. These tales are similar to the *Asteia*, or facetiæ, ascribed, without authority, to the 5th-century Alexandrian philosopher Hierocles. The stories seem to have been first printed about the middle of the 16th century, under the title of *Merrie Tales of the Mad Men of Gotham, gathered together by A. B., of Phisicke Doctour*; but they had been orally current in the time of Henry VI., reference being made to 'the foles of Gotam' in the Towneley miracle-plays, the only known MS. of which was written about that period. The initials 'A. B.' of

the putative compiler were doubtless intended by the printer to signify Andrew Boorde (q.v.), who was popularly regarded as 'a fellow of infinite jest.' But there is no reason to suppose that Boorde had any hand in the work, his initials being placed on the title-page—as also on that of the *Jests of Scogin*—in order to promote its sale. Long before the men of Gotham were saddled with the unenviable reputation of being typical blockheads similar jests had been told at the expense of the people of Norfolk, as we learn from a curious Latin poem entitled *Descriptio Norfolciensium*, written in the 12th century by a monk of Peterborough, which is printed in Wright's *Early Mysteries and other Latin Poems*. In this 'poem' occurs the familiar jest of the man who was riding on horseback with a sack of meal, and considerately placed the sack on his own shoulders to lighten the horse—a story which reappears in the Gothamite drolleries and in the *Bigarrures* of the *Sieur Gaulard*, by Étienne Tabourot (1549–90), and which is at the present day current in Ceylon.

The Gothamite jest most generally known is that of the attempt of the villagers to hedge in a cuckoo, so that it should 'sing' all the year round. Among other witless exploits they tried to drown an eel that had eaten up all the fish in their pond; they fastened their rents on a hare which they had caught, and sent it off to their landlord; a smith burned down his smithy by thrusting into the thatch a red-hot ploughshare, to destroy a wasp's nest; and twelve of them went a-fishing, and before returning home one counted their number to see whether all were safe, but omitted to include himself, whereupon they weened that one of them was drowned, and were lamenting this misfortune, when a traveller coming up, and learning the cause of their distress, soon set their minds at ease. Such jests are—*mutatis mutandis*—common to almost all the races of mankind, from Iceland to Japan, from Ceylon to the West Highlands of Scotland; and it is curious to find that the inhabitants of some particular district or village are popularly held up as arrant simpletons. In Britain, besides the men of Gotham, the 'carles of Austwick' in Yorkshire, the villagers near Marlborough Downs in Wiltshire, the 'gowks of Gordon' in Berwickshire, and the folk of Assynt in Sutherlandshire; in Germany, the Schildburgers; in Holland, the people of Kampen; in Belgium, the townsfolk of Dinant; in France, the inhabitants of Saint-Maixent, are credited with all sorts of absurdities. The citizens of Abdera, Sidonia, &c. were the noodles of the ancient Greeks, and not a few of the so-called jests of Hierocles reappear in our early English collections of facetiæ, with a blundering Welshman or Frenchman in place of the pedant of the *Asteia*, and in more recent compilations—'Joe Miller' and its congeners—the conventional Irishman or Highlander. The similarity of simpleton stories in countries far apart at once suggests the question of their origin and diffusion, as in the case of popular tales generally. No doubt in many instances they sprang up independently, for human nature is everywhere much alike; but it is equally certain that a considerable number have been borrowed by one people from another, sometimes imported orally, most frequently taken from written sources. But however widely modern scholars may differ in opinion regarding the genealogy of popular fictions, their virtual identity among divers races is an interesting evidence of the kinship of man.

The *Tales of the Mad Men of Gotham* continued to be issued in chap-book form down to the second decade of the 19th century. The first reprint of the original work was made in 1840, with an introduction by Mr J. O. Halliwell. The *Tales* were also printed in W. C. Hazlitt's *Shakespeare Jest-books* (1864); in John Ashton's *Chap-books of the Eighteenth Century* (1882); and in R. H. Cunningham's *Amusing Prose Chap-books* (1889). For a compendious collection of simpleton stories—of which the Gothamite tales form but a trifling part—see W. A. Clouston's *Book of Noodles* (Lond. 1888), which will be found to contain references to all the important books dealing with the subject, oriental and other. See also W. J. Thoms, in the *Foreign Quarterly Review* (1837, No. 40); and *Deutscher Volkshumor*, by Moritz Busch (Berlin, 1877).

Gothard. See St Gotthard.

Gothenburg (Swed. *Göteborg*), next to Stockholm the most important town of Sweden, stands at the mouth of the Göta, in 57° 42′ N. lat. and 11° 58′ E. long. Although originally founded by Gustavus Adolphus in 1618–21, the town, in consequence of numerous fires, is quite modern—regularly built and clean, with several canals, crossed by numerous bridges. The harbour is excellent, and seldom obstructed by ice. The few buildings which deserve special mention are the exchange, cathedral, and town-hall. There is a museum (art, zoology, industry) besides a fine garden belonging to the Horticultural Society. The more important industries embrace shipbuilding, iron-working, sugar-refining, the manufacture of matches, paper, wood pulp, and porter, and herring-fishing. The exports consist principally of iron, timber, grain, butter, matches, paper, wood pulp, zinc ore, hides; the imports of coal, iron, salt, flour, grain, machinery, oils, rice, wines and spirits, and sugar, the annual value of imports and exports being each about 3 millions. The port is entered and cleared by about 5070 vessels of 1,815,380 tons burden every year. The commercial importance of Gothenburg dates from the Continental blockade of 1806, when it became the chief British depôt in northern Europe. The town has given its name to the Gothenburg Licensing System, which originated here in 1865. All the wine and spirit shops are kept by a company licensed by the town authorities, and are conducted by salaried managers; all profits remaining after the company has been allowed five per cent on its capital go into the town treasury. See Licensing Laws. Pop. (1877) 71,707; (1888) 99,647; (1895) 111,250.

Gothic Architecture. Under this title are comprised the various styles of architecture which prevailed in western Europe from the middle of the 12th century till the revival of classic architecture in the 16th century. The term *Gothic* was at first bestowed by the Renaissance architects on the medieval styles as a term of reproach. This epithet they applied to every kind of medieval art which had existed from the decline of the classic taste till its revival, all other styles being by them considered as *barbarous* and *Gothic*. The name has now, however, become generally adopted, and has outlived the reproach at first implied in it. It has also become limited and defined in its application. During the 19th century the arts of the middle ages have been attentively studied, and their origin and history carefully traced; and as the knowledge of these styles has increased, a feeling of admiration has succeeded to that of contempt, and Gothic now ranks as one of the noblest and completest styles of architecture.

Origin.—The origin of Gothic architecture has given rise to many very ingenious speculations. It has been said that the style was copied directly from nature; that the pointed arches and ribs of the vaults were imitated from the overarching branches of trees; and that the stems of an avenue were the originals of the pillars of the Gothic aisles. Others have strenuously maintained that the invention of the pointed arch was a mere accident, arising from this form having been observed in the interlacing of the circular arches of a Norman

arcade. It has also been stated that the style was imported from the East during the Crusades, and that the mediæval architects had but little to do with its origin. More careful study of the Gothic buildings which remain to us has dispelled these fanciful ideas, and settled the origin and progress of the art on historical as well as internal evidence.

To trace Gothic up to its primary elements we have to go far back in the world's history. Many diverse styles have prevailed at different epochs and in different countries, and the later styles have invariably been influenced by those which preceded them. All the various styles of architecture may, however, be classed under two groups, the representatives of which are Greek architecture and Gothic architecture. These are the two typical styles, and in them are contained and exhibited in a very pure form the elements from which all other styles are produced. This is true in the same sense as it is also true that all things in nature are derived from a few primary elements. But as there are many varieties in nature, so there are many developments of the two typical forms of architecture, all of which may be classed as styles.

The principles which underlie the two great divisions of architecture are structural in character; for the decorative features of all true styles are founded on the construction. The first of these divisions is distinguished by the employment of the horizontal beam as the method of spanning openings; while in the other the arch is the means used for the same purpose. All other specific differences of style are subordinate to these leading factors. Of these divisions Greek architecture is accepted as the highest type of the *trabeated* style—i.e. the style whose principal feature is the straight lintel; Gothic, as the type of *arcuated* architecture, in which the voids are spanned by arches. These typical forms present many varieties, Roman Architecture (q.v.) being the transitional form between them. The trabeate form of construction was common to the primitive inhabitants both of Greece and Italy. The early Romans' buildings were therefore trabeate in principle, and their exteriors were decorated with columns crowned by straight architraves and cornices. But in course of time they gradually introduced inside these, and hidden from view, a real construction with arches and vaults. These constructional elements had long been in use amongst the Etruscans in Italy for drains, bridges, gateways, and other utilitarian purposes, and by slow degrees they obtained recognition as architectural features in the elevations. Their use gradually extended, especially in the construction of interiors, and by means of vaults the Romans were able to roof in large areas without encumbering the floor with pillars. This was found to be a very advantageous and lasting system of construction, and under the empire was carried out in many important examples, as, for instance, in the baths of Caracalla and Diocletian, the Basilica of Maxentius, &c. In their works of public utility, where use, not decoration, was the chief object, the Romans always adopted the arch as the fittest mode of construction—as in their Aqueducts (q.v.), bridges, &c. The arch thus came gradually more and more into use; and about the time when the barbarians first overran the provinces the arcuated form of construction was universal, and some attempts had been made to conform the trabeate decoration to the circular arches by bending the architrave round the curve—as in the palace of Diocletian at Spalato in Dalmatia.

To the Romans, therefore, is due the introduction of an arcuated construction with a well-developed internal, and a partially-developed external, decoration. The early Christians adopted their forms of construction and decoration from the Romans. They were also indebted to them for the plans of the buildings which became the types of the Christian sacred edifices during the middle ages. There was no new style created by the early Christians. Their buildings were all founded on Roman design till about the 10th century. The Basilica (q.v.), or Roman court-house and market-place, was found to be admirably adapted for early Christian worship, and the general opinion has hitherto been that the church was derived from the basilica. But this view has been combated by Professor Baldwin Brown in his work *From Schola to Cathedral* (1886), in which he derives the form of the nave from that of the *scholæ*, or halls of meeting of guilds permitted under the empire, amongst which the burial societies of the Christians were numerous; whilst he attributes the apse, a very prominent feature in early churches, to the memorial cellæ erected by pagans and Christians alike in the cemeteries, and afterwards introduced along with the bodies of saints into the churches. There can be no doubt, however, that the circular temples were the prototypes of the Christian Baptisteries (q.v.) which usually accompanied the basilicas. In erecting their buildings the Christians not only adopted the plans and mode of construction, but used the actual materials of the buildings of the Romans, many of which had been destroyed by the barbarians. Where such materials were abundant—as in Rome and central Italy—the early Christian architecture very closely resembled that of the Roman buildings which had preceded it. But in more remote districts the builders, finding no ready-made materials at hand, had to design and prepare new ones. In doing so they followed as closely as they could the Roman originals, but their buildings partook more of the constructional than the decorative elements of Roman architecture. The Roman ornament thus dropped out of use; and when, in process of time, decoration was desired, each new people followed its own ideas. The traditional Roman decoration thus became to a great extent lost, and new styles developed. In this way the Teutonic tribes introduced into their architecture the scenes of hunting and fighting in which they rejoiced, the ornament showing the figures of animals and men intermixed with the acanthus leaves and other foliage of Roman design.

The different forms of vaulting developed by the Romans were followed throughout the empire during its decline, but gradually special forms were adopted in the different provinces. Thus the architects of the East preferred the *dome* as the distinguishing feature of their style, and those of the West retained the plain tunnel-vault. The former style is called Byzantine (q.v.), and has been the type of all Eastern mediæval architecture; and the latter Romanesque (q.v.), and has been the origin of all the mediæval architecture of western Europe. This Romanesque style varied much in different provinces—being more Roman in type in central Italy and Provence where Roman examples abounded, and more Gothic on the Rhine and in Switzerland and Lombardy where the Teutonic elements prevailed. Roman forms were still adhered to in the Gothic provinces as late as the 9th century, when we find Charlemagne erecting his great mausoleum at Aix in imitation of San Vitale at Ravenna, which was itself derived from a Roman original.

History. The various modifications in different countries all contributed to the general progress of the art; but, as might be expected, it is to the banks of the Rhine where the successors of Charlemagne chiefly dwelt that we must look for the first step in the development of Gothic architecture.

The following short sketch of the history of the vaulting will show how this occurred.

The Roman basilicas, and, like them, the early Christian churches (for ground-plan see the article BASILICA), were divided into a central nave and two or four side-aisles, the former separated from the latter by one or two rows of columns on each side. These columns carried arches on which rested the side-walls of the nave, which were carried sufficiently high to clear the roofs of the side-aisles, and admit windows to light the central nave. This row of windows afterwards became the Gothic Clerestory (q.v.). At the east end of the nave was a great arch leading into an open space, in the centre of which was the apse. The latter was semicircular in plan, and was usually roofed with a vault in the form of a semi-dome. This feature was also afterwards more fully developed, and surrounded with radiating chapels in Gothic churches. The nave and side-aisles were originally roofed with wood, but, owing to their frequent destruction by fire, it became necessary to cover the churches with a more enduring kind of construction. It was then attempted to introduce vaulting; but the skill of the workmen had degenerated, and many efforts were needed before a system suitable for the requirements of the period and within the capacity of the builders was arrived at. But, as we shall presently see, when the principle of pointed vaulting was once grasped, the development of the style followed with astonishing rapidity. To trace the progress of vaulting from the early simple tunnel-vault copied from the work of the Romans to the fully-developed and magnificent groins of Gothic cathedrals is a most interesting inquiry; and indeed includes the history of the development of Gothic architecture. There is one consideration which will help to explain how the Roman vaults came to be gradually modified and new forms sought out. To the Roman emperors who built the splendid vaults of the baths, and who had a subdued world at command, *materials* and *labour* were of small consideration. They could therefore afford to build in a style which required perfect materials and workmanship. But medieval princes and bishops could obtain neither. To economise these, therefore, the utmost skill and attention were required. It was necessary to avoid those large and expensive materials of which the Romans were so lavish, and to adopt the simplest and easiest forms of construction.

The first vaults tried were simple semicircular tunnel-vaults. It was found that these, besides being very gloomy, required very massive walls to resist their thrust. An attempt was then made to relieve this thrust by *transverse arches* (*a*, *a*, fig. 1) thrown across—at intervals—under the tunnel-vault, to act as strengthening ribs. This idea was

Fig. 1.

also borrowed from Roman precedent. Buttresses with a slight projection were applied outside to abut the transverse arches, and a beam of wood was sometimes introduced at the wall-head from buttress to buttress to assist in opposing the thrust of the vault.

This was the first attempt to concentrate the weight of the vault on single points. In the side-aisles, where the span was small and manageable, the Roman intersecting vaults (*b*, *b*, fig. 1) were used; and as the main roofs with their tunnel-vaulting were found very gloomy and ill lighted, it was considered desirable that similar intersecting vaults should be used to cover them also, so as to admit of the clerestory windows being raised in order to light the vaulting. But how was this to be managed with the inferior materials and workmanship at command? If the transverse arches AB, CD (fig. 2) are semicircular, and the side-arches AC, BD the same—the vault being formed by two intersecting cylinders—then the intersecting groins AD and CB must be elliptical. This

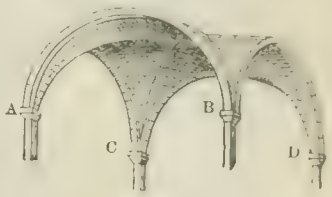


Fig. 2.

was a difficult form of construction: the medieval builders found it easier to construct the groin or diagonal arches of a circular form with radius EA (fig. 3), and to fill in the triangular spaces ABE, &c., with slightly domed vaults. These semicircular edges or groins gradually came to form independent ribs. At first they were only marked by a bead on the angle, but being the chief constructional element of the vaulting they soon came to be distinctly separated from the rest of the vault as independent members with the name of groin ribs, the development of which played so important a part in Gothic vaulting. When the space to be covered was square the above form of vault was found to answer, and each bay of the nave usually included two bays of the side-aisles, as in fig. 4. But this arrangement looked awkward externally, the windows of the clerestory not grouping well with those of the side-aisles. A transverse arch (*a*, *a*, fig. 3) was then introduced, carrying up the design from the nave piers to the vaulting.

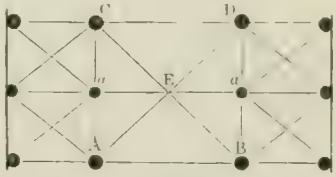

Fig. 3.

This form of vault is called hexapartite. All the above varieties of vaulting were fully developed during the 11th and 12th centuries in the round-arched styles of the Rhine.

In France these forms were also tried; but it was found that the semicircle is not a good form of arch unless loaded on the haunches, many of the churches which were vaulted in this manner during the 11th century having to be buttressed or rebuilt in the 12th and 13th centuries. In Provence (where the Roman influence continued to be strongly felt, owing to the large number of Roman buildings still surviving in the country) the tunnel-vault (fig. 4) was in use probably as early as the 9th or 10th century. But the form of the vault adopted then differed from that of the Romans in being pointed instead of round. The pointed form may have been borrowed from the Moors in Spain, by whom it was used as a decorative feature, but it was undoubtedly adopted in Provence as a simply-constructed method of vaulting. This form of arch was thus probably suggested in the 12th century to the architects of the north of France, who at once saw how well it would overcome the

difficulty of the yielding of the haunches in the semicircular arch. They were thus led to the adoption of the pointed form for their transverse arches *as a structural expedient*, and still retained the semicircular form in the groins. The next question which engaged attention, and the solution of which led to the further use of the pointed arch, was the

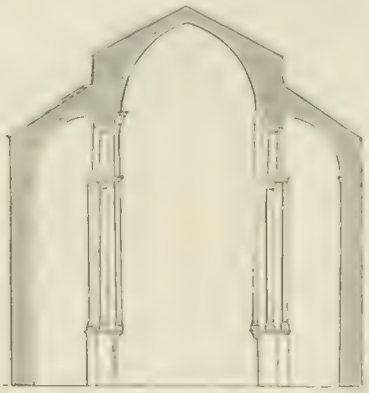

Fig. 4.

vaulting of oblong spaces. This had been tried with semicircular arches, but it was found that with that form the vault would require to be very much domed—the diameter of the arches *c*, *c* (fig. 1) being so much smaller than that of *a*, *a*—whereas by using pointed arches, of different radii, for the transverse and side arches all might be kept to about the same height. This is more fully explained by fig. 5. If AB be the diameter of the transverse arch (*aa*, fig. 1) and AC that of the side arches (*cc*), it is clear that the semicircular side arch ADC cannot reach the height

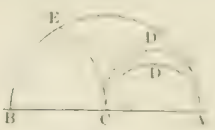

Fig. 5.

Fig. 6.

of the transverse arch AEB, even when stilted as at D'. But in the pointed arch CEB the same diameter rises to very nearly the height of the transverse arch. The pointed arches ACB and A'CB' (fig. 6) show how easily arches of this form, whatever their diameter, can be carried to the same height. By the introduction of this new form of arch the vaulting was strengthened, and the thrust brought to bear steadily on single points.

We have now traced the history of vaulting from the time of the Romans to the 12th century, when the principles of Gothic pointed vaulting were fully developed; and we have dwelt particularly on this subject, because it includes the principles which regulated the whole of the Gothic style. Gothic was not the invention of an individual, but a necessary growth—a gradual development from structural requirement. This is clearly the case with regard to the vaulting, as we have endeavoured to show above, and the same might be proved regarding every member of the style. Thus it might be shown how the ribs became gradually more decided, expressing the part they bore in the support of the roof; how the nave piers or pillars were subdivided by degrees into parts, each shaft bearing on a separate cap a separate member of the vaulting; how the buttresses were developed as they were required to resist the thrust of the groins concentrated on points; and how the flying buttresses were forced upon the Gothic architects much against their will, as a mode of supporting the arches of the roof.

The history of the flying buttress is curious. The thrust of the tunnel-vault was sometimes resisted by half-tunnel-vaults over the side-aisles (see fig. 4). The latter, therefore, required to be high, and a gallery was usually introduced. In the Narthex at Vezelay (fig. 7) we have this gallery with the vaulting used as a counterpoise to that of the central vault. This is a fine example of vaulting in the transition state, that of the gallery resisting the main vault, as in fig. 4, and being at the same time groined.

Fig. 7.

This leaves rather a weak point opposite the transverse arches, to strengthen which the part of the semi-tunnel-vault (fig. 4) opposite the transverse arch is left standing, although the rest is altered by the groining. At Vezelay (fig. 7) this arch timidly shows itself as a small flying buttress above the roof. It is easy to see how this idea would gradually develop itself into the bold 'arc-boutant' of a later date. The galleries were, in later examples, dispensed with to admit of larger clerestory windows, and the flying buttresses were left standing free. The architects finding them indispensable, then turned their attention to render them ornamental. *Pinnacles* may also be shown to owe their origin to their use; they acted as weights to steady the buttresses and piers. We shall, under their separate heads, point out how each element of Gothic architecture was in the strictest sense constructional, the decoration being in harmony with its actual use, or as Pugin has said, 'decorated construction, not constructed decoration.'

The full development of Gothic vaulting, which was the forerunner of the whole style, was first carried out in the royal domain in France about the middle of the 12th century.

The Normans had settled in the north of France more than two centuries before this, and had applied their talents and the fruit of their conquests to the building of splendid temples in honour of their victories. In doing so they followed out the round-arched style, and brought it forward by a great stride towards true Gothic. See NORMAN ARCHITECTURE.

South of the royal domain, in Burgundy, there had existed for centuries great establishments of monks, famous for their architecture. The abbey of Cluny was their central seat, whence they sent out colonies, and built abbeys after the model of the parent one. The style in which they worked was also an advanced Romanesque, but different

from that of the Normans. We have already seen that another school existed in Provence; and in Aquitaine, Auvergne, and Poitou still further varieties of Romanesque were developed.

Between these provinces lay the royal domain. Owing to the weak state of the kingdom, architecture had hitherto made little progress in the Isle of France. About the beginning of the 12th century the monarchy revived, and for the next two centuries the royal domain was governed by wise and powerful monarchs, who succeeded in re-establishing the royal supremacy. A new impulse was thus given to the literature and arts of the country, by which architecture profited largely. From the state of ruin into which the kingdom had fallen, there were scarcely any churches existing worthy of the new state of things. Novel and great designs were formed: hitherto almost all the important churches of France belonged to the abbeys; now, under the royal patronage, cathedrals began to be built. The bishops, envious of the power of the monks, lent their powerful aid, and the whole of the laity, especially in the towns which were now emancipating themselves and forming independent communes, joined heartily in the work. With such a universal impulse, no wonder that architecture took a great stride and new forms were introduced. It is to this period and people that we owe the earliest development of the pointed Gothic style.

We have already seen at Vezelay how nearly the Burgundian monks had approached to Gothic. To complete the development it only required the side-walls and vaulting of the nave to be raised, so as to admit of windows over the roofs of the side-galleries; and the flying buttresses to be raised with them, so as to receive the thrust of the vault —the latter being constructed with pointed groin ribs, and the side and transverse arches carried to the height of the groins. The lay architects of the royal domain soon accomplished this step, and the new style sprung up and progressed with the most astonishing rapidity.

The earliest example we have of the fully developed Gothic style is the cathedral of St Denis, in which are deposited the remains of the kings of France. It was founded by the Abbé Suger in 1144. The cathedral of Notre Dame of Paris soon followed, and almost contemporary with it arose the magnificent cathedrals of Chartres, Rheims, Amiens, Beauvais, Bourges, and a host of others.

Another cause which tended much to hasten the progress of the style was the invention about the same time of painted glass (see GLASS, PAINTED). The Romanesque architects had been in the habit of decorating their churches with frescoes and other paintings; but this new mode of introducing the most brilliant colours into their designs was at once seized upon by the northern architects. The small round-arched windows, which were still in many instances retained long after the pointed arch had become usual in the vaulting, no longer sufficed when filled with stained glass to light the churches. They were therefore enlarged, two or even three were thrown into one, divided only by mullions; this compound window was again increased until the compartment of the clerestory became almost wholly absorbed. The architects were then forced to conform the arches of their windows to the pointed outline of the side-arches of the vaulting. This desire for more and more space for stained glass was the origin of the window-tracery which forms so beautiful a feature of the style. It is the last attenuated remains of the wall space of the clerestory, which was at last entirely absorbed.

Fig. 8, from Notre Dame, Paris, is a good illustration of the mode of progress of French Gothic. The left-hand portion of the elevation shows the kind of fenestration adopted. The clerestory windows are small; and, in order to admit more light, the windows and vault of the gallery are kept very high. This was the original design; but during the construction of the cathedral the importance of stained glass had become so great that the design was altered so as to give larger windows in the clerestory for its display, as shown on the right-hand portion of the elevation. The gallery is at the same time reduced to a mere triforium with very small windows, and the aisle windows are greatly enlarged. The upper or clerestory window also shows the simple early form of tracery; that in the aisle window being later and more advanced.

Fig. 8.

Fig. 9.

Fig. 9 shows two bays from Tournay Cathedral, and is a good specimen of the mode in which the whole space of the side-walls was made available for window-tracery and stained glass.

The further history of Gothic architecture in France is simply the enthusiastic following out, to their furthest limits, and in the most logical and artistic manner, of the principles above indicated, on which the early architects had unconsciously been working when they originated the style. So long as the Gothic architects worked on these principles they advanced and improved their architecture. When, however, the style had become fully developed and matured (about 1300 A.D.) the spirit of progress died. No new features were developed. The architects seemed to think that in its main elements their style was complete, and contented themselves with continuing the traditional style of their forerunners, and pushing to their extremest limits the principles handed down to them. They became proud of their scientific knowledge, and of the accuracy with which they could calculate and provide for the thrusts of the different arches, and the artistic element became subordinate to the engineering. The height of the cathedrals was extended till, at Beauvais, it exceeded the power of the architects to prop up the vaulting. The system of buttresses and pinnacles was developed with the utmost skill, till at last the original simplicity and repose of the designs were lost, and the exteriors presented a scientific but confused system of scaffolding and propping-up in stone (see BUTTRESS). The simple and beautiful forms of the early tracery became altered into all manner of flowing curves, graceful but unmeaning, in the Flamboyant period (q.v.); and, in short, the art became lost in mere cleverness of design and

dexterity of execution, and the architect's place was usurped by the freemason.

It is in the cathedrals of the 12th and 13th centuries, above referred to, that we find the noblest development of the Gothic style. Everything tended to this result. The nation was united in the effort—all the science, all the arts, all the learning of the times were centred in the church. In it, and that almost exclusively, the sculptor, the painter, the historian, the moralist, and the divine, all found scope for the expression of their ideas on the sculptured walls, porches, and niches, or the painted windows of the cathedrals—the churches of the people. The development of the decorative features progressed simultaneously with that of the constructional. The Roman acanthus and other enrichments were long followed, but gradually modified (as above mentioned) by Teutonic influence as shown in the hunting and fighting, as well as religious scenes represented in the 'historied' capitals and sculptures of their architecture wherever they penetrated. This style of carving became traditional, and was adhered to for centuries by the monastic orders. But at the revival of the 12th century these traditional forms were gradually departed from, and the architects sought inspiration for their sculpture directly from nature. At first the foliage was treated conventionally, but gradually came closer to nature, till in the completed style of the 14th century each leaf and flower exactly imitated the shape and embodied the spirit of the natural type. Mouldings, buttresses, pinnacles, and all the smaller features following the rule of nature were infinitely varied and beautiful. These will be treated of under their separate heads.

The progress of the Gothic style in other countries is no less remarkable than in France. At no time in the world's history did any style of architecture ever spread so wide, or give rise in such a short time to so many splendid buildings. No sooner had the style been invented in the central provinces of France, than it immediately spread over the west of Europe, superseding all other styles, and producing similar splendid buildings wherever it went.

We shall note shortly a few of the peculiarities of the style in England, Germany, and Italy. It spread also over the south of France and Spain; but in the latter countries it presents the character of an imported rather than that of a native or freely-adopted art.

English Gothic.—At the Conquest in 1066 the Normans introduced their round-arched style, some fine specimens of which still exist both in England and Scotland—St Cross, near Winchester; Durham Cathedral; Kelso and Jedburgh Abbeys, &c. But these buildings are not copies of those of Normandy. The English have always, in adopting styles, given them a national impress. As it was with the Norman, so it was to a still greater degree with the pointed Gothic, which was introduced into England about 1174 by William of Sens, who superintended the rebuilding of Canterbury Cathedral. The English architects soon began to follow out a pointed style of their own. They borrowed much from France, and worked it out in their own way, forming what is now called the *Early English* style. The differences between the early Gothic of France and England extend to almost every detail. The mouldings, bases, caps, pinnacles, buttresses, and foliage of the latter are all impressed with the early English feeling. In France the character of the early Gothic is one of unrest—a constant struggle forward. In England the effort after progress is not so distinct—that of carefulness and completeness prevails. In the *plans* of the cathedrals the differences are marked (see figs. 10, 11), as the accompanying plans of the cathedrals of Salisbury and Amiens show. The eastern termination of a French cathedral or church is invariably circular ended or apsidal—a form derived from the early Christian apse. The English cathedral, on the contrary, has almost always a square east end. The French transepts have almost no projection beyond

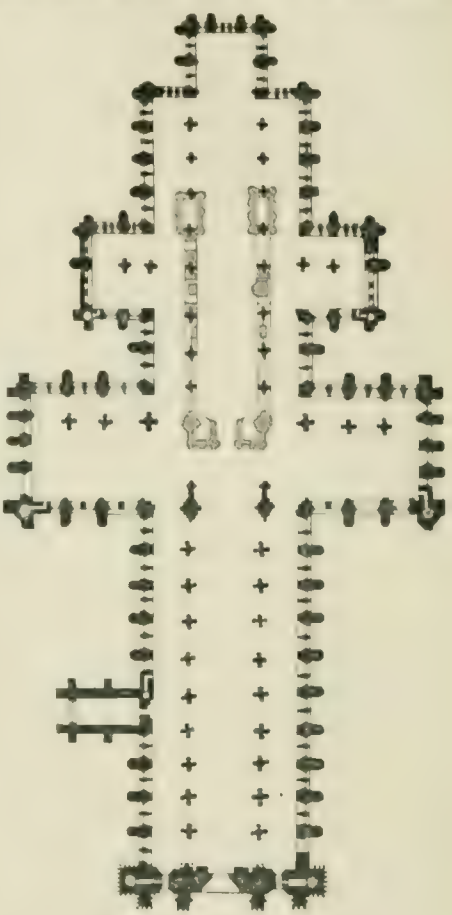

Fig. 10.—Salisbury Cathedral.

the line of the aisles; the English ones have great projections—Salisbury (q.v.) and Canterbury (q.v.) having *two* transepts. The French cathedrals are short and very lofty; the English, long and comparatively low. The French buildings are perhaps the grandest and most aspiring, the English the most finished and picturesque.

The construction of the exterior of the 'chevet' or apsidal east end was a difficulty with the French and Germans, and, as at Beauvais and Cologne (q.v.), resembles an intricate and confused mass of scaffolding. One of the churches in which this picturesque feature is most successfully carried out is St Ouen, Rouen. The great complication of pinnacles and flying buttresses which marks so many of the great French churches is here reduced to a minimum. This difficulty was avoided by the English square ends, which afforded scope for a large field of stained glass in a single great traceried window, as in most of the English examples.

The western portals of the French cathedrals, such as Rheims (see DOOR) and Amiens (q.v.), are among the boldest and most magnificent features of their architecture. In these the English were

occasionally not far behind, as the western portals of Peterborough and York show; but the English portals are generally smaller and less effective than the French ones.

The outlines of the English cathedrals are usually very picturesque and well balanced, the western

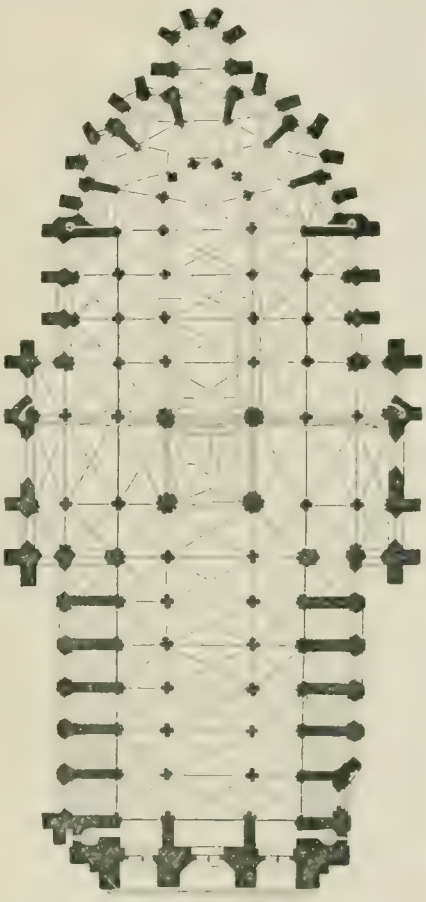

Fig. 11.—Amiens Cathedral.

towers grouping harmoniously with the central, and in this respect the English have the advantage.

The vaulting of the French churches is almost always quite simple in design, but in the application of vaulting the English carried out their own ideas. They were always fond of wooden roofs, and probably this may have led to the invention of the many beautiful kinds of vaults which form so fine a feature of English Gothic (see FAN-TRACERY). In England the style lasted longer than on the Continent, being retained till the time of Henry VIII. about the middle of the 16th century.

The Germans were nearly a century in adopting the pointed style after its invention in France; and when it was introduced it retained the appearance of a foreign importation. It never was so completely naturalised as in England. The so-called beauties of the German Gothic are, for the most part, to be regarded rather as excellent specimens of masonry than as artistic developments of the style. The open-work spires, for example, which are of frequent occurrence in England, are fine pieces of construction, and have a striking effect; but from the first there is a tendency to commit the work to masons, who rejoice in displaying their manual dexterity. The later Gothic in Germany is the most splendid development of the stone-cutter's art and the draughtsman's ingenuity; these run riot, while the artist is entirely wanting. The distortions of fig. 12 may serve as an example.

Fig. 12.

The Gothic style forced its way also into classic Italy, but there it was never understood nor practised in its true spirit. It was evidently an imitation from the beginning. The Italian architects tried to vie with those of the north in the size of their buildings, some of which, such as San Petronio at Bologna and Milan Cathedral, are enormous. The former illustrates the defects of Italian Gothic. The arches are very wide, and there are few piers. There is therefore a bare and naked effect, which is not compensated for by any richness of sculpture or colour. There is a want of *scale* about Italian Gothic buildings, as there is about those of Italian classic architecture, both ancient and modern. Size alone is depended on for producing grandeur of effect. No attempt is made to mark the size, and give a scale by which to judge of the dimensions of the buildings in those styles. A large classic temple is simply a small one magnified. In true Gothic architecture the case is different. Not only are the general dimensions magnified in a large edifice, but also the parts are multiplied. The columns and shafts remain of the same size, but their number is increased. The arches are enlarged in proportion to the general dimensions, but the caps, bases, and mouldings remain of the same size as in a smaller building, and thus indicate the greater size of the arch. A true Gothic building of large dimensions thus tells its own greatness, but in a classic or Italian Gothic edifice the size has to be found out. Stained glass was little used in Italy. It may have been intended to decorate the walls, which otherwise have such a bare and cold appearance, with frescoes—as indeed is the case in a few examples. The church of St Francis, at Assisi, is the most remarkable building of this kind, and is a very interesting example of fresco-decoration (see FRESCO). Italian Gothic, however, was most successful, especially in Venice and Verona, in domestic edifices, the palaces of those cities being amongst the finest structures of their kind in Europe. The medieval monuments of Italy, too, are especially beautiful and appropriate.

The towns of Italy, being early enfranchised, have also many municipal buildings in the Gothic style; and to these, as well as to those of Belgium, allusion is made in the articles on the several towns and in MUNICIPAL ARCHITECTURE.

We might, in the same manner, trace the Gothic style in all the other countries of western Europe; but its history is similar in all. It is in England and France that the true spirit of the style was most felt and the finest examples remain. Our space has not permitted us to enter minutely into the various styles of Gothic in each country. The

more important of these will be treated separately (see EARLY ENGLISH, DECORATED, PERPENDICULAR, FLAMBOYANT).

We may, however, state generally that both in France and England the style had a complete existence—it was born, arrived at maturity, and died. When the spirit of the early architects had pushed the design to its utmost limits they rested from their labours, well satisfied with their splendid achievements. Their successors occupied themselves with forms and details, and with the perfecting of every minute part. The art finally passed away, and left architecture in the hands of trade corporations—masons, carpenters, plumbers, &c.—who monopolised the whole work, and acted independently, to the exclusion of one directing mind. The result was as we have seen: architecture became masonic skill, and Gothic was finally superseded by the revival of classic architecture in the 16th century. The Renaissance of the arts of Greece and Rome during the last two or three centuries has in the 19th century been followed by a revival of Gothic architecture. Even during the 17th and 18th centuries a few attempts were made to resuscitate the old style in churches, and in the 18th century a bold effort in the direction of introducing it into domestic architecture was undertaken by Horace Walpole, Batty Langley, and others. But the present revival may be said to have fairly commenced in 1819, when Rickman published his *Attempt to discriminate the Styles of English Architecture*, a very careful and complete work, the conclusions of which have been generally adopted and adhered to. Other works by Pugin, Cotman, Britton, and others soon followed, illustrative of Gothic architecture both at home and abroad. One of the most prominent supporters of the revival was Augustus W. Pugin (1812–52), who both by his writings and in his practice brought the Gothic style practically before the public in the first half of the 19th century. Since that time it has been greatly used, almost all our modern churches and many other public buildings being designed in the Gothic style. The names of Edward Barry, George Gilbert Scott, E. Street, and Burgess are well known in connection with the Houses of Parliament, the Law Courts in London, and numerous churches and cathedrals both in England and abroad. A reaction has within recent years taken place, especially in secular structures, but Gothic is still regarded as the most suitable style for ecclesiastical edifices.

In the United States classical models were generally followed, even in ecclesiastical architecture, till the building of Trinity Church, New York, in 1840, by Richard Upjohn—the first instance in which the Gothic style (English Gothic) was used with skill. Since then Gothic has been the prevalent style for churches; and a modified Gothic, mainly North Italian, has also been much used for civil buildings in the United States.

In France, the land of its birth, Gothic architecture has been very thoroughly studied, and its principles and beauties have been admirably analysed and illustrated, notably in the splendid work by the late Viollet-le-Duc, *Le Dictionnaire raisonné de l'Architecture française*.

The beauties of Italian Gothic have also had their admirers, and have been charmingly described and illustrated by Ruskin. But this style has not been much adopted in northern countries.

In the changes of fashion with regard to architecture Gothic may at present appear to be receding, but the study and elucidation of its principles have done much to modify men's views with regard to the elements of the art, and will doubtless continue to influence the principles and practice of the architecture of the future.

See Bloxam's *Principles of Gothic Architecture* (1829; 11th ed. 3 vols. 1882), Rickman's *Gothic Architecture*, by Parker (1848); Britton's *Antiquities of Great Britain* (1805–); Pugin's works, such as the *Examples of Gothic Architecture* (1835) and the *Specimens*, &c. (1823); E. Sharpe's *Architectural Parallels* (1848); Viollet-le-Duc, *Dictionnaire* (1854–69); Street's *Brick and Marble of Middle Ages* (1874) and *Gothic Architecture in Spain* (1869); Ruskin's *Stones of Venice* (1851–53); Fergusson's *History of Architecture* (1865–76).

Gothland (Swed. *Gotaland* and *Götarike*), the southernmost of the three old provinces of Sweden, with an area of 35,800 sq. m. and a population of over two and a half millions. — (2) A Swedish island (Swed. *Gottland*) in the Baltic, 44 miles E. from the mainland, constitutes with Farö, Gotska, Sandö, and other smaller islands the province of Gottland or Wisby. Area, 1217 sq. m. The island consists mainly of terrace-like slopes of limestone, which are encircled by cliffs broken by numerous deep fiords, more especially on the west coast; the eastern parts are flat. The climate is mild. Next to agriculture, the chief occupations of the inhabitants, (a little over 50,000) are shipping, fishing, sealfishing, fowling, and lime-burning. In the middle ages the island belonged to the German Hanseatic League, but was restored to Sweden in 1645. The capital is Wisby (q.v.).

Goths. The native name of the Teutonic people known as Goths (in Lat. *Gothi*, *Gotthi*) had the two forms *Gutans* (sing. *Guta*) and *Gutos* (sing. *Guts*); from the latter was formed the compound *Gut-thiuda*, 'people of the Goths.' Their earliest known abode was on the southern coasts and the islands of the Baltic. The island Gothland derives its name from them. The Scandinavian traditions, reduced to writing in the 12th century, speak of a country on the Baltic called *Hreidhgotaland*, which must have owed its name to the branch of the Goths called in Anglo-Saxon poetry Hræde, and (perhaps with etymologising corruption) Hréthgotan and Hréthas. The Hrædе are stated in an Anglo-Saxon poem (*Widsith*) to have had their home on the Vistula. Whether Goths ever inhabited the Scandinavian peninsula is doubtful; the 'Gothland' of Sweden is etymologically not 'the land of the Goths,' but 'the land of the Gauts' (in A.S. *Géatas*), a distinct, though doubtless a kindred people.

The native tradition of the Goths, according to their historian Jordanis (6th century), represented them as having originated from Scandinavia. This tradition, however, is probably a mere development of the common Teutonic myth which placed the creation of mankind in an unknown region beyond the northern sea, and has therefore no historical value.

The elder Pliny (died 79 A.D.) mentions the Goths (*Guttones*) in two passages of his *Natural History*, once in a mere enumeration of the Germanic peoples, and once in what purports to be a quotation from the Greek traveller Pytheas (4th century B.C.). If Pliny's citation be accurate, Pytheas referred to the Guttones as dwelling on the shores of an estuary called Mentonomon, and as trading in amber, gathered by the inhabitants of an island distant from them a day's sail. It has, however, been suggested that the people mentioned by Pytheas were the Teutones living near the mouth of the Elbe. In a Greek MS. it would be easy to misread *Teutones* as *Guttones*, and the former name actually occurs in the context. But even if this be so, we may perhaps infer that in Pliny's time the 'Guttones' were a maritime people, as he quotes the supposed statements of Pytheas without any remark. A generation later the Goths (*Gotones*, *Gothones*) are spoken of by Tacitus, who says that among them the kingly power was greater than

among the other Germanic peoples, though they still retained their freedom. He relates that in the reign of Tiberius a Marcomannic exile named Catualda, who was resident among the Gotones, collected an army and made himself king of the Marcomanni. The indications given by Tacitus seem to imply that he regarded the Goths as the easternmost people of Germany (the boundary of which was the Vistula), and that their territory reached to the Baltic. Their southward emigrations must have commenced soon afterwards, for the geographer Ptolemy (2d century) assigns to the 'Gythones' a position in Sarmatia (on the *right* bank of the Vistula), divided from the sea by the Slavonic Wends. The history of their southward wandering is unknown, the story told by Jordanis being obviously mythical. What seems certain is that early in the 3d century the Goths, vastly increased in numbers by the accession of many conquered peoples, were occupying a territory north of the Black Sea and the Danube mouths. The eastern portion of them received the distinctive names Ostrogoths ('East Goths') and Greuthungs ('dwellers on the sand'), while the western portion were called Visigoths ('West Goths') and Thervings (probably 'dwellers among the trees'). Mingled with the Goths proper, or adjoining them, were a number of other East Germanic peoples who, like them, had emigrated from the Baltic coasts. Chief among these were the Vandals and the Gepidæ, the neighbours of the Goths on the west and on the north respectively. The geographical position of the Heruli, Burgunds, Scirians, Rugians, and Turcilings at this time cannot be determined. All these nations were often classed together under the general name of Goths.

In the reign of the Emperor Philip the Arab (248-49) the Goths are said to have been ruled by a king named Ostrogotha. (There is no strong reason for regarding this name as an etymological figment: it does not mean 'Ostrogoth,' but is to be compared with such Teutonic names as Austrowald, Easterwine, Earcongota.) In his reign a war broke out between the Goths and the Roman empire; at the battle of Abritta the Romans were totally defeated, and the Emperor Decius and his son were killed. For eighteen years the eastern provinces of the empire suffered terrible ravages from the Goths, but these calamities were avenged by the victories of the Emperor Claudius (thence surnamed Gothicus). After the death of Claudius in 270, his successor Aurelian conceded to the Goths the province of Dacia, on condition of furnishing a body of 2000 men to the imperial army. Such of the native inhabitants as did not choose to remain as subjects of the Goths were provided with new settlements south of the Danube. With some interruptions, the peaceful relations between the Goths and the Romans continued for more than a hundred years. During this period the old names Visigoth and Ostrogoth received a new sense as expressive of a national distinction. The Visigoths or Thervings of later history are the descendants of the people established by Aurelian in Dacia; the Ostrogoths or Greuthungs are the descendants of the Goths who remained in southern Russia.

In the 4th and succeeding centuries writers who affected classicality of diction frequently applied to the Goths the obsolete names of Getæ and Scythians, which in antiquity belonged to the inhabitants of the regions in which the Goths were now settled. Usually the Goths were regarded as the actual descendants of these historic peoples, and the name *Gothi* seems to have been imagined to be a corruption of *Getæ*. In the 6th century Cassiodorus, followed by the Goth Jordanis, endeavoured to blend into one story the facts of Getic history, taken from Herodotus and other classical writers, and the Gothic traditions of a migration from the extreme north. In modern times the hypothesis of the identity of Goths and Getæ has been advocated by so distinguished a scholar as Jacob Grimm, but is now generally rejected.

In the middle of the 4th century the Ostrogothic king Ermanaric established by conquest a powerful empire, extending from the Black Sea to the Gulf of Bothnia. About the year 375 this empire was subjugated by the Huns. The Visigoths, with a small portion of the Ostrogoths, escaped a similar fate by crossing the Danube, and placing themselves under the protection of the Roman empire. The oppression of the provincial governors soon provoked a revolt. The eastern emperor, Valens, collected a great army and marched into Thrace for the purpose of subduing the barbarians; but at the battle of Adrianople (August 9, 378) the Romans suffered a ruinous defeat, and Valens himself was killed. The Goths, however, were too ill organised to make effective use of their victory, and Theodosius, the successor of Valens in the empire of the East, and afterwards sole sovereign of the Roman empire, found it possible in a few years to bring back to their allegiance the whole Gothic people, excepting those who were under the yoke of the Huns. This result was not attained without great and dangerous concessions. The Visigoths received large grants of land in Thrace, and the Ostrogoths in Phrygia. They were permitted to govern themselves by their own laws, and 40,000 of their warriors were embodied into a separate army (called *fœderati*), receiving a high rate of pay. Many of their nobles also were promoted to high positions in the imperial service. So long as Theodosius lived these measures were successful in securing the loyalty of the Goths; but the excessive favour shown to barbarians who had so lately been enemies provoked serious discontent.

The Goths thus incorporated into the Roman empire had for the most part been converted to Christianity; principally, it is believed, owing to the labours of the Arian bishop Wulfila or Ulphilas (q.v.), a Goth who had received a learned education at Constantinople, and who lived as a missionary among the Visigoths from 340 to 381. The new faith was with extraordinary rapidity accepted, not only by the two great branches of the Gothic people, but by all the smaller nations of kindred race. For two hundred years the Goths remained faithful to the Arian creed taught by Wulfila and his disciples. Unlike the Vandals, who were adherents of the same sect, the Arian Goths were honourably distinguished by their freedom from bigotry. Although themselves the object of the most virulent religious hatred, they were, even at the height of their power, very seldom guilty of persecution.

On the death of Theodosius in 395 the sovereignty of the Roman world was divided between his two sons, Arcadius becoming emperor of the East, and Honorius emperor of the West. One of the first acts of the ministers of Arcadius was to lower the pay of the Gothic soldiery. The Visigoths at once rose in rebellion, and, electing as their king a young officer of distinction named Alaric (q.v.), proceeded to overrun Greece. The emperor was compelled to make terms: Alaric was made military governor of Eastern Illyricum, and remained quiet for three years, preparing for an irruption into Italy. In the year 400 he entered the peninsula, but apparently met with no great success. After being defeated by Stilicho at Pollentia (Easter Sunday, 402), he retired to Illyria, receiving, however, a large sum of money from the Romans as the price of peace. A second invasion in 408, provoked by the

disregard of treaty obligations on the part of the Romans, had very different results. Stilicho was dead, and the barbarian soldiers of Italy, exasperated by official tyranny, deserted to the standard of Alaric in great numbers. Rome was thrice besieged; twice the city was saved by the submission of the senate, but on the third occasion it was taken by storm and delivered up to plunder. Although terrible excesses were committed by the Goths, the Roman writers speak with great admiration of the humanity and moderation displayed by Alaric himself. Honorius, secure in the impregnable fortress of Ravenna, and encouraged by hopes of support from Constantinople, refused to come to terms, and Alaric was preparing to effect the entire subjugation of Italy, when his career was cut short by death in 410.

Alaric's successor, Atawulf, abandoned the design of conquering Italy, and led his people into southern Gaul. At Narbonne he married the daughter of Theodosius, the princess Galla Placidia, who had been taken captive by Alaric in Rome. On the approach of a Roman army under Constantius the Visigoths crossed the Pyrenees into Spain, where Atawulf was murdered in 415.

The next king, Wallia, submitted to the Romans, and in the name of the empire conquered nearly the whole of Spain. As the reward of his services, he received permission to settle with his people in the south of Gaul.

The 'kingdom of Toulouse,' founded by Wallia in 418, was increased by the conquests of his successors, until under Euric (who died in 485) it included the whole of Gaul south of the Loire and west of the Rhone, as well as Provence and the greater part of Spain. The most noteworthy event in the history of this kingdom was the great battle fought in 451 on the Mauriac plains near Troyes (commonly miscalled the battle of Chalons), in which the Visigoths under their king Theoderic (or Theoderid) I., united with the Romans and the Franks, inflicted a crushing defeat on the vast army of the Huns under Attila (q.v.). Theoderic was killed, but the result of the battle was the dissolution of the Hunnish empire, and the salvation of European civilisation from the deluge of barbarism which had threatened to overwhelm it.

In the reign of Alaric II., the successor of Euric, the kingdom of Toulouse came to an end. The Frankish king Clovis (Chlodovech, Hlôdawîh), whose recent conversion to Catholic Christianity enabled him to give to a war of unprovoked aggression the specious aspect of a crusade against the heretics, invaded the Visigoth territories in 507. The battle fought on the 'field of Voclad,' near Poitiers, decided the sovereignty of Gaul. Alaric was killed, and the Visigoths abandoned to the conqueror all their territories north of the Pyrenees, retaining of their Gaulish possessions only a small strip of country bordering on the Gulf of Lyons. The subsequent history of the Visigoths must be reserved until we have related the history of their Ostrogothic kinsmen.

After their subjugation by the Huns in the later part of the 4th century, the Ostrogoths, Gepidæ, and the smaller 'Gothic' peoples appear to have adopted the nomad life of their conquerors, and they formed part of the vast horde which followed Attila into Gaul. On the collapse of the Hunnish dominion these nations regained their independence. The Ostrogoths settled first in the neighbourhood of Vienna, under their king Walamer, a member of the Amaling family, who traced their descent through Ermanaric and Ostrogotha to a legendary hero named Amala. Immediately after their emancipation the Ostrogoths are found occupying the position of mercenaries of the Eastern Empire. In 462 the friendly relations between Walamer and the emperor, which had been for a time relinquished, were renewed, and Walamer's nephew, Theoderic, the son of Theodemer, a boy eight years old, was sent as a hostage to Constantinople, where he remained ten years, receiving the education of a Roman noble. Shortly after his return the Ostrogoths, pressed by famine, abandoned their homes, and migrated in a body towards the south-east. Their inroads in Mœsia and Thrace caused great alarm at Constantinople, and the emperor was constrained to purchase peace by granting them permission to settle in Macedonia, and by bestowing on them large gifts of land and money.

In 474 the young Theoderic became king of the Ostrogoths. After fourteen years spent in petty warfare, sometimes as the ally and sometimes as the enemy of the Romans, he obtained from the Emperor Zeno permission to wrest the dominion of Italy from the usurper Odovacar (Odoacer, q.v.). Like most of the military expeditions of the Goths, the invasion of Italy was the emigration of an entire people; and the number of persons who accompanied the march of Theoderic was probably not less than a quarter of a million. After a war of five years the work of conquest was completed by the capture of Ravenna and the submission of Odovacar, who, it is said, was soon afterwards brutally and treacherously murdered by Theoderic's own hand.

Notwithstanding this evil beginning, the thirty-three years' reign of Theoderic in Italy was one of singular humanity and wisdom, and secured for the country a degree of tranquillity and prosperity such as it had not enjoyed for centuries. The historian Procopius, though a Byzantine courtier, pronounces him not inferior to the best and wisest of Roman emperors. The partisans of Odovacar received a general amnesty; the necessary provision of lands for the Goths was carefully carried out so as to press as lightly as possible on the native population; the fiscal and judicial systems were reorganised, and all acts of extortion or injustice on the part of officials were sternly repressed. The Goths and the Romans continued to be distinct nations, each judged by its own tribunals and by its own laws, limited and supplemented by a new code containing a few provisions which were made binding on all the subjects of the kingdom. The Catholics were granted entire equality with the adherents of the king's own faith; the Jews, in all other Christian lands the victims of oppression, enjoyed under Theoderic full liberty of worship, and protection from all encroachment on their civil rights. It is impossible to read the official letters written in Theoderic's name by his Roman secretary, Cassiodorus, without the deepest admiration for the king's unwearied energy and enlightened zeal for the welfare of his subjects. It is true that in the last three years of his life, when he was worn by age and harassed by suspicions of widespread treason, his fame was tarnished by the judicial murders of Boethius and Symmachus, and by acts of oppression directed against the Catholic Church. But there have been few possessors of absolute power who, on the whole, have used it so nobly.

Theoderic died in 526, and his daughter Amalaswintha was appointed regent on behalf of her son Athalaric, then ten years old. When Athalaric died at the age of sixteen, Amalaswintha associated with herself in the kingdom her father's nephew, the base and cowardly Theodahad, by whose orders she was soon afterwards murdered. Theoderic had not long been dead before the disordered state of the kingdom testified to the incapacity of his successors; and the Ostrogothic power was threatened by a new danger in the ambition of the Emperor Justinian, who, not content

with the formal acknowledgement of supremacy which had satisfied his predecessors, was resolved to make Italy an integral part of his own dominions. In 536 the great general Belisarius was sent for the purpose of conquering the country. The Goths deposed Theodahad, and elected to the throne a distinguished soldier named Witigis, who, on his elevation, married Amalaswintha's daughter Mataswintha. After four years Belisarius, though enormously overmatched in numbers, had subdued all but the extreme north of Italy, and held Witigis and his queen prisoners, when he was recalled by Justinian's jealousy to Constantinople.

Soon after his return the oppression of the imperial representatives in Italy not only provoked into revolt the Goths who had submitted to Roman rule, but excited mutiny among the Roman soldiers, who deserted to the enemy in great numbers. In a few months the new king of the Goths, Hildibad, who had previously maintained a precarious footing in the north, found himself at the head of a powerful army. His career, however, was cut short by assassination; and after a short interregnum the Goths conferred the crown on his nephew Totila, otherwise named Badwila. After a struggle of a few years, in which Totila displayed not only brilliant military talent, but a chivalrous generosity and humanity which extorted the admiration of his enemies, the imperial cause in Italy was felt to be desperate, and in 544 Belisarius was again sent to take the command of the army. But owing to the insubordination of his officers, and to other causes, he had little success, and after five years was recalled at his own request. The enterprise in which Belisarius had failed was accomplished by the aged eunuch Narses, who, in 552, landed in Italy at the head of a colossal army. The Ostrogoths suffered a crushing defeat at Taginæ (Tadino), where Totila was killed. His successor, Teia, fell a few months later in the battle of Mons Lactarius, near Vesuvius. The remnant of the defeated army was suffered by Narses to march unmolested out of Italy; their subsequent fate is unknown. In the course of the next two years the few outstanding Gothic garrisons surrendered, and Italy became a portion of the Byzantine empire. The nation of the Ostrogoths had ceased to exist.

We now return to the history of the Visigoths. The conquering progress of Clovis, after the battle of Voclad in 507, was checked by the armed intervention of Theoderic the Ostrogoth, who compelled the Franks to leave the Visigoths in possession not only of their Spanish dominions, but also of a small tract of country in Gaul, including the cities of Carcassonne, Narbonne, and Nimes. The former Visigothic territories in Provence Theoderic annexed to his own kingdom, and he assumed the guardianship of his infant grandson Amalaric, the son of Alaric II. During Theoderic's life the Visigothic kingdom was administered by him in the name of Amalaric; in Spain, however, his general Theudis practically reigned as a tributary king. After Theoderic's death Amalaric was acknowledged as sovereign of the Visigoths, but his direct rule was confined to the Gaulish dominions, Theudis still retaining the real authority in Spain. A defeat by the Franks having caused Amalaric to cross the Pyrenees, he was murdered in 531 by order of Theudis, who then assumed the crown, and reigned till he died by an assassin's hand in 548. The Visigothic state now became what it had been prior to 419, a purely elective monarchy, and the choice of the kings was frequently attended by civil war. Athanagild, who was placed on the throne by a rebellion in which he was aided by an army from Justinian, reigned prosperously for fourteen years (554–567); but his Byzantine allies (the 'Greeks,' as they were called) seized several of the Spanish cities, and were not completely dislodged until about 625.

The brilliant reign of Leovigild, who made Toledo the capital of the kingdom, was marked by the subjugation of the Suevic kingdom in northwestern Spain and Portugal. In 572 Leovigild associated with himself in the kingdom his two sons, Ermenegild and Reccared. The former, a convert to Catholicism, rebelled against his father, but after two years was conquered, and afterwards put to death. It is said that he was offered his life and restoration to his royal dignity if he would return to the Arian faith. By the Catholic Church he was reverenced as a martyr, and was formally canonised by Pope Sixtus V.

On the death of Leovigild his son Reccared, already a crowned king, succeeded without the formality of election. One of his first acts was to announce his determination to adopt and to establish the Catholic religion. The Goths, who were evidently weary of their position of ecclesiastical isolation, and had lost interest in their hereditary creed, accepted the change with surprising readiness. Revolts took place in Gaul and in the former Suevic kingdom, but these were soon suppressed; and the Arian clergy and laity were in overwhelming numbers admitted into the Catholic Church.

The conversion of the Visigoths was a political necessity. The secure establishment of their dominion was impossible so long as they were divided from the subject people by religious differences, and had against them the powerful organisation of the Spanish Church. This formidable adversary was now converted into an ally; but unhappily the weakness of the monarchy enabled the church to exact ruinously great concessions as the price of its support. In the course of the 7th century the Visigothic state became gradually more and more subservient to the church. The kings were elected by an assembly of bishops and court officials, the former often being in a large majority. The three sovereigns who succeeded for a time in vindicating their independence—Swinthila (620–631), Kindaswinth (641–649), and Wamba (672–680)—were eventually either deposed or induced to abdicate; and in the next reign the ground lost by the church was always more than regained. It is hardly too much to say that under the more ecclesiastically-minded kings the country was governed mainly in the interests of the clerical order; and on the whole the influence of the priesthood was so exercised as to foster, instead of to check, the many causes of decay and disorganisation which brought about the ruin of the kingdom. The efforts of Witica (701–710) to carry out extensive reforms in church and state were indeed seconded by the Archbishop of Toledo, but were virulently opposed by the great body of the clergy. Of his successor, Roderic, 'the last of the Goths,' legend has a great deal to say, but history knows only that his defeat on the banks of the Guadalete (August 711) placed the dominion of Spain in the hands of the Moorish invaders. Under the pressure of the Moslem yoke the Christians of the Peninsula became united into one nation, and the Goths ceased to exist as a separate people; but the Spanish nobility have always laid claim to Gothic descent.

The last portion of the Gothic race to disappear as a distinct community was that branch of the Ostrogoths (known in the 6th century as *Tetraxitæ*) who inhabited the Crimea from the time of Ermanaric. In the reign of Justinian these Goths received a Catholic bishop from Constantinople, and in the official language of the Eastern Church 'Gothia' continued to be the name of the Crimea

down to the 18th century. In 1562 the famous traveller Busbecq met at Constantinople with two Crimean envoys, and wrote down a long list of words of their language, which he recognised as having an affinity with his native Flemish. The words are for the most part unquestionably Gothic. It is possible that in the Crimea the Gothic speech may have survived to a much later time; in 1750 the Jesuit Mondorf learned from a native of that region, whom he had ransomed from the Turkish galleys, that his countrymen spoke a language having some resemblance to German.

The Gothic language is now classed by philologists as belonging, together with the Scandinavian dialect, to the 'East Germanic' group, so called in contradistinction to the 'West Germanic,' which includes Old English and Low and High German. In some of its features the East Germanic form of Teutonic speech is more primitive than the other branch—e.g. in the preservation of the inflexional final *-z* (becoming in Gothic *s* and in Old Norse *r*), which in West Germanic is lost. On the other hand, there are certain features (such as the substitution of *-aggw-*, *-iggw-*, for the original *-anw-*, *-inw-*) in which the eastern branch shows a later stage of development. As the Bible translated by Wulfila is several centuries older than the earliest written remains of any other Teutonic language, the value of Gothic in the study of Teutonic philology is very great, although the mistaken notion that it represents substantially the ancestral form of the Teutonic languages as a whole led the scholars of an earlier generation into many errors which are still often repeated in popular handbooks. The Gothic written character, believed to be the invention of Wulfila, is substantially an adoption of the ordinary Greek alphabet of the 4th century, some letters, however, being taken from the Latin, and others from the Runic alphabet used by the Goths before their conversion. The most scientific grammar of the language is that of W. Braune (Eng. trans. 1883); Douse's *Introduction to the Gothic of Ulphilas* (1886) is also valuable. The most complete dictionary is still that of Schulze (Magdeburg, 1848), which gives full references to the passages in which the words occur, and also the Greek words which they render in Wulfila's translation. It should, however, be checked by comparison with later works—e.g. with Schulze's abridgment of 1867, or the concise dictionaries of Heyne and Bernhardt. A useful vocabulary, with an outline of the grammar, has been published by Professor Skeat (1868).

The scanty written remains of the Gothic language are scarcely entitled to the name of literature. Wulfila's translation of the Bible, however, is a work of extraordinary ability, and from its early date and its extreme faithfulness is of some value for the textual criticism of the New Testament. The extant portions comprise the greater part of the four gospels, parts of St Paul's epistles, and some verses of Ezra and Nehemiah. The remaining Gothic writings are a portion of a commentary on the gospel of St John, two title-deeds referring to property at Ravenna and at Arezzo, and a fragment of a Gothic calendar. All the existing Gothic MSS. seem to have been written in Italy in the first half of the 6th century. The most important of these, the beautiful *Codex Argenteus* of the gospels, was discovered in the 16th century in the monastery of Werden in Westphalia, and is now at Upsala. Of Gothic inscriptions in the Runic character only three are known, all probably belonging to the 4th century; two of them are merely men's names (Tilarids, Ranya) scratched on spear-heads, and the third consists of the words *Gutani ƕi* (or *ƕkwi*) *hailag*, 'the holy . . . of the Goths,' on a gold necklet found in 1838 at Petrossa in Wallachia. See Henry Bradley, *The Goths, to the end of the Dominion in Spain* ('Story of the Nations' series, 1888).

Götterdämmerung. See RAGNAROK.

Gottfried von Strasburg, a famous mediæval German poet, who flourished about the close of the 12th and the beginning of the 13th century, contemporary with Hartmann von Aue, whom he celebrates as the first of German narrators, Wolfram von Eschenbach, to the prologue of whose *Parzival* he alludes, and Walter von der Vogelweide. Gottfried's poem, *Tristan und Isolde*, extends to 19,552 short rhymed lines, but was left unfinished, and ends abruptly. It was completed about 1210, and he himself died between that year and 1220. The story itself is of course of Celtic origin; and there is hardly another theme that has laid such a potent spell upon the imagination of poets in every age. Gottfried's immediate source was a poem of the French trouvère Thomas, of which only fragments now exist; but in his hands the theme has been treated with a new poetic vigour and mastery at once of pathos and of passion. Gottfried's works, with later continuations of *Tristan* by Ulrich von Turheim and Heinrich von Freiberg, were published by Fr. Heinrich von der Hagen (1823). The best edition is that of Bechstein (2d ed. 1873). Modern German translations have been given by Kurtz (1844), Simrock (1885), and Wilh. Hertz (1877). Wagner has made use of *Tristan* for his opera *Tristan und Isolde*. See works by Franck (1865) and Golther (1887).

Gotthelf. See BITZIUS.

Göttingen (10th century *Gutingi*), a town in the former kingdom of Hanover, lies 538 feet above sea-level in the Leine's wide valley, encircled by gentle hills—the highest, the Hainberg (1246 feet). By rail it is 67 miles S. of Hanover, and 36 NE. of Cassel. The ramparts, long since outgrown, and now planted with lindens, form a charming promenade; but architecturally Göttingen has nothing much to boast of—a quaint *rathhaus*, a statue of William IV., and a few antique buildings, one of which, the Jacobikirche, has a steeple 320 feet high. The celebrated university (*Georgia Augusta*) was founded 1734–37 by Baron Münchhausen, under the auspices of George II., Elector of Hanover and king of England, and now has 120 professors of various grades, and more than 1000 students of philosophy, theology, medicine, and jurisprudence. Connected with it are the library of 500,000 volumes and 5000 MSS., the art museum, the splendid botanic garden (laid out by Haller), the observatory, the laboratory, the lying-in hospital, &c., as also the Royal Society (1750) which publishes the well-known Transactions and the *Gottinger Gelehrte Anzeigen*. Longfellow, Motley, Ticknor, Bancroft, and several other illustrious Americans studied at Göttingen, whose native *alumni* include many of Germany's most famous sons. The 'Göttinger Dichterbund' was a small poet band (Voss, the two Stolbergs, Klopstock, Bürger, &c.) who, in the 'Storm and Stress' days of 1770–78 did much for the revival of national feeling; by the 'Göttinger Sieben' are meant the seven professors (Albrecht, Dahlmann, Ewald, Gervinus, the two Grimms, and Weber) who for their liberal tendencies were in 1837 expelled by King Ernest Augustus. The book-trade is of more importance than the manufactures—woollens, sugar, chemicals, &c. Pop. (1875) 17,057; (1885) 21,598, of whom 1714 were Catholics, and 536 Jews. Raised to a town in 1210, and a considerable member of the Hanse in the 14th century, Göttingen suffered much during the Thirty Years' War, when it was taken by Tilly in 1626, and recaptured by the

Swedes in 1632. See works by Frensdorff (1878) and Hasselblatt (1881).

Gottschalk, a monk of Fulda, studied Augustine's works in the monastery at Orbais in the diocese of Soissons, and adopted such strong views on Predestination (q.v.) that Rabanus (q.v.), Archbishop of Mainz, had him condemned as a heretic in 848. His own archbishop, Hincmar (q.v.) of Rheims, deposed and imprisoned him; and though Gottschalk recanted under the lash, he died in prison 868.

Gottschall, Rudolf von, poet and novelist, born at Breslau 30th September 1823, made his début with poems in 1842. Successful plays were *Pitt und Fox* and *Lambertine von Mericourt*. *Die Göttin* (1853) and *Carlo Zeno* (1854) were epic poems. *Die Deutsche Nationalliteratur des 19ten Jahrhunderts* (4 vols. 1855–92) and *Poetik* (6th ed. 1893), are his most important books on the history of literature. His dramatic works (including *Catharine Howard*, *Amy Robsart*, and *Arabella Stuart*) fill 12 volumes; his novels (including *Withered Leaves*, translated 1879) are numerous, as also essays published in *Unsere Zeit* and other magazines edited by him; and he published several records of travel (Italy, Paris, &c.). He was ennobled in 1877.

Gottsched, Johann Christoph, an important figure in the history of German literature, was born at Judithenkirch, near Königsberg, in Prussia, February 2, 1700. At the university of Königsberg he studied philosophy, belles-lettres, and languages. In 1724 he removed to Leipzig, where in 1730 he became professor of Philosophy and Poetry, and in 1734 professor of Logic and Metaphysics. He died 12th December 1766. Between 1729 and 1740 Gottsched exercised a sort of Johnsonian dictatorship in the world of polite literature in Germany. At first he laid down, in various periodicals which he edited, rules and theories for the composition of poetry, and sharply criticised the bombastic absurdities of the Silesian school of poets. At the same time he laboured, to the best of his abilities, to improve his mother-tongue as a literary vehicle, by aiming at greater polish, formal completeness, and elegance. But his chief endeavours were directed to the reformation of the German drama, a work in which, in co-operation with the Neubers, he did indeed effect a very meritorious alteration, in that he raised the moral tone, the literary workmanship, and the taste of the acting plays, banished the coarse buffooneries of Hanswurst ('Jack Pudding') from the boards, and recommended as models the best class of French theatrical pieces. But his reforming zeal carried him too far, and brought him on to the dangerous ground of excess. He became pedantic and vain; his critical faculty became distorted; he manifested a petty jealousy of all literary authority save his own, opposing himself to the Swiss writers Bodmer and Breitinger, and refusing to see any merit in Klopstock and Lessing. His own model drama, *The Dying Cato* (1732), notwithstanding its immense success, is sadly barren of poetry and dramatic action. He did, however, leave one useful work, *Nothiger Vorrath zur Geschichte der Deutschen dramatischen Dichtkunst* (1757–65), an unfinished catalogue of plays from 1450 to 1760. See Danzel, *Gottsched und seine Zeit* (1848); and Bernays, *Goethe und Gottsched, zwei Biographien* (1880).

Götz von Berlichingen, 'of the Iron Hand,' a German knight of the 16th century, was born at Jaxthausen, in Würtemberg, in 1480. (Götz is an abbreviation of Gottfried.) His education was conducted by his uncle Conrad, with whom he attended the diet of Worms in 1495. From 1497 onwards to 1525 his restless spirit, and the general turbulence of the time, involved him in continual feuds, in which he displayed a mixture of lawless daring and chivalrous magnanimity. At the siege of Landshut (1505) he lost his right hand, which was replaced by an artificial one of steel, cunningly invented by himself; it is still shown at Jagstfeld. Twice he was declared under the ban of the empire for acts which were little better than acts of brigandage or highway robbery—in 1512 for plundering a band of Nuremberg merchants, and in 1516 for carrying off Count Philip of Waldeck and extorting a large ransom for his liberation. Having joined Duke Ulrich of Würtemberg when this prince was attacked (1519) by the Swabian league, Götz, after making an heroic defence of Möckmühl, was, contrary to the articles of his capitulation, taken prisoner, and only released at the intercession of his friends, George von Frundsberg and Franz von Sickingen, on payment of 2000 florins ransom. In the Peasants' War of 1525 he took part with the insurgents and was chosen leader of a part of their forces. This step he ascribes to compulsion; more likely it was the result of his own restless and turbulent spirit, and of a desire for revenge on his old enemies of the Swabian league. Although acquitted of blame for his participation in this affair by the supreme court of the empire, he was nevertheless captured by his enemies of the Swabian league, kept a prisoner at Augsburg for a couple of years, and at last sentenced to perpetual imprisonment in his own castle, and, in case of his breaking this condition, to a fine of 20,000 florins. He was only freed from this irksome bondage on the dissolution of the league in 1540. Two years later he was again in action, fighting with the emperor in Hungary against the Turks, and two years later still in France. He died July 23, 1562, in his castle at Hornberg on the Neckar. He wrote an account of his own life, published by Pistorius (Nürn. 1731; Bresl. 1813), which furnishes an excellent picture of the social life and manners of the period, and on which Goethe grounded his drama of *Goetz von Berlichingen*, translated by Sir Walter Scott.

Gouda (Dutch *Ter Gouwe*), a town of South Holland, on the right bank of the Hollaendsche Yssel, 13 miles by rail NE. of Rotterdam. The church of St John has a suite of magnificent stained-glass windows (1560–1603) by the brothers Crabeth and a fine organ. Gouda makes clay-pipes, candles, cigars, and trades in Gouda cheese. Pop. 20,100.

Goudimel, Claude, composer, born at Besançon in 1505, taught music at Rome, composed masses, motets, chansons, harmonised Marot's psalms, and perished at Lyons as a Huguenot, 29th August 1572 (just after St Bartholomew).

Gough, Hugh Gough, Viscount, born at Woodstown in Limerick 3d November 1779, served at the Cape, in the West Indies, and through the Peninsular war, especially distinguishing himself at Talavera and Vittoria. In 1837 he went to India as major-general, and in the following year was made commander-in-chief of the forces sent against China. After storming Canton and forcing the passage of the Yang-tsze-Kiang, he compelled the Chinese to sign the treaty of Nanking (1842). In 1843 he defeated the Mahrattas at Maharajpur, and brought about the peace of Gwalior. On the outbreak of the Sikh war in 1845 he worsted the enemy in the brilliant battles of Mudki, Firozshah, and Sobraon, for which he was given a peerage. In 1848 the Sikhs renewed the war, but were again defeated by Gough at Ramnagar, Chillianwalla, and Gujerat, victories which resulted in the annexation of the Punjab to British India. Gough was in 1849 created a viscount, and about the same time returned to England. He was made field-marshal in 1862, and died near Dublin, 2d March 1869.

Gough, JOHN BARTHOLOMEW, temperance lecturer, was born at Sandgate, Kent, August 22, 1817; his father was a pensioner of the Peninsular war, his mother a village schoolmistress. At the age of twelve he was sent to America, and worked on a farm in Oneida county, New York. In 1831 he went to New York city, where he found employment in the binding department of the Methodist book establishment; but habits of dissipation lost him this employment, and reduced him to that of giving recitations and singing comic songs at low grog-shops. He was married in 1839; but his drunken habits reduced him to poverty and delirium tremens, and probably caused the death of his wife and child. In 1842 a benevolent Quaker induced him to attend a temperance meeting and take the pledge; and soon afterwards, resolving to devote the remainder of his life to the cause of temperance, Gough attended temperance meetings and related his experience with such effect as to influence many others. A few months later he had a short relapse into drunkenness; but an eloquent confession restored him to favour, and he lectured with great pathos, humour, and earnestness in various parts of America. In 1853 he was engaged by the London Temperance League, and lectured for two years in the United Kingdom, where he attracted large crowds to his meetings. He was again in England in 1857–60 and 1878. In some of his later addresses he took up literary and social topics, and acquired a moderate fortune by his lectures. He died at Frankford, Pennsylvania, February 18, 1886. He published an *Autobiography* (1846); *Orations* (1854); *Temperance Address* (1870); *Temperance Lectures* (1879); and *Sunlight and Shadow, or Gleanings from my Life-work* (1880).

Gough, RICHARD, English antiquary, was born in London, 21st October 1735. On leaving Benet (now Corpus Christi) College, Cambridge, in 1756, he began work as a professed antiquarian by a visit to Peterborough and Crowland, and continued to make similar excursions down to 1771. Two years later he commenced the preparation of an English version of Camden's *Britannia*, which was issued in 1789. But three years previously he had published his important *Sepulchral Monuments of Great Britain*, which was brought down only to the end of the 15th century. Amongst numerous minor works from Gough's pen was a *History of the Society of Antiquaries of London* (1770). He died at Enfield, in Middlesex, 20th February 1809.

Goujon, JEAN, the most skilful sculptor of France during the 16th century. The date and place of his birth are not known. The finest productions of his chisel are a figure of 'Diana reclining by a Stag,' now in the Louvre, a remarkably vigorous and graceful work; the reliefs for ornamenting the Fountain of the Innocents, also in the Louvre; the sepulchral monument to the Duke of Breze, in Rouen Cathedral if it is by him executed some time between 1540 and 1552; and several reliefs in the Louvre, where Goujon worked from 1555 to 1562, especially four Caryatides. He was a Huguenot, but seems to have died before the Bartholomew massacre in 1572.

Goulburn, a town of New South Wales, 134 miles SW. of Sydney by rail, with several tanneries, boot and shoe factories, flour-mills, and breweries, and a busy trade in agricultural produce. It is a substantially built town, with gas (1879) and a good supply of water. The seat of an Anglican and of a Roman Catholic bishop, it contains a handsome Church of England cathedral (Gothic, consecrated in 1884) and a Roman Catholic cathedral. It has also a Catholic college and a convent. Pop. 10,916.

Goulburn, EDWARD MEYRICK, D.D., son of Edward Goulburn, serjeant-at-law, was born 1818. He was educated at Eton and Balliol College, Oxford, where he graduated in 1839, and in 1841 was elected a Fellow of Merton. After holding the Oxford incumbency of Holywell, he became head-master of Rugby (1850–58), in succession to Dr Tait. He next became prebendary of St Paul's (1858); chaplain to the Queen, and vicar of St John's, Paddington (1859); and Dean of Norwich (1866), which office he resigned in 1889. In 1872 he led the opposition to Dean Stanley's proposal to make subscription to the Athanasian Creed permissive in the case of ordination. Among his publications are *The Philosophy of Grammar* (1852), *Thoughts on Personal Religion* (1862), and *The Office of the Holy Communion* (1863). He died 3d May 1897. See Life by Berdmore Compton (1899).

Gould. See BARING-GOULD.

Gould, BENJAMIN APTHORP, astronomer, was born in Boston, Massachusetts, 27th September 1824, graduated at Harvard in 1844, and received the degree of Ph.D. at Göttingen in 1848. He conducted the *Astronomical Journal* from 1849 to 1861, was director of the Dudley Observatory at Albany in 1856–59, and in 1866 determined by aid of the submarine cable the difference in longitude between Europe and America. In charge, from 1868, of the national observatory at Cordoba in the Argentine Republic, he organised a series of stations throughout the country, and mapped a large part of the southern heavens: his *Uranometry of the Southern Heavens* did for the southern hemisphere what Argelander's *Atlas* did for the northern. After his return he received the degree of LL.D. from Harvard (1885) and from Columbia (1887). He published valuable astronomical reports and charts, and was a member of numerous scientific societies in Europe. His death, 27th November 1896, was brought about by a fall downstairs.

Gould, JAY, American financier, was born, the son of a farmer, at Roxbury, New York, 27th May 1836. He made a survey of parts of the state, engaged for a short period in lumbering, and accumulated enough capital to become in 1857 the principal shareholder in the bank of Stroudsburg, Pennsylvania. He now began to buy up railroad bonds, and in 1859 established himself as a broker in New York city. He was president of the Erie railway company till 1872, and afterwards invested largely in the stocks of other railways and telegraph companies. In 1882, a question of his commercial stability having arisen, he took the effective step of producing stock certificates having a face value of $53,000,000, and offered to produce $20,000,000 more; in 1887 it was estimated that he controlled over 13,000 miles of railway. He died unlamented, 2d December 1892, worth some $50,000,000.

Gould, JOHN, ornithologist, born at Lyme, Dorsetshire, in 1804. Removing in early life to the neighbourhood of Windsor, where his father was foreman in the Royal Gardens, his ruling passion soon showed itself. He became curator to the Zoological Society's Museum in 1827, when the friendship of Mr N. A. Vigors encouraged him in the production of the first of the large illustrated folios the publication of which from time to time established his reputation. This was a *Century of Birds from the Himalaya Mountains* (1832), the plates being drawn and coloured by his wife. Next after this followed *Monograph of the Ramphastidæ* (Toucans) (1834), *Icones Avium* (1837), *Birds of Europe* (1832–37), and *Monograph of the Trogonidæ* (1838). Assistance was now granted him to proceed to Australia in order to study its natural history; the results of his investigations appeared

in *Birds of Australia* (7 vols. 1840–48), *Mammals of Australia* (1845), and *Family of Kangaroos* (1841–42). His *Monograph of the Odontophorinæ* (American Partridges) appeared in 1844–46, and his *Humming Birds* in 1849. He took immense pains with the illustrations to the latter, the humming-birds, of which he had a splendid collection on view at the Exhibition of 1851, being great favourites with him. Gould's other great works, several of which were left unfinished, were *Birds of Great Britain* (1862), *Birds of Asia*, and *Birds of New Guinea*. Gould, who was a Fellow of the Zoological Society, and contributed largely to its *Proceedings*, helped to prepare the department 'Birds' in the *Zoology of the Voyage of the Beagle*, was a keen sportsman, an accurate observer, and a patient and successful labourer in his chosen field of study. He died 3d February 1881. See *Westminster Review*, 1841, and *Nature*, 1881; and the elaborate *Analytical Index* to his works by R. Bowdler Sharpe (1893).

Gounod, CHARLES FRANÇOIS, an eminent French composer, was born in Paris, 17th June 1818, and studied at the Conservatoire under Halévy, Lesueur, and Paer. Obtaining the first prize in 1839, he was sent to Rome to complete his musical education, and while there devoted himself chiefly to religious music. On his return to Paris he was for a time attached to the church of the Missions Etrangères, where his earliest compositions were performed; one of them, a *Messe Solennelle*, was the first work which brought him into general notice. For a time he contemplated taking orders, and went through part of the preliminary novitiate. His first opera, *Sappho*, was produced in 1851; in 1852 he wrote choruses for Ponsard's drama of *Ulysse;* and in 1854 appeared his opera of *La Nonne Sanglante*. His comic opera, *Le Médecin malgré lui* (1858), was a great success; it was followed in 1859 by *Faust*, which at once attained European popularity, and raised its composer to the foremost rank of contemporary musicians. *Philémon et Baucis* followed in 1860; in 1862, *La Reine de Saba* (brought out afterwards in England as *Irene*); in 1864, *Mireille;* in 1867, *Roméo et Juliette;* in 1878, *Polyeucte;* in 1881, *Le Tribut de Zamora*. He also published much church music, including several masses, hymns, and motets or anthems, and was extensively popular as a song-writer. His oratorio, *The Redemption*, produced at the Birmingham Festival in 1882, and deemed by the composer his masterpiece, has achieved great popularity in Britain, though less esteemed abroad; its sequel, *Mors et Vita*, written for and produced at the succeeding Festival in 1885, has not gained equal approval. From 1870 to 1875 he resided in England, where his works are as much admired as in his own country, his sacred music probably even more. A master of the orchestra, he was the originator of new and impressive combinations. His dramatical faculty is often dominated by the lyric element; he exhibits a singular combination of the mystic and the voluptuous—e.g. sensuous melodies with solemn religious harmonies. *Faust* is generally regarded as his most enduring work. A member of the Institute (1866) and a Commander of the Legion of Honour (1877), he died 18th October 1893. See works by Pagnerre (1890) and Marie Anne de Bovet (1891).

Goura, a genus of beautifully crested ground-loving pigeons, including the largest and perhaps finest members of the family. They inhabit New Guinea and adjacent islands, where they are fond of walking in pheasant-like fashion along the forest paths. They nest on trees and feed on fruits. The first known species, *G. coronatus*, is a beautiful bird over two feet in total length, with the characteristic fan-like crest on the head. It is sometimes kept among poultry, and its flesh is much esteemed.

Gourd (*Cucurbita*), a genus of plants of the natural order Cucurbitaceæ, nearly allied to the cucumber, having male and female flowers on the same plant, the flowers large and yellow. The species are annual plants of very rapid growth, their leaves and stems rough, their leaves broad and lobed, their stems often very long and trailing; they are natives of warm climates, although the native region of the kinds chiefly cultivated is very uncertain, and they have probably been greatly modified by long cultivation, so that perhaps all of them may be forms of one original species, a native of some of the warmer parts of Asia. The Common Gourd or Pumpkin, *Citrouille* of the French (*C. pepo*), with smooth globose or pear-shaped fruit, varying from the size of a large apple to 50 or 100 lb. in weight, is much cultivated both in gardens and fields in almost all parts of the world of which the climate is warm enough for it; and the fruit is not only a very important article of human food, but is also used along with the superabundant shoots for feeding cattle. In many countries pumpkins are a principal part of the ordinary food of the poorer classes, and are much used even by the wealthy; they are not eaten raw, but dressed in a great variety of ways—as in pies, with sugar, spice, &c., or sliced and fried with oil or butter, or made into soups, &c. Pumpkins are much cultivated in North America. In England they are also cultivated, but not to a great extent, and never as food for cattle.—The Vegetable Marrow (*C. ovifera* or *C. succada*) appears to be a mere variety of the pumpkin. It is now more generally cultivated in Britain than any other kind of gourd, being one of the most hardy, and its fruit of excellent quality and useful for culinary purposes at almost every stage of its growth. When full grown the fruit is elliptic, very smooth, generally about 9 inches long and 4 inches in diameter; but there are many varieties distinguished by the form of the fruit and by the delicacy of the texture and flavour of the flesh.—One of the most valuable gourds for culinary purposes is the Great Gourd (*C. maxima*),

The Great Gourd (*Cucurbita maxima*): Branch with flower.

of which the Spanish Gourd is a green-fruited variety; and the Great Yellow Gourd, the largest of all, has yellow fruit, with firm flesh of a deep yellow colour. It is sometimes fully 200 lb. in weight and 8 feet in circumference. The form of the fruit is a somewhat flattened globe; when boiled it is a very pleasant and wholesome article of food. It is much cultivated in the south of

Europe. The French call it *Potiron*, and use it largely in soups.—The Squash (*C. melopepo*) differs from all these in generally forming a bush, instead of sending out long trailing shoots; also in the extremely flattened fruit, the outline of which is generally irregular, and its whole form often so like some kinds of cap that in Germany one variety is commonly known as the *Elector's Hat*, and the name *Turk's Cap* is

Fruit of *Cucurbita maxima*.

bestowed on another. The Squash is regarded as one of the best gourds, and is much cultivated in some parts of Europe and in North America. The Warted Gourd (*C. verrucosa*), which has a very hard-skinned fruit covered with large warts, and the Musk Gourd (*C. moschata*), distinguished by its musky smell, are less hardy than the kinds already named; as is also the Orange Gourd (*C. aurantia*), sometimes cultivated on account of its beautiful orange-like fruit, which, however, although sometimes edible and wholesome, is not unfrequently very unfit for use, on account of colocynth developed in it. This is apt to be the case in some degree with other gourds also, but the bitter taste at once reveals the danger. The same remark is applicable to the young shoots and leaves, which, when perfectly free from bitterness, are an excellent substitute for spinach. In Scotland even the most hardy gourds are generally reared on a hotbed and planted out. In England it has been suggested that railway-banks might be made productive of a great quantity of human food by planting them with gourds. Ripe gourds may be kept for a long time in a cool well-ventilated place, nor are they injured by cutting off portions for use as required. The name gourd is often extended to many other Cucurbitaceæ. See CUCURBITACEÆ, CUCUMBER, &c.; also BOTTLE GOURD.

Gourock, a watering-place of Renfrewshire, on the Firth of Clyde, 3 miles WNW. of Greenock by a railway opened in 1889, since which time it has become the starting-point of several lines of steamers. At Kempoch Point here, behind which rises Barrhill (478 feet), stands 'Granny Kempoch,' a prehistoric monolith associated with the witches of Renfrewshire (1662). In 1688 the first red herring ever cured in Great Britain was cured at Gourock. Pop. (1841) 2169; (1891) 4471. See D. Macrae's *Notes about Gourock* (1880).

Gout (Fr. *goutte*, from Lat. *gutta*, 'a drop'), a medieval term of uncertain date, derived from the humoral pathology (see RHEUMATISM), indicating a well-known form of disease, which occurs for the most part in persons of more or less luxurious habits, and past the middle period of life. In its most common and easily recognised form, it manifests itself by an acute inflammation in the neighbourhood of one of the joints, usually the ball of the great toe; and to such attacks only the name was once applied. But its use is now extended by most writers to include all injurious effects in any part of the body produced by the same condition of the system which leads to the inflammation of the joints. The name podagra (Gr. *pod-*, 'foot,' and *agra*, 'seizure') indicates the leading character of the disease as apprehended by all antiquity; and the very numerous references to the disorder so called, not only in the medical writings of Hippocrates, Galen, Aretæus, Cælius, Aurelianus, and the later Greek physicians, but in such purely literary works as those of Lucian, Seneca, Ovid, and Pliny, show not only the frequency, but the notoriety of the disease. The allusions, indeed, are of a kind which give ample proof that the essential characters of gout have not been changed in the lapse of centuries. It is caricatured by Lucian in his burlesque of *Tragopodagra* in language quite applicable to the disease as now observed; while the connection of it with the advance of luxury in Rome is recognised by Seneca (*Epist.* 95) in the remark that in his day even the women had become gouty, thus setting at naught the authority of physicians, which had asserted the little liability of women to gout. Pliny likewise (book xxvi. chap. 10) remarks upon the increase of gout, even within his own time, not to go back to that of his father and grandfather; he is of opinion, further, that the disease must have been imported, for if it had been native in Italy it would surely have had a Latin name. Ovid and Lucian represent gout as mostly incurable by medicine; from this view of it Pliny dissents. The list of quack remedies given by Lucian is one of the most curious relics of antiquity.

General Causes of Gout.—In more than half the cases gout can be traced to inheritance. There is in fact no disease in which hereditary transmission is more clearly established; in some families its recurrence is notorious. Professor Cantani of Naples even states that in his country 'the hereditary tendency has been handed down from the period of the Greek colonisation and the Roman empire.' Yet even in those strongly predisposed to it its actual occurrence may be avoided by strict regulation of the diet and habits. For, if it is certain that it may be inherited, it is no less certain that it may be acquired, though perhaps not, at all events not readily, by every one; and that the most important of the causes which lead to it are errors in diet. Of these popular opinion has seized upon excessive consumption of alcohol alone; and there is no doubt that alcohol, especially in the form of strong wine or beer, has a powerful effect. But complete abstinence from alcohol will not protect those predisposed to it from the development of gout, unless they are careful with regard to food as well; overeating, especially excessive indulgence in animal food and in rich and highly-seasoned dishes, is no less certain to be prejudicial. Too little exercise, especially when associated with too much food or drink, is also hurtful. Chronic lead-poisoning is frequently associated with the development of gout, though the reason of this is not yet understood. Gout is much more common in the male than in the female sex. It is said to be most common at the present day in England, especially in London, and in southern Italy.

Essential Nature of Gout.—It has long been known that the *tophi* or *chalkstones* deposited under the skin in most well-marked and severe cases of gout consist largely of urate of soda; and that Uric Acid (q.v.) and its salts are often excreted in large amount in the urine of gouty persons. But it was first shown by Dr (now Sir) A. Garrod that this substance is always present in considerable quantity in the blood in cases of gout; in chronic gout at all times, and in acute gout for

some time before the occurrence of an attack. It is now agreed by all that the presence of this substance in excess in the system is an important factor in the production of gout; but authorities differ as to how its presence is to be explained. There are two main theories on the subject which it must suffice to mention: (1) that the processes of disintegration going on in the body, particularly in the liver, lead to its formation in excessive amount; (2) that there is not excessive formation, but defective elimination of it by the kidneys. There is, however, a third theory with regard to the origin of gout, which attributes its occurrence to a perverted condition of the nervous system, and regards the presence in excessive amount of urate of soda in the blood as a subordinate though still important feature of the disease.

Symptoms of Acute 'regular' Gout. Sydenham's treatise on gout, written 200 years ago, is interesting not only as containing the well-considered views of a master in the medical art, but also as the faithful description of the disease by one of the victims of it. His account of the paroxysm of regular gout may be given here with some abbreviation. After some weeks of previous indigestion, attended with flatulent swelling and a feeling of weight, rising to a climax in spasms of the thighs, the patient goes to bed free from pain, and having had rather an unnaturally strong appetite the day before. In the middle of the night he is awakened by a pain in the great toe, or sometimes in the heel, the ankle, or the calf of the leg. The pain resembles that of a dislocated bone, and is accompanied by a sense as if water not perfectly cold were poured over the affected limb; to this succeeds chilliness, with shivering, and a trace of feverishness, these last symptoms diminishing as the pain increases. From hour to hour, until the next evening, the patient suffers every variety of torture in every separate joint of the affected limb; the pain being of a tearing, or crushing, or gnawing character, the tenderness such that even the weight of the bedclothes, or the shaking of the room from a person's walking about in it, is unbearable. The next night is one of tossing and turning, the uneasy limb being constantly moved about to find a better position; till towards morning the victim feels sudden relief, and falls over into a sleep, from which he wakes refreshed, to find the limb swollen; the venous distention usually present in the early stage having been succeeded by a more general form of swelling, often with itching between the toes, and a peeling-off of the cuticle. This individual attack may be repeated many times in the course of what is termed 'a fit of the gout,' which sometimes extends over a period of weeks, or even months, before the patient is completely relieved; or the attacks may occur in both limbs, or in several other parts of the body in succession, the real termination of the 'fit' being at last indicated by an apparently complete restoration of health, and even, in some cases, by a period of improved condition and capacity for exertion, as compared with the state of the patient before the attack.

Such are the principal features of the 'regular gout.' In this form it might almost be called a local disease; although the connection of the attacks with deranged digestion, or with a variety of other minor ailments too complex to be described here, and the obvious relief obtained through the 'fit' from the symptoms of constitutional suffering, point to a cause of the disease operating over a larger range of functions than those included in the ordinary local manifestations at this period. Regular gout, accordingly, forms only part of a nosological picture, in which the so-called irregular, atonic, metastatic, or retrocedent forms have to be included before it can be said to be at all complete. These, indeed, form almost all the darker shadows of the picture; for regular gout, though a very painful disorder, can hardly be said to be dangerous to life, or even to the limb affected, at least until after many attacks.

It is the tendency, however, of gout to fall into irregular forms; and herein lies its danger. One source of local aggravation is, indeed, soon apparent, and it leads rapidly to other evils. The joints which have been repeatedly the seat of the regular paroxysm become, more or less permanently, crippled and distorted. A white, friable, chalk-like material is gradually deposited around the cartilages and ligaments, and sometimes in the cellular tissue and under the skin (tophi or chalk-stones). Sometimes this material is discharged externally by ulceration, and then usually with relief. At other times it accumulates into irregular masses, or 'nodosities,' which entirely destroy, or at least greatly impair, the movement of the limb. The patient is laid up more or less permanently in his arm-chair; and exercise, the great natural specific remedy of the gouty, is denied by the very conditions of the diseased state itself.

Other Manifestations of Gout.—With regard to what should be included under the term *irregular* gout there is much difference of opinion. It is sometimes no doubt used as a refuge for ignorance, when no other cause can be discovered to explain symptoms of ill-health. It is certain, however, that regular gout often alternates with a morbid condition in some other part of the body, and that many diseases occurring in those whose family history or habits of life may be considered to predispose to gout, whether they themselves have suffered from regular gout or not, are benefited by hygienic and medicinal measures similar to those which do good in undoubted cases of gout; and most physicians agree in speaking of such as forms of gout. The most important of these we shall here enumerate, in connection with the organs affected. *Heart and blood-vessels*—palpitation, irregularity of heart action, angina pectoris, and atheroma with its consequence, phlebitis. *Lungs*—asthma, bronchitis. *Nervous system*—neuralgia, headache, epilepsy, mental disorder. *Skin*—eczema. *Digestive organs*—inflammation of throat, various forms of indigestion, cramp or inflammation of stomach, jaundice. *Urinary organs*—irritability of bladder; stone, especially the uric acid form (see CALCULUS); diabetes; above all, chronic Bright's disease. It is impossible within the limits of such an article as the present to give any description of the various manifestations of the gouty tendency; the above list of ailments (most of them treated separately) will give some idea of their complexity and importance.

Treatment of Gout.—The *cure* of gout, in the highest sense of the word, demands the careful consideration of all its predisposing causes in the individual, and the strict regulation of the whole life and habits accordingly, from the earliest possible period. It is the difficulty of accomplishing this which makes gout a disease proverbially intractable; for the regular attacks of the disease seldom occur till pretty late in life, long after the habits have been fully formed which are most adverse to the cure. Rigid temperance in eating and drinking, with daily exercise proportionate to the strength and condition of the individual, in reality constitutes the only radical cure of the gout, the lesson of ages of experience as read to the gouty by the light of science. But the lesson is not learned, or only learned when too late. It should never be forgotten that a man of gouty family, or individually much exposed to the causes of the disease, can only hope to escape it in his old age by habits of life formed at an early period, and by a

careful avoidance of most of the common dissipations of youth. That the disease may be warded off in this way there is ample evidence; and it is not less certain that there is no other way of living secure from gout. The treatment of the fit, in so far as it does not resolve itself into the celebrated prescription of 'patience and flannel,' must be a subject of medical prescription. Blisters, leeches, and especially cold applications, though they may give temporary relief, are studiously to be avoided; the last sometimes even lead to a fatal result. The well-known virtues of Colchicum (q.v.) are perhaps somewhat overrated by the public; and its dangers are not less striking than its virtues. It is certain, however, that in cautious medical hands colchicum is a remedy of great value in the gouty paroxysm; and of equal value perhaps are certain natural mineral waters, as those of Vichy and Carlsbad. Alkalies and their salts, especially potash and lithia waters, as prepared artificially, with minute doses of iodine and bromine, have likewise been much recommended for the cure of gouty deposits. For the distinctions of gout and rheumatism, and the presumed relation between them in some cases, see RHEUMATISM. See Sir Dyce Duckworth's *Treatise on Gout* (1889).

Goutweed. See BISHOPWEED.

Govan, a police-burgh (since 1864) of Lanark and Renfrew shires, on the south bank of the Clyde, outside the municipal boundaries of Glasgow, and about 3 miles west of its centre, but connected with the city by continuous rows of buildings. Its leading industry is shipbuilding. Govan Park, 40 acres in extent, was gifted in 1885 by Mrs Elder, at a cost of £50,000. Pop. (1836) 2122; (1871) 19,200; (1881) 50,492; (1891) 63,364.

Government. The term 'government' signifies the administration of the public affairs of a community; in a secondary sense it denotes the persons to whom that administration is committed, or a select number of such persons in whom the principal powers of management are vested. The domain of government extends in theory over the whole legislative and administrative business of the country at home and abroad; but some departments of our domestic affairs, such as the administration of justice and the business of the permanent civil service, are not treated in practice as matters of government. According to the various uses of the term, we speak of our constitutional government or our system of government by party, or the policy of a particular government, and we draw a distinction, when necessary, between the principal and the subordinate members of the government of the day. There is a distinction in kind between the administration of public affairs and the management of any private concern; but we speak metaphorically of the domestic government of a household; or, with a nearer approach to correctness, of the self-government of municipalities and other civil districts in regard to their local affairs. There may also be small and imperfectly developed communities, whether carried on under a patriarchal rule or under the form of a village-community, or in some other rudimentary form of society, to which it would be difficult to apply the terms of the art or practice of government with anything like exactness. In the case of an ordinary independent state the sphere of government includes the administration of public affairs at home and the intercourse of the community with foreign nations. These functions may be separated and modified, as when a state forms part of a federal union or confederation or combination of states, in which the component communities have divested themselves of some portions of their sovereign power in favour of a central or combined authority, to which certain kinds of public affairs have been delegated. The same remarks apply to dependent and semi-independent states, including such as have been brought under an empire, or have been mediatised, or neutralised, or in any other way have come under the protection or management of a superior power or combination of powers. In colonies the local authorities may be entitled to exercise the rights of government almost as freely as in the case of a protected state, subject only to the reserved rights of the mother-country and the supreme dominion of the home-government, if the necessity for its exercise should occur. There is indeed hardly any limit to the modes in which the relations between superior and subordinate communities may be constituted in matters of government, subject to the observation that the rights conferred on the inferior power may be so great that they practically amount to independence, or may be so closely bound that they give hardly more than the benefits of municipal self-government.

The origin of government may be found in the social instincts of mankind. As soon as a community attains to great numbers, or a large extent of territory, some form of regular authority will be required and will necessarily be established. Plato is accused of having seen no difference in kind between a large household and a small state. Aristotle, or the Aristotelian author of the *Politics*, conceived the state as being 'prior to the individual,' in the sense that it is the true object of the social instinct implanted in all men, and only requiring the legislator's wisdom to bring it to perfection. Every community is established with a view to some good end, and the state (which embraces all other communities) must have been established with the object of attaining the highest good. This theory is nearly identical with the modern opinions, in which a distinction has been made without much real difference, that the state was founded with the object of obtaining the greatest happiness of the greatest number, and that governments are intended to fulfil the higher aspirations of humanity. Many other theories of government have been advanced according to the varying circumstances of different times. It was found convenient in one age to secure a respect for authority by an appeal to the divine right of kings; at another time thinkers have been content to find the principles of government in following the momentary wish of the majority. Hobbes solved the difficulty by a new and arbitrary dogma. Mankind, according to his view, seeking refuge from the dangers of a state of nature, were led, not by any social instinct, but by motives of fear and prudence, to enter into a solemn compact by which they finally renounced the freedom which belonged to the individual man. The compact having once been made, the state becomes the 'Leviathan,' or all-powerful being, to whom absolute and unchanging obedience is due. Locke and many later writers took up the idea of a social contract as a convenient image for describing the combined action of mankind, but guarded their position by declaring that the compact might at any time be altered or reversed.

We may leave these barren speculations as to the origin of government with the remark that, according to the more modern opinion, such questions can only be solved, if at all, by the methods of comparative history. It is of more importance to inquire as to what are the essential characteristics of government in the political sense of the term. In the consideration of this part of the subject the mere forms of government may be disregarded. The correct answer to the problem seems to be that government, in

relation to the subject-matter with which it is concerned, is in the long-run, and continually tends to be, the expression of the will of the dominant power in the state. The expression may be difficult, owing to the complexity of the constitution or the number of constituent parts among which the power is distributed, or owing, as often happens, to the existence of artificial restrictions designed to afford opportunities for delay. Again, the will of the real rulers may be in a state of acquiescence, and the arriving at any decision in favour of change may be impeded in many ways, as by the influence of custom and tradition, the reluctance felt about disturbing an existing delegation of power, or the feeling that responsible and removable governors can safely be trusted. After making all deductions it seems clear that government is in fact an expression of the wishes of those who have the ultimate dominion, and that in free communities its course and even its form are determined by the general will of the people. The forms of government are, however, in some degree determined by accidental circumstances, such as the survival of institutions which have become obsolete, or which have been adapted to existing needs though their original object has come to an end. The possible variations in the form of government are almost countless, but it is still convenient to adopt to some extent the ancient methods of classification, according as the rule of the state is given to the one, the few, or the many. Another method of division is based on the distinction between those states in which the governors and governed have apparently been opposed to each other, and those in which the contest between prerogative and popular liberty has ended in national self-government.

Plato and Aristotle distinguished governments as true or pure when power is given and used for the good of the subject, and as false or perverted when it is maintained for the private interest of the ruler. Among such true forms they counted monarchy or royalty, in which one ruled for the good of all, and aristocracy or the rule of a class, equally acting in the common interest; besides these rare and ideal forms they found another pure form in the mixed or constitutional government, which was the favourite 'polity' of the Greek states when placed under favourable circumstances. It must be remembered, however, that their arguments are made difficult of application to modern times by the facts that the states were very small, and that the great bulk of the population was enslaved; the last circumstance gave a disproportionate importance to the military class, on which the existence of society depended, so that the ancient 'polities' were in practice dominated by an armed middle class, taken collectively as representing the whole people. Hence it was expressly laid down in the Aristotelian *Politics* (lib. iii. chap. 7), that 'in a constitutional government the fighting-men have the supreme power, and the armed men are the citizens.' In the same place will be found an account of the perversions of true government. 'Tyranny,' or despotism, is a monarchy having in view the interest of the master of the state. Oligarchy, of which there are many varieties, exists when a small class, generally consisting of the rich, has the whole government in its power. In Aristotle's view the rule of a wealthy class was of the essence of an oligarchy. Democracy, or the rule of the many, was on the same principle identified with government in the interests of the needy. The author of the *Politics* does not seem to have believed that a wealthy community could be a democracy, or to have conceived the idea of representative government or of a democracy in the modern sense of the term. The democracy described by him was obviously of an unstable and temporary character, ready to suffer a further perversion towards ochlocracy or a mere mob-government, ending in anarchy and the eventual interposition of a despotic or military form of government.

Aristotle distinguished five kinds of monarchy among the true or legitimate systems. The first was the Spartan form, or that which existed in Crete, the power of the kings in each case being strictly limited by the constitution. Next came the despotic form of monarchy, such as was found in the Asian empires, differing only from tyranny because the barbarians, as slaves by nature, were perfectly willing to obey. The third was the Dictatorship, which in Greece was not hereditary, but which has always tended in modern times to become so. Another kind might be called the Heroic form, the kings in ancient times having been 'priests, and judges, and warriors, and having a supreme authority in all things.' Last in the list was the absolute kingship, 'exercising an universal power, like that of the state over the public property, or that of the master over a household' (Arist. *Pol.* iii. chap. 15; Jowett's *Introd.* lxv.). The last-described monarchy is certainly a separate form of government, but it was obviously liable to pass at any moment into a tyranny, unless a succession of disinterested 'benevolent despots' could be found. It should be observed that Aristotle did not think that any monarchy ought to be hereditary, and that he considered absolute monarchy to be contrary to the law of nature. His summary of the causes which had induced the transition from the old kingship to the modern republic is full of interest and information. The reason, he says, why ancient governments were monarchies is that in early times there were only a few good men who could confer benefits, and so they were made into kings. The reason, he adds, why democracies are now necessary is that all men are 'pretty much on an equality;' he is referring, of course, to the freemen who had the franchise and a capacity for office. 'When good men increased in number, royalties passed into aristocracies. These degenerated into oligarchies. Oligarchy passed into "tyranny," and tyrannies became democracies, for the rich became fewer and fewer, and the poor more and more numerous; and democracy seems to be the only form of government any longer possible, now that cities are increased in size.' He shows, however, his personal preference for the mixed constitution or 'polity,' as probably the best form of government after the ideal 'rule of the best,' or 'aristocracy' in the highest sense of the term. The stages through which oligarchy usually passed are summed up as follows: at first there is a high qualification for office, and then as vacancies in office occur, a scheme of co-optation is devised: afterwards hereditary succession is introduced, and finally a few powerful families set up an absolute and arbitrary rule. Democracy in the same way has several stages from that in which all men are equal in circumstances and power, if such an 'Utopian parity' were possible, to the stages when a small qualification is imposed, when every one takes a share in the government, and lastly, when law ceases and the government is carried on by the decrees of the transient majority.

Plato constructed an ideal state, an aristocracy in which philosophers were kings, and thought that of inferior governments there were only four worthy of notice, though, doubtless, there were many intermediate forms both among Greeks and barbarians. He calls the first Timocracy, being a constitution of the fashionable Spartan type, in which the powers of the kings and classes of citizens were limited by strict discipline, and the government was conducted on 'principles of honour,'

which in practice came to something like military government. It should be observed that the word 'timocracy' is also used to denote the system of distributing honours and offices according to wealth, a state of things to which the title of a plutocracy would perhaps be more appropriate. Next in Plato's list came Oligarchy, with its attendant evils of avarice and corruption; then Democracy, described as 'a pleasing lawless and various kind of government;' and lastly, Despotism, the 'disease and death of government.' Polybius (book vi. extr. 3, chap. 1) mentions the states of Lacedæmon, Mantinea, Crete, and Carthage as those which were praised by all writers of antiquity. He differs from Plato as to the fact of resemblance between the governments of Crete and Sparta, not perceiving that they were alike in their balance of power, though their laws and institutions were different. The laws of Lycurgus appeared to him to be rather the 'work of some divinity' than the effort of a human mind. The government of Carthage was praised as being limited in much the same way, the king, senate, and people all having a share of power; but his highest commendation was reserved for the Roman Republic. Of this he has left an interesting account, of which Cicero afterwards made considerable use in his treatise *De Republicâ*.

Passing to modern times, we find that the existing kinds of government are still in many cases much influenced by traditions of the empire, and to some extent by the usages of feudalism. The autocratic form of government still survives, though the ruler's apparently absolute power is generally limited by a 'bureaucracy.' In the greater part of Europe we find constitutional monarchies, in which the powers of the crown and the various classes in the community are supposed to be balanced against each other. The tendency of most of these limited monarchies is apparently towards democracy. The democratic republic has been most successful in the United States of America and in the old-established Swiss Confederation. We have also seen the establishment of empires of a medieval type, as well as governments founded on a principle called Cæsarism, in which a democracy is supposed to have delegated its powers to a dictator. Various circumstances have led to the formation of dual and complex monarchies, and to the placing of various communities in dependent and subordinate positions. The most important feature in modern governments is the extension of the representative system, which can be best studied in the history of Great Britain, justly praised as the 'Mother of Parliaments.' Mr Mill's work on *Representative Government* should be consulted on the question whether our modern societies ought to make provision for protecting the minority. The problems of government are continually changing, and new remedies will be required as fresh difficulties arise, but the main object of all governments, under whatever forms they exist, must be the fulfilment of the laws and the preservation of order and liberty.

What is the best form of government is a question which every one will answer according to his own disposition, if a specific answer can be given without reference to the varying circumstances of states and communities. Some aid in the matter may be obtained by the study not only of treatises dealing directly with the art of government, but also of political satires and the numerous writings upon the ideal state and the first principles of society. Among these may be mentioned the *Utopia* of Sir Thomas More, the *De Monarchiâ* of Dante, the sketch of a new government in Burton's *Anatomy of Melancholy*, Harrington's *Oceana*, and Lord Bacon's *New Atlantis*, besides Dr Jowett's Introductions to the *Republic* and *Politics*, and the other treatises upon the subject which have already been mentioned.

Among the multitude of modern writings which deal with the abstract principles of government particular notice is due to Sir G. C. Lewis's treatises on the *Best Forms of Government* and the *Methods of Observation and Reasoning in Politics*. Mr Herbert Spencer's works on *Social Statics* and the *Principles of Sociology*; Humboldt on the *Sphere and Duties of Government*, and Guizot's *Histoire des Origines du Gouvernement Représentatif en Europe*. Among the treatises which deal with the growth of governments by the methods of comparative history Sir H. S. Maine's work on *Early Institutions* is one of the most important. A general view of the rise of the governments of Europe is to be found in Mr Hallam's *View of the State of Europe during the Middle Ages*, with which should be compared Guizot's *Histoire Générale de la Civilisation en Europe*. With respect to the growth of the British constitution the reader should refer to the general essays and histories of Hume, Macaulay, and Freeman, and for more special information to the constitutional histories of England by Mr Hallam and Dr Stubbs, Earl Russell's *English Government and Constitution*, Earl Grey's *Parliamentary Government*, and Bagehot's essay on the English Constitution. On the important subject of political institutions in America the fullest information may be found in Storer's *Commentary on the Constitution of the United States*, and in the valuable work of Professor Bryce on the *American Commonwealth*. See the articles ARISTOCRACY, AUTOCRACY, CABINET, CENTRALISATION, CIVIL SERVICE, COMMUNISM, CONGRESS, DEMOCRACY, LOCAL GOVERNMENT, OLIGARCHY, PARLIAMENT, PRIVY COUNCIL, SOCIALISM, &c.

Governor, the supreme executive magistrate of a state or colony. The varying functions of governors, governors-general, and lieutenant-governors are explained in the articles UNITED STATES, INDIA, &c. For the governor of a steam-engine, see STEAM-ENGINE.

Gow, NEIL, a famous Scotch violin player, was born at Inver, near Dunkeld, 22d March 1727, and before he reached manhood had become the best performer of reels and strathspeys in Perthshire. Through the notice of the Duke of Athole, with whom he was a life-long favourite, he was introduced to the patronage of the principal nobility and gentry throughout Scotland; and such was the kindly esteem in which he was held that Sir Henry Raeburn was several times employed to paint his portrait for his patrons. He died 1st March 1807. Gow composed nearly a hundred tunes, mostly of a lively character; but it is chiefly to the tradition of his singular skill with the bow that his name owes its survival almost as a household word in Scotland.—His youngest son, NATHANIEL, born 28th May 1766, was trained as a violin-player in Edinburgh, where in 1782 he became one of the king's trumpeters for Scotland, and subsequently was leader of a fashionable band, and a successful teacher. His first venture as a musicseller (1796–1813) was not successful, and a second attempt ended in bankruptcy in 1827; but his admirers came to his aid, and his few remaining years, though darkened by sickness, were not distressed by actual want. He died 17th January 1831. He published numerous and very full collections of Scotch airs and songs; and his own compositions number over two hundred—among them 'Caller Herring.'

Gower, part of Glamorganshire (q.v.).

Gower, JOHN, English poet, was born probably about 1330, and seems to have belonged to a family that owned land both in Suffolk and in Kent. But little is known of his life save that he was rich and well educated, did not marry till late in life (probably in 1397), became blind about 1400, and died in the later half of 1408. His tomb is still to be seen in St Saviour's, Southwark. He was a personal friend of Chaucer, who, in dedicating to

him his *Troilus and Cressida*, addresses him as the 'moral Gower'—an epithet that has indissolubly linked itself with his name. Near the conclusion of the *Confessio Amantis* Gower makes Venus in some copies pay a warm compliment to Chaucer as her 'disciple and poet,' which is followed immediately by lines expressing warm loyalty towards Richard II. Both these passages are omitted in the copy dedicated to Henry of Lancaster, then Earl of Derby (afterwards Henry IV.), which appeared at a time when Chaucer was in trouble with the government, and this fact, taken in conjunction with Chaucer's expressed dislike (Introduction to the Man of Lawes prologue) to a certain kind of sensational stories—of 'unkynde ('unnatural') abhominaciouns,' which he exemplifies by the stories of Canace and Apollinus of Tyre—two of the best told tales interspersed in the *Confessio Amantis*—led Tyrwhitt to the conjecture that the friendship between the two poets was interrupted in their old age. But in this there is really no ground for any inference further than that Gower was merely a timid and time-serving man; while the conjecture is completely demolished by the discovery that Chaucer's poem was written first (before 1385), and by the fact that Chaucer took the substance of the Man of Lawes Tale direct from Nicholas Trivet's French prose chronicle of the Life of Constance (written about 1334), and not indirectly through Gower's version of the same, as was supposed by Tyrwhitt, Wright, and most scholars down to the appearance of Mr Brock's English translation of Trivet in *Originals and Analogues of some of Chaucer's Canterbury Tales*, published for the Chaucer Society (1872–75).

Gower wrote three large works in three languages, the *Speculum Meditantis*, in French verse, rediscovered at Cambridge in 1896; the *Vox Clamantis*, a tedious Latin elegiac poem, written 1382–84, describing Wat Tyler's rebellion in 1381, full of dreary allegorising and moralisation (edited by Rev. H. O. Coxe, Roxburghe Club, 1850); and the long poem entitled *Confessio Amantis*, written 'in our English . . . for England's sake,' of which the date is uncertain, but it must have been in existence in 1392–93. In a passage in the earlier edition of the last work, dedicated to Richard II., he tells us how he met the king's barge one day when rowing down the Thames at London, and how the king invited him on board, and commanded him to write a book upon some new matter. There are extant also fifty French ballads, written by Gower in his youth (Roxburghe Club, 1818).

Gower's *Confessio Amantis* consists of a prologue and eight books, written in verses of eight syllables, rhyming in pairs. The long prologue gives a sombre account of the state of the world at that time, and the poem opens by introducing the author himself in the character of an unhappy lover. Venus then appears to him, and appoints her priest called Genius to hear the lover's confession of all the sins he has committed against love. Under each several head the confessor consoles him and gives him warning by relating apposite stories of the fatal effects of each passion in the experiences of former lovers in like case. It ends with the lover's petition in a strophic poem addressed to Venus, her judgment, and finally the lover's cure and absolution. The stories inserted are taken from Ovid's *Metamorphoses*, the *Gesta Romanorum*, the medieval histories of Troy and Alexander the Great, from the *Pantheon* and *Speculum Regum* of Godfrey of Viterbo, the romance of Sir Lancelot, and the Chronicles of Cassiodorus and Isidorus. The mixture of Ovidian and Christian morality is often incongruous enough, and the whole poem is dull and prolix to the last degree. Without originality, narrative power, pathos, or humour, Gower yet commands respect for the laborious equality of his verse, and his work remains a splendid monument of English. Mr Lowell is too severe upon his uniformity of commonplace, his omnipresent tediousness, his imperturbable narrative, the tremendous hydraulic power of his allegory to squeeze out all feeling and freshness, the frozen levels of his verse, and the inevitable recurrence of his rhyme regularly pertinacious as the tick of an eight-day clock; although indeed it cannot altogether be denied that 'he has positively raised tediousness to the precision of science, and has made dullness an heirloom for the students of our literary history.' The best editions are by Dr Reinhold Pauli (3 vols. Lond. 1857) and G. C. Macaulay (4 vols. 1899-1901, vol. i. giving Gower's works in French).

Gown, a loose upper garment worn by members of universities, civil magistrates, and the like. The use of the gown by ecclesiastics has been erroneously derived from the custom of the friars, but is more probably to be traced to the practice of inviting doctors of divinity to preach, and to the power of the university to license graduate preachers. Originally the gown was merely the out-of-door dress; and after the Reformation the clergy (mostly Puritan) who did not hold degrees, regarding enviously the comely wide-sleeved gown which was the mark of the graduate, adopted a gown of their own or of Genevan devising. In 1444 all doctors and graduates of the Benedictine order were authorised to use their scholastic habit when preaching before a large congregation; and in 1571 the gown formed part of the preacher's 'common apparel abrode.' Addison, in the *Spectator* (1714), speaks of the clergy 'equipped with a gown and a cassock;' and both garments were retained until within the 19th century. In Edinburgh, at the coronation of Charles I., the Archbishop of Glasgow and others not engaged in the service 'changed not their habit, but wore their black gowns without rochets or sleeves;' but in the same year a warrant was sent down from London, directing the use of the 'whites' by bishops and archbishops, and ordering all inferior clergymen to preach in their black gowns, but to use their surplices while reading the prayers and in other services. In the 18th century, however, even during the service, the surplice was almost unknown in the Scottish Episcopal Church. The controversy in the Anglican Church as to exchanging the surplice for the gown in preaching, which arose about 1840 and exercised the church for a generation, has never received a definitive settlement.

The academic gown is a survival of the *tabardus*, a garment with many folds, which came in when the doctors began to wear long, priestly robes as a distinctive mark of their standing as clerics. At Padua, for instance, certainly as early as the 16th century, the gown and square cap were the insignia of a doctor; and, at a later period, the undergraduate of Trinity College, Cambridge, wore a gown of violet colour to distinguish him from the doctors, who wore a scarlet gown. The purple gown common to all rectors of universities has been described as the livery of the popes: in the words of the Emperor Joseph II., it is a reminiscence of 'the dark times when the papal see arrogated to itself the exclusive right of establishing universities.' On the Continent the several faculties possess distinctive colours, although in some universities, as at Leipzig and Tübingen, only two colours have been used. In Britain a similar custom obtains in the full dress of doctors; the faculty, like the university, of a graduate is indicated by his hood. The gowns of under-graduates are now black, except at Glasgow, Aberdeen, and

St Andrews; but in some of the English universities surplices are worn in college chapel on Sundays and saints' days. University preachers in England wear academic gowns. In the United States there is no distinctive academic dress. See *Notes and Queries*, 5th series, vol. xi.; and a paper in Prof. Delitzsch's *Iris* (Eng. trans. 1889).

Gowrie, CURSE OF. See PERTHSHIRE.

Gowrie Conspiracy is the name given to one of the most singular episodes in the history of Scotland, although the very existence of a plot is still a matter of controversy. As set forth by James VI., the details of the conspiracy are as follows. Early in the morning, on Tuesday, 5th August 1600, as his majesty was about to begin a stag-hunt in Falkland Park, Fife, Alexander Ruthven came to him with the information that, as he was walking alone near Perth, on the previous evening, he had met and seized an individual of suspicious appearance, with a pot full of foreign gold hidden under his cloak. After having confined him in 'a privy derned house,' he had hastened to Falkland to lay the matter before the king, and to request him to ride over to Perth for the purpose of taking possession of the treasure, and of examining the mysterious stranger. Though at first disinclined to believe the 'uncouth' story, James was ultimately induced, by the thought that the foreign money might betoken an agent of the pope and the Jesuits, to promise that he would accompany Ruthven to Perth. This he did at the close of the hunt, not waiting to change his horse, and riding at such speed that his attendants, amongst whom were the Duke of Lennox and the Earl of Mar, did not overtake him till within a short distance of the city. At Perth he was received by Ruthven's brother, the Earl of Gowrie, in such a manner as to make it appear that the visit was wholly unexpected, and kept waiting a long time before any refreshment was offered him. After his own dinner, and whilst the gentlemen of his retinue were still at table, James was taken by Ruthven through several rooms to a small study, which was situated on the first story, and of which one of the windows overlooked the courtyard of Gowrie House and the other a public street. On crossing the threshold the king beheld 'not a bound man, but a free man, with a dagger at his girdle.' At this moment Ruthven, having locked the door, snatched the armed man's dagger and held the point to the king's breast, telling him that he was now a prisoner, swearing many bloody oaths that if he cried or made any attempt to open a window the dagger would go to his heart, and, further, reproaching him with the murder of the first Earl of Gowrie, who had been executed for treason in 1584. At this James began to expostulate with Ruthven, who so far relented as to leave the king in the armed man's keeping, while he himself went out to consult his brother, the earl. During his absence James questioned the armed man, who protested that he had been thrust into the room without knowing for what purpose, and who willingly obeyed the order to open one of the windows, the king himself, scrupulously faithful to a promise extorted from him by Ruthven, being unwilling to do so. In a few moments Alexander returned, and, declaring that there was no help but that the king must die, produced a garter with which he attempted to bind his hands. A fierce struggle ensued, during which the armed man stood behind the king's back, 'doing nothing but trembling all the time,' and of which the result was that James was able to reach the open window and to call for help. Whilst this was going on in the study, a servant of the household had entered the hall where Gowrie still was with Lennox, Mar, and the other courtiers, and informed him that the king had ridden off to Falkland. At this the whole company hastily rose to follow, and had reached the street when the king's cries were heard. Lennox, Mar, and the other attendants at once turned back and made for the upper story by way of the main staircase, but were prevented by a barred door from reaching the king. John Ramsay, a royal retainer, had also heard his master's voice, and, finding a door open at the foot of the turret, at once entered and ran up the winding stairs. They led directly to the study, of which Ruthven had forgotten to close the entrance, and in which the hand-to-hand struggle was still going on. Drawing his hunting-knife Ramsay twice stabbed the king's antagonist, who, loosing his hold, was thrust down the stairs by James and despatched by Sir Thomas Erskine and Dr Herries, who were at that moment coming up; his last words were 'Alas, I had na wyte (blame) of it.' Scarcely had this taken place when the Earl of Gowrie appeared on the scene, bearing a drawn sword in each hand, and followed by seven of his servants. A short encounter ended with the death of the earl, who expired without uttering a word. The inhabitants of Perth, by whom Gowrie, who was their provost, was much beloved, hearing of his fate, surrounded the house and threatened revenge. But after the king had addressed them from a window, and admitted the magistrates, to whom he related the circumstances, they quietly dispersed, and James was able to return to Falkland. On the authority of the king's declaration Gowrie and Ruthven, whose dead bodies were produced at the bar, were declared traitors, and three of their servants were hanged. On the other hand, marks of royal favour were bestowed on all who had come to the king's assistance in the study. Ramsay was knighted, and subsequently created Viscount of Haddington and Earl of Holderness; Sir Thomas Erskine was raised to the peerage as Lord Dirleton, and Dr Herries received the honour of knighthood as Sir Hugh Herries of Cowsland. Henderson, the 'armed man,' after having obtained a free pardon, was rewarded with a gift of lands and a large pension.

To the events of 1600 there was a sequel a few years later. In 1608 George Sprott, a notary in Eyemouth, was apprehended, condemned, and executed for being privy to a conspiracy between Gowrie and Robert Logan of Restalrig. He confessed to having seen several letters written by Logan to the earl, and to having retained one of them, but no document of the kind alluded to was actually put in at the trial. Next year, however, there were produced five letters, said to have been discovered amongst Sprott's papers, and alleged to contain proof of a plot to kidnap the king. On the strength of them Logan, who had died in the meantime, but whose mouldering bones were dug up and brought to trial, was declared to have been guilty of high-treason. From the very first the story of the conspiracy was received with incredulity by many in Scotland, and amongst these by the clergy of Edinburgh, with Robert Bruce at their head, and by the queen herself; whilst the Duke of Lennox, though he had appeared as one of the chief witnesses at the trial, asserted that 'if it were given to him to his oath, he could not say whether the practice proceeded from Gowrie or the king.' In England Elizabeth, on being informed by a special messenger of what had taken place, gave him to understand that she 'did not believe Gowrie and his brother to be so guilty as they were represented.' In France James's statement was openly ridiculed. This attitude of scepticism is still

maintained by some writers, who point out that, with the exception of Burton's general remark that 'seizing upon or kidnapping a king had in that day become almost a constitutional method of effecting a change of ministry in Scotland,' nothing has ever been urged to prove that either Gowrie or Ruthven could benefit by the king's murder or captivity, whilst by the death of the earl and his brother James was freed from a debt of over £80,000, and rid of a political opponent in the person of the one, and possibly of a rival in the queen's affection in that of the other; that, whilst there is no trustworthy evidence to prove the interview in Falkland Park to have been of Ruthven's seeking, the king very shortly before had sent letters to both the brothers; that, whilst the reason alleged by the king to account for his visit to Gowrie House is palpably absurd, that given by Ruthven, who ascribed it to the matter of the debt, is reasonable; that the point which tells most against Gowrie—viz. his conduct on receiving the false information of James's departure for Falkland—is not inconsistent with innocence; that the position of the study to which the king was taken makes it incredible that it could have been selected for a criminal purpose; that in his various statements Henderson, who was produced as being, but was not generally believed to have been, the 'armed man,' contradicted not only the king and Ramsay, but himself as well; that Ruthven's dying exclamation, 'Alas, I had na wyte (blame) of it,' may reasonably be looked upon as referring to the origin of his struggle with the king; that Sprott, whose confession was the only evidence connecting Gowrie and Restalrig, was looked on as a madman by the king's warmest sympathisers; that the famous letters were not produced at his trial; that in the following year they did not at first convince the jury, who brought in a verdict of guilty against Logan only after they had been remonstrated with by the Earl of Dunbar; and, finally, that those letters bristle with discrepancies, contain no proof of a plot for the abduction of the king, whom they do not even mention, and cannot, from their dates, be made to refer to any event intended to take place till long after the 5th of August. There is yet another view adopted by those who, whilst admitting the innocence of Gowrie and Ruthven, find it difficult to believe that the king devised a plot in which he was himself to play a dangerous part. It is in substance the same as that set forth at the time by Sir William Bowes, the English agent in Edinburgh, in a letter to Sir John Stanhope. It is to the effect that there was no conspiracy on either side, but that the struggle in the study arose out of some sharp words that passed between the king and Ruthven concerning the execution of the latter's father, and that all the subsequent events were in part contrived, in part utilised, for the purpose of giving James's conduct what Bowes calls 'an honourable cloak.' See Louis A. Barbé's *Tragedy of Gowrie House* (Paisley, 1887).

Goyana, a town of Brazil, 40 miles N. by W. of Pernambuco, with a large Carmelite monastery, and flourishing sugar-plantations. Pop. 10,000.

Goya y Lucientes, Francisco, the most distinguished painter of the new Spanish school, was born at Fuente de Todos, in Aragon, 30th March 1746, and received his first education in art in the academy at San Luis, Saragossa. On his return from a visit to Rome, the talent and speed with which he executed some paintings for the royal tapestry manufactory gained the approbation of the celebrated Mengs, who superintended that work. His scenes from the common life of the Spanish people excited special admiration. In 1780 he was elected member of the academy of San Fernando. From this time, although he remains in all his work a thorough Spaniard, the influence of Velasquez and Rembrandt is observable in his paintings. Among the most celebrated of these is his portrait of Charles IV., for which he was made court-painter. In 1824 he went to Paris for his health, and continued to reside in France till his death at Bordeaux, 16th April 1828. See Lives by Yriarte (1867), Lefort (1877), De la Viñaza (1887), and Rothenstein (Lond. 1900).

Goyaz, the central province of Brazil, falls within the dry plateau region, rising in the south to an important range of mountains (see Brazil), and has an area of 287,430 sq. m. The river Tocantins traverses most of the province from south to north, and receives the Araguay, which forms the western boundary; the southern frontier is marked by the Paranahyba. The climate in the south is healthy, but in the north malignant fevers are common, and the cattle are subject to goitre. The province had once some fame as a source of gold and diamonds; but these products are exhausted, and its deposits of iron and rock-salt are not worked. Stock-raising is the chief industry, the cattlemen being mostly half-civilised *vaqueiros*. The population was estimated in 1895 at 230,000, mostly half-castes. There are also several thousand wild Indians.—The capital, Goyaz, on the Vermelho, a tributary of the Araguay, preserves in its cathedral and large government buildings traces of better days. Pop. 8000.

Gozo (called by the Romans *Gaulus*), an island in the Mediterranean, lying 4 miles NW. of Malta and belonging to Britain, has, with the adjacent smaller island of Comino, an area of 20 sq. m. and a pop. (1891) of 16,500. The surface is hilly, but the soil is fertile. The chief town is Babato, situated near the centre of the island. The history of Gozo is identical with that of Malta (q.v.).

Gozzi, Count Carlo, Italian dramatist, was born at Venice in March 1722. The publication of several slight but witty and satirical pieces made him known in his native city, and the part he took in combating the theatrical innovations of Chiari and Goldoni made him famous. For the purpose of counteracting the attempts of these two writers to free the Italian stage from the puerilities of the Commedia dell' Arte by the introduction of translations of newer French dramatic works, Gozzi wrote a satirical poem, *Tartana degl' Influssi per l'Anno Bisestile* (1757), and a comedy, *Fiaba dell' Amore delle tre Melarancie* (1761). In this last work he struck a vein which for a time proved to be extremely popular, and he wrote several similar 'dramatic fairy-tales,' as he called them, the best being *L'Augellino Bel Verde*. But the best known, from Schiller's translation of it, is *Turandot*, which Gozzi himself borrowed from a Persian source (Nizami). His latest dramas were modelled upon those of Calderon, but they enjoyed only a moderate success. Gozzi died 4th April 1806. In 1772-74 he edited a complete collection of his own works in 10 vols.; but a fuller edition came out at Venice in 14 vols. in 1802. See his Memoirs (1797; Eng. trans. by J. A. Symonds, 2 vols. 1889).—His brother, Count Gasparo Gozzi, was born at Venice, 20th December 1713. His first attempts in literature, the translation of dramas from the French for production in the theatre of Sant' Angelo at Venice, were not successful. But his next ventures, the editing of two journals, *Gazzetta Veneta* (from 1760) and *Osservatore Veneto* (from 1761), to which he contributed very copiously, established his fame as one of the most elegant writers of literary Italian. The second of these works was an attempt to

imitate the English *Spectator*. For some time Gozzi was press censor in Venice. He died at Padua, 26th December 1786. Besides the works named he also wrote *Il Mondo Morale* (1760), a collection of essays; *Lettere Famigliari* (1755); and *Giudizio degli Antichi Poeti sopra la Moderna Censura di Dante* (1758), a defence of the king of Italian poets against the strictures of Bettinelli. Collected editions of his works were published at Venice (12 vols. 1794–98, and 22 vols. 1812).

Gozzoli, Benozzo (properly Benozzo di Lese), an Italian fresco painter, a pupil of Fra Angelico, was born at Florence about 1420. At Montefalco (1450–52) he painted the 'Virgin giving her Girdle to St Thomas' in S. Fortunato, and a series of frescoes illustrating the life of St Francis, an Annunciation, and a Crucifixion, in the monastery of S. Francesco. At Florence (1456–64) he adorned the Palazzo Riccardi with scriptural subjects, and painted various similar frescoes at San Gemignano (1464–67). His name is likewise intimately associated with a series of twenty-four fine frescoes in the Campo Santo or cemetery at Pisa (1468–84). He died at Pisa in 1498. His works show great individuality of treatment, true landscape feeling, and something of the naturalistic tendencies of Fra Filippo. See an article by Stillman in the *Century* for November 1889.

Graaf, Regnier de, a Dutch physician and anatomist, was born at Schoonhoven, 30th July 1641, studied at Leyden under Dubois (De le Boé), better known as Sylvius, and afterwards in France, taking the degree of doctor of medicine at Angers in 1665. The year after he settled at Delft, where he practised until his death, 17th August 1673. In 1663 he wrote *Disputatio Medica de Natura et Usu Succi Pancreatici*, which gained him a great reputation. In the course of his investigations in abdominal anatomy he discovered, in 1672, the Graafian vesicles or follicles of the female ovum (see Ovary). He wrote several dissertations on the organs of generation in both sexes, which involved him in a prolonged and angry controversy with Swammerdam. His *Opera Omnia* were published at Leyden in 1677, and republished in 1686 and 1705.

Graafian Vesicles. See Ovariotomy.

Graaf-Reinet, a town of Cape Colony, nearly girdled by the Sunday River, 185 miles N. of Port Elizabeth by rail. Founded in 1784, it still preserves the quaint and simple characteristics of the old Dutch town; and with its vineyards, orchards, and gardens, in contrast to the burning karroo plains that encircle it, it has been well called 'the gem of the desert.' The streets are wide, with rows of oak, orange, and other trees, and broad channels of running water; the houses white, with overhanging thatches and broad 'stoeps.' Behind it the Sneeuwberg Mountains rise to a height of 1000 to 1500 feet. Pop. 6000.—The division of the same name has an area of 3792 sq. m., and a population of about 17,000.

Gracchus, the name of a Roman family, of the gens Sempronia, which contributed several famous citizens to the state: (1) Tiberius Sempronius, a distinguished opponent of Hannibal in the second Punic war, who fell in battle against Mago, 212 B.C., and was honoured by Hannibal with a splendid funeral. (2) Tiberius Sempronius, the father of the two tribunes whose fame has overshadowed all the others. He was born about 210 B.C., filled successively all the high offices of state, conquered the Celtiberi, and by his kindly treatment of the Spaniards earned their lasting gratitude. He married Cornelia, the youngest daughter of P. Scipio Africanus, who bore him twelve children, of whom all died in youth save a daughter, Cornelia, who married P. Scipio Africanus the younger, and the two illustrious sons whose history follows.

Tiberius Sempronius Gracchus was born about 168 B.C., and was educated with great care by his excellent mother, his father having died while he was yet very young. He was already a distinguished soldier when in 137 he served as quæstor to the army of the consul Mancinus in Spain, where the remembrance of his father's honour, after forty years, enabled him to gain better terms for the 20,000 Roman soldiers who lay at the mercy of the Numantines. But the peace was repudiated at Rome, and Mancinus was stripped naked and sent back to the Numantines, as if in that way the treaty could be rendered void. The hopeless poverty in which thousands of the Roman citizens were sunk now began to weigh upon the mind of Gracchus, and ere long he plunged into an agitation for reform to which he was soon to sacrifice his life. Elected tribune of the people in 133, he endeavoured to reimpose the agrarian law of Licinius Stolo, and after violent opposition on the part of the aristocratic party, who had bribed his colleague M. Octavius Cæcina, he succeeded in passing a bill to that effect. Tiberius Gracchus, his brother Caius, and his father-in-law Appius Claudius were appointed triumvirs to enforce its provisions. Meantime Attalus, king of Pergamus, died, and bequeathed all his wealth to the Roman people. Gracchus therefore proposed that this should be divided among the poor, to enable them to procure agricultural implements and to stock their newly-acquired farms. It is said that he also intended to extend the franchise, and to receive Italian allies as Roman citizens. But fortune turned against the good tribune. He was accused of having violated the sacred character of the tribuneship by the deposition of Cæcina, and thousands of the fickle mob deserted their champion and benefactor. The selfish and unscrupulous aristocrats formed a ring for his destruction, a bad eminence in which belonged to P. Corn. Scipio Nasica. In the midst of the next election for the tribuneship Tiberius Gracchus with some hundreds of his friends was foully murdered.

Caius Sempronius Gracchus was nine years younger than his brother, and had greater natural powers and wider aims. His brother's death occurred while he was serving in Spain under Scipio Africanus, and deterred him for some years from entering into public life, but at length he unexpectedly returned to Rome, urged by his brother's shade to take up his mission. He stood for the tribuneship, and was elected in 123, and a second time the year after. His first measure was to renew his brother's agrarian law, which had by the machinations of the nobles been kept in abeyance. With passionate earnestness he devoted himself to the cause of the poor, whose immediate misery he relieved by employing them upon new roads throughout all parts of Italy. But not all his noble devotion to the real good of Rome could save him from his brother's fate. By an intrigue of the senatorial party his colleague M. Livius Drusus was bribed to undermine the influence of Caius by far surpassing him in the liberality of his public measures, and by his benefits to the commons, and consequently Caius was rejected from a third tribuneship. At the expiry of his term the senate began to repeal his enactments. Caius appearing in the Forum to make opposition, a fearful riot ensued, in which it is said as many as 3000 of his partisans were slain. Caius held aloof from the fight, but was at length compelled to seek safety in flight. He escaped to the grove of the Furies with a single slave, who first slew his master and then himself. The people

saw too late the folly of which they had been guilty in abandoning their best friend in the hour of need, and endeavoured to atone for their crime by erecting statues to the two brothers, by declaring sacred the spots where their blood had been shed, and by offering sacrifices to them as to deities. Their mother survived them long, and upon her tomb the Roman people inscribed the words, 'Cornelia, mother of the Gracchi.' See the articles AGRARIAN LAWS and ROME.

Grace, in theology, is general or special.—*Common* or *general* grace denotes the love which God has to all his creatures, and the light of nature and of conscience which they all enjoy. *Special* or *particular* grace is the love which God has for his elect people, and by which he saves them from their sins. Special or saving grace is spoken of as electing, justifying, sanctifying grace; also as *imputed* grace—the grace of Christ's righteousness imputed to those that believe on him. Grace is further efficacious and irresistible; and elect or believing people are said to stand to God in the covenant of grace, Adam's relation to his Maker before the fall being the covenant of works. When man is said to be in a state of *grace*, it implies that he is in the enjoyment of this divine love and favour. St Paul draws a sharp contrast (Rom. xi.) between 'grace' and 'works.'

Grace at Meals was the custom of the Jews; and Our Lord 'blessed' or 'gave thanks' before distributing the loaves and fishes, and again before and after the Last Supper. That it was the general practice of the early Christians to give thanks, seemingly at every meal, is evident from the writings of St Paul and of the Fathers. The Gelasian Sacramentary (end of 5th century) contains probably the most ancient graces of the Latin Church now extant. At Clifford's Inn the 'acted grace' consisted in the raising three times, in allusion to the Trinity, of four loaves, representing the four gospels, which the president then propelled along the polished tables to the vice-chairman, to symbolise the spread of the gospel to the heathen. The canon *Non Nobis, Domine* by William Byrd (q.v.) is often sung in England at public dinners in place of a grace after meat. The old college grace, 'Benedictus benedicat,' and, after dinner, 'Benedicto benedicatur,' may also be mentioned.

Grace, WILLIAM GILBERT, cricketer, was born 18th July 1848, at Downend near Bristol, fourth son of the village doctor; was a very distinguished cricketer by 1864, and soon was by far the foremost of cricketers, not merely playing in the great matches at home but making cricketing tours in Canada and the United States (1871), and Australia (1873). He studied medicine mainly at Bartholomew's Hospital (1875–78), and took L.R.C.P. at Edinburgh in 1879, whereupon he settled in practice at Bristol—finding time also for many a brilliant exhibition of his favourite game. He received a testimonial of £1400 in 1879, and in 1895, when he received one of over £5000, he had scored a century a hundred times. He published *Cricket* in 1891, and resigned the captaincy of the Gloucestershire eleven in 1899. His four brothers, all doctors, were also famous cricketers, especially George Frederick (1850–80). See his *Cricketing Reminiscences* (1899).

Gracedieu, a village 5 miles NE. of Ashby-de-la-Zouch, with ruins of a nunnery and the manor where Francis Beaumont (q.v.) was born.

Gracehill, a village with a Moravian settlement (1746) 2 miles SW. of Ballymena.

Graces (Lat. *Gratiæ*, Gr. *Charites*) divine personifications of grace, gentleness, and beauty, usually described as daughters of Zeus, who are given by Hesiod as three in number: Aglaia, Thalia, and Euphrosyne. The earliest conception seems to have been but one aspect of Aphrodite; the division into a plurality of beings came later. Originally the Lacedemonians had only two Charites, Cleta and Phaënna; the Athenians also had but Hegemone and Auxo. In the early ages the graces were represented in elegant drapery; at a later period slightly draped, or entirely nude, usually holding each other by the hand, or locked in each other's embrace.

Grackle. See GRAKLE.

Gradient, a term used chiefly in connection with railways to signify a departure of the line from a perfect level. See RAILWAY, ROAD.

Gradisca, a town of Austria, on the Isonzo, 25 miles NW. of Trieste. First fortified by the Venetians in 1478, Gradisca, with its territory, came into the hands of Austria in 1511, and during the next century and a half figured frequently in the wars between Austria and Venice. In 1647 it became a principality of the empire, but lapsed to the imperial crown again in 1717, and in 1754 was united to Görz (q.v.). Pop. 1464.

Gradual, an antiphon, introduced into the service of the Mass in the 5th or 6th century, sung after the epistle, and so called either from the altar-steps (*gradus*), where it was formerly sung, or because it was sung while the minister ascended the steps of the Ambo (q.v.) where the gospel was read. From Septuagesima to Holy Saturday the 'alleluia' with which the gradual is followed is replaced by a mournful chant called the *Tract*. The words of the gradual are nearly always taken from the Psalms; and they are invariably sung to 'plain chaunt' melodies, the compositions under this title of Haydn, Mozart, and others being graduals in name only. These melodies are contained in the *Gradual* (Old Eng. *Graile*), a volume of ritual music intended chiefly for the choir, and containing all the plain chaunt melodies appointed for the service of mass throughout the year.

Gradual Psalms, or SONGS OF DEGREES, a name given both by the Hebrews and in the Christian service-books to the fifteen psalms, 120–134 (119–133 in the Vulgate). The origin of this name is uncertain. The oldest explanation makes it an allusion to the fifteen steps between the courts of the temple, on each of which a later rabbinical tradition asserts that one of the psalms was sung; and others, again, have regarded these psalms either as containing a prophetic allusion to the return from captivity, or as having been sung in the 'going up' from Babylon. But the tradition has no support apart from the Talmud, and carries a suggestion of having been invented to meet the case; while the plural number of the title, 'goings up,' is against the second explanation. A third conjecture, which has more to recommend it, supposes that the psalms were sung by pilgrims when going up to Jerusalem for the great annual feasts. In the Roman Catholic Church they are recited on all Wednesdays in Lent, except the last.

Graduation. By the term graduation is meant those processes by which linear scales and circles, or circular arcs, are divided into any required number of parts. Such methods are constantly employed in the division of the scales of barometers, thermometers, cathetometers, reading arcs or circles of theodolites, sextants, telescopes, mural circles, spectroscopes, and in many other instruments where precision and accuracy of measurement is necessary. Since any mechanical process for executing such division must be preceded by some independent original graduation of the mechanical instrument itself, it is obvious that all methods of graduation must ultimately depend upon some original graduation. The subject may

therefore be considered first in reference to *original* graduation; and afterwards the reproduction, by hand or machine, of originally graduated lines or arcs may be dealt with.

The most elementary process in original graduation is the operation of dividing a line into a given number of equal parts. Let AB (fig. 1) be a line: it is required to divide it into, say, seven equal parts. From A draw AC, making any convenient angle with AB, and on AC lay off with compasses or a scale seven equal distances from A. Join BD, supposing D to be at the end of the seventh part on AC, and through the other points of division of AC draw lines parallel to BC. These will cut AB into seven equal parts. In practice, however, this method is not very accurate and is not often employed. In another method, that known as *continual bisection*, the length of half the line is laid off, by means of the beam-compass, from both ends; these lengths from the two ends should agree in one point as being the middle point of the line; if they do not, then the point midway between them is taken as being the middle point, and is found by means of a pair of fine compasses and a lens. Each half of the line is, by the same means, halved again, and so on until the required number of divisions is obtained. Similar division of a straight line may be obtained by laying off, by a pair of spring-dividers, one after another, from one end of the line, the smallest part required. Obviously, if there is any error in the first distance thus laid down, it will be multiplied in the last in proportion to the whole number of divisions. This method is known as *stepping*.

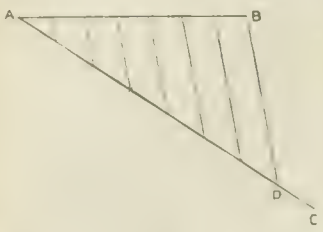

Fig. 1.

The original graduation of circles or of circular arcs is a matter of some difficulty, as it requires on the part of the operator such skill, patience, and care as is possessed by few. In this connection the names of Graham, Bird, Troughton, Ramsden, and Simms may be mentioned as those whose work has been of high value to the astronomer and physicist. The first method which may be described by which a circle can be divided is practically the same as that of bisection in the case of the straight line. Since the chord of an arc of 60° is equal to the radius of the circle (the chord and two radii to its extremities forming an equilateral triangle), if this length be laid off from any point on the circle an angle of 60° is thereby determined. The half of this angle may be obtained, and when added to 60° forms the quadrant or 90°. Continual bisection of 60° gives the smaller divisions of degrees and fractions of a degree. Troughton's method depends on an entirely different principle. A cylindrical roller is employed, whose dimensions are such that in rolling on its axis once round the outside edge of the circle it revolves sixteen times. The edge of the roller is itself divided into sixteen equal parts by repeated bisection. It is then held firmly by a frame against the edge of the circle, so that, on being moved always tangentially to the circle, it revolves on its axis round the edge of the circle. In doing so marks are made on the edge of the circle corresponding to the divisions on the roller; of these there will be 256, each interval being equal to 84⅜ minutes of arc. The further division of these intervals into degrees and minutes is effected by means of a subdividing sector, placed concentrically, and rolling with the roller. For the details of the manipulation of this sector reference may be made to Troughton's paper in the *Philosophical Transactions*, 1809.

The reproduction, or *copying* as it is termed, of graduated straight scales, circles, or circular arcs, by copying them from patterns originally graduated with great accuracy, may be done by hand or by mechanical contrivances. In copying a straight scale the 'work'—i.e. the piece of metal or other material whose division is required—is laid parallel to and flat with the pattern whose graduation is copied. A straight-edge is laid across both, so as to coincide with one of the divisions in the pattern, and the dividing-knife is drawn carefully along the edge, and across the work. In copying circles the work is screwed firmly down on and concentric with the pattern; the dividing-knife is then used in the same manner as in copying straight scales, being guided by an index steel bar, the edge of which is exactly coincident with a radius of the circle.

Copying is now more usually effected by instrumental means, the machines for this purpose being the linear and circular dividing-engines. In the linear dividing-engine the principal part is a carefully turned screw, which revolves in bearings in two supports. Connected with the screw is a crank handle and a disc whose plane is perpendicular to the axis of the screw, and whose flat edge is divided into a number, usually 400 or 500, of equal parts. As the handle is turned the screw rotates, but does not move in the direction of its length (it may, therefore, for distinction be referred to as the fixed screw). At the same time the disc also revolves, and each division on its edge passes an index line on a part of the support close to it; the number of complete turns and fractions of a turn of the screw may thus be easily counted. If, now, the fixed screw pass through a hollow travelling nut or screw, the latter will move backwards and forwards according as the fixed screw is rotated one way or the other. Thus, e.g., if the 'pitch' of the fixed screw be one millimetre, and the handle be turned ten times and a little more, corresponding to fifty-six divisions (of which let there be 500) on the graduated edge of the disc, the travelling-screw, and anything there may be in connection therewith, will advance through $10\frac{56}{500}$ mm.—i.e. 10·112 mm. The handle is so connected with a ratchet-wheel that the fixed screw can only be rotated in one direction, so that the travelling-screw can only travel in one direction, usually from left to right. Attached to the travelling-screw is the dividing-apparatus, which is a light frame supporting a vertically-placed steel needle, with a fine, hard point, and capable of a to-and-fro motion in a horizontal line at right angles to the fixed screw. This needle serves as a marker whereby divisions may be made on any object whose graduation is desired. For instance, to divide a given length into a certain number of equal parts, the travelling-screw is allowed to advance, by turning to the requisite amount, so that the point of the needle, starting from one end of the line, moves through a distance equal to one of the equal parts. A mark is then made with the needle; the travelling-screw is again advanced through precisely the same distance, and another mark is made; this process is continued until the whole length is divided. The length of mark made by the steel point may be adjusted, within certain limits, by increasing or decreasing, by screws, the range of the marking-point. In addition to this, however, it is desirable in some cases to make every tenth mark longer than the others, excepting the fifth, which may be intermediate. This is effected by a wheel whose circumference is cut up by rectangular notches, into

which one part of the frame holding the needle fits when at the end of its possible range of motion; every tenth notch being deeper than the others (except the fifth as above), the range of marking is longer in this case than the others. This wheel is turned by ratchet-work in the to-and-fro motion of the marking-point. The carriage attached to the travelling-screw may also support a small reading microscope: thus the linear dividing-engine may be used to test with great accuracy the distance between two points, each lying at the intersection of the cross-wires in the field of view; all that is necessary is to focus one of the points, count the number of whole and fractional turns of the screw required to bring the second point into focus, and thus the distance may be obtained.

For the purpose of dividing circles the circular dividing-engine is employed. This instrument was first constructed by Ramsden, afterwards improved by Troughton, and more recently by Simms. The essential features of a circular dividing-engine are a circular plate carefully divided by original graduation, and capable of rotation on its axis; a tangent-screw, working in a ratched edge of the circle, and thus capable of turning it through any required angle; a dividing-knife worked radially, so that, when the tangent-screw turns the circle through successive equal angles, radial lines may be drawn on any work laid on the divided circle. Fig. 2 represents one form of the instrument. A, A is the circle, usually 4 or 5 feet in diameter, divided at its edge, and ratched into teeth at its lower edge, C. The axis of the circle is in the column, E. TT′ is the tangent-screw; T′, a handle for turning it; T, a disc-shaped head, the divisions on the circumference of which allow of the number of whole and fractional turns of the screw being counted. The carriage, D, in which works the dividing-knife (not seen in the figure), may be adjusted to different heights by the screws on the pillars, P, which support the parallel beams on which the dividing-knife carriage moves; it may also be adjusted to circles of different radii by moving the carriage along these beams to the requisite amount from the centre. When in action the tangent-screw is pressed against the ratched edge of the circle by a handle, K, with an eccentric knob. This pressure may, of course, be relieved when the screw is not in use. The tangent-screw is sometimes turned by a treadle, or even by clock-work. Its pitch being accurately known, the angle through which the circle turns, due to one revolution of the tangent-screw, as noted by the divided head, T, is determined once for all for any machine. The work to be divided is fixed down on and concentric with the circle, A; a mark is made as origin with the dividing-knife, the tangent-screw is then made to turn the circle through one of the smallest divisions, and another mark is made; another equal turn of the screw is made and another mark cut on the circle, and so on until the division of the whole circle is completed. This is the method by which the large circles used in astronomical instruments are graduated, and such is the perfection to which these have been brought that the circular dividing-engine may be looked upon as being one of the most perfect of scientific measuring instruments.—For graduation in universities, see DEGREES, UNIVERSITY.

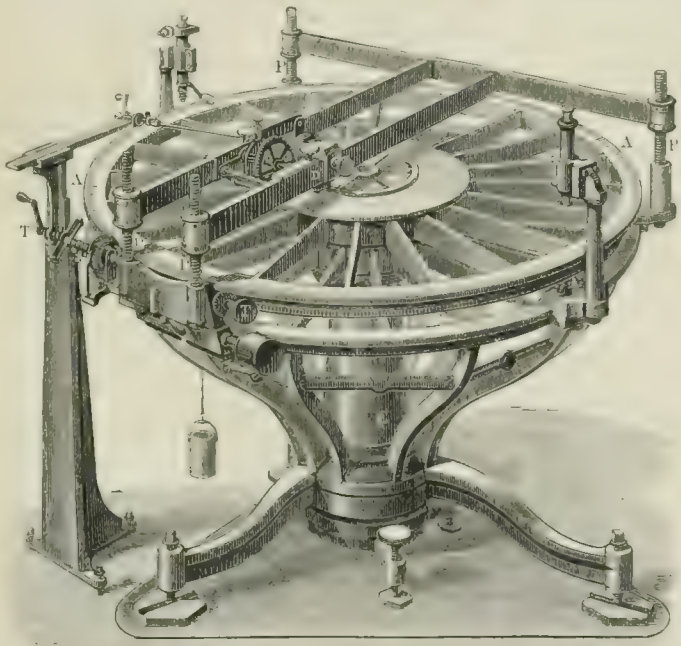

Fig. 2.—Dividing-engine.

Gradus ad Parnassum (Lat., 'a step to Parnassus'), a dictionary of prosody used in making Latin and Greek verse. The best known is the Latin one by John Carey, LL.D. (1756–1826), teacher of the classics and author of school-books, which was published in 1824.

Græcia. MAGNA. See MAGNA GRÆCIA.

Graetz, HEINRICH, Jewish theologian, was born in 1817 at Xions in Posen, and studied at Breslau, where in 1854 he became teacher in the Jewish seminary, and in 1870 also extraordinary professor in the University. He died 7th September 1891. He wrote commentaries on Ecclesiastes, Song of Solomon, Joel, the Psalms, and a work on Gnosticism and Judaism; but is remembered by his great *Geschichte der Juden* (11 vols. 1853–75; 4th ed. 1892; abridged in 3 vols. 1888–89 and translated in 5 by Bella Löwy in 1891–92).

Graf, ARTURO, Italian poet of German extraction, was born at Athens in 1848, spent his youth in Roumania, studied law at Naples, and in 1874 began to lecture on law in the University of Rome. Meanwhile he became eminent as a poet, has published several volumes of verse, and numerous works on literary history, myths, legends; and since 1882 is Professor of Italian literature at Turin.

Graf, HEINRICH, professor of theology at Leipzig, studied under Reuss at Strasburg, and died 16th July 1869. His name is identified with the theory of the Pentateuch taught by Reuss in 1833 that the 'Priestly Document' of the Pentateuch was written after the exile. See PENTATEUCH.

Gräfenberg, a village in the north-west corner of Austrian Silesia, 50 miles N. of Olmütz. It is celebrated as the spot where the water-cure (see HYDROPATHY) was introduced in 1826 by Vincenz Priessnitz (1799–1851). It still is visited yearly by some 1500 persons.

Graffiti (Ital. *graffito*, 'a scratching'), or WALL-SCRIBBLINGS, the name given to certain classes of mural inscriptions and drawings found at Pompeii, Rome, and other ancient cities in Italy. They are generally scratched, with a stylus or similar sharp instrument, or scrawled, with red chalk or charcoal, on walls, door posts, and portico pillars, and seem to be the work of idle schoolboys, loungers, trifflers, and the like 'do-nothing' folk; but some were executed with more serious intention. Accordingly we find that the subjects that oftenest occur are doggerel verses, quotations from the poets, amatory

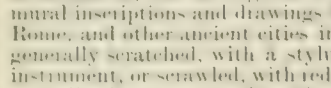

Fig. 1.—Specimen of Graffiti—*Auge amat Arabienum* ('Auge is in love with Arabienus').

effusions, names with opprobrious epithets attached, coarse and often obscene words and figures, rude caricatures, especially of gladiators, of which fig. 2 is a specimen, and other instances of the thousand and odd ways in which the impulses of the restless idler prompt him to express his fancies. Amongst the more serious examples there are electioneering admonitions, playbills, and similar public announcements, philosophic apophthegms, notices of household events, time-tables of domestic work, and exclamations and sentences of even tragic import. These scribblings and rude drawings derive importance from the fact that, like *Punch* and similar comic journals, they serve as an admirable index to the current life of the people, especially in Pompeii, where the greatest number of them have been discovered. Without them we should have a far less adequate idea of the street-life of the ancient Roman people. They also throw much light upon the phraseology and idiom of the vernacular spoken towards the end of the 1st century A.D. in the cities of southern Italy. Three languages, or rather three alphabets, were used Latin, Greek, and Oscan. Of these Latin was much the most commonly employed. In Rome *graffiti* have been found on some of the great buildings of the ancient city, as the Palace of the Cæsars, Nero's Golden House, and tombs on the Via Latina, as well as in the Catacombs. These last consist for the most part of lists of mere names, pious prayers and wishes, and invocations to the martyrs. The first collection of *graffiti* from Pompeii was published by Bishop Christopher Wordsworth in 1837, and is reprinted in his *Miscellanies* (1879). All that have been discovered and published up to the present time are to be found in vol. iv. of *Corp. Inscr. Lat.* (1871, edited by Zangemeister under the title *Inscriptiones Parietariæ Pompeianæ, Herculanenses, et Stabianæ*) and the supplementary volume. The inscriptions in the Oscan characters, of which there are two varieties, as there likewise are of both the Greek and the Latin, are not contained in the collections just quoted; but they will be found in Fiorelli's *Inscr. Oscarum Appographa* (1854). Compare also Garrucci's *Graffiti de Pompei* (Paris, 1856), and *Edinburgh Review*, vol. cx.

Fig. 2.—Gladiator.

Gräfrath, a town of Rhenish Prussia, 12 miles E. by S. of Düsseldorf, with cotton and iron manufactures. Pop. 6699.

Grafting, a mode of propagation applicable to all kinds of trees and shrubs, and even herbaceous plants whose tissues are firm. The operation consists in the inserting of a branch or bud (*scion*) of one tree into some part of another tree (*stock*), so as to bring about a union of the two. The practice of grafting is doubtless one of great antiquity, and its origin may in all probability be traced to a natural process which is of frequent occurrence. It has been observed that, when two branches of a tree or branches and even the stems of kindred trees growing closely together overlap and touch each other, the bark becomes wounded or abraded, and the returning juices exuding from the ruptured vessels in the *Alburnum* (q.v.) produce granulations by which a perfect incorporation of structure is effected, and the parts become one. The object of grafting is, first, to perpetuate and increase the stock of varieties and sub-varieties of fruit-trees, the innate qualities of which cannot be transmitted with certainty to their progeny by seeds, and which would be more slowly and less surely multiplied by any other artificial mode of propagation; secondly, to increase and accelerate the fruitfulness of fruit trees—for, the elaborated sap being impeded in its descent at the junction of the scion with the stock, the process of maturation is thereby promoted, and fertility more largely and quickly induced. Old and unfruitful trees, whose stems and roots are vigorous and healthy, may be rendered fruitful in the course of two or three years by having their tops cut back and re-grafted with scions from a fruitful and healthy tree. Grafting is also employed for the purpose of dwarfing fruit-trees, while at the same time abnormally increasing their fruitfulness. This is attained partly by the selection of a stock which exerts a restrictive influence on the scion, and by double grafting—i.e. grafting twice or oftener at will. Very young trees are thus rendered prodigiously fruitful, and are in demand for the purpose of pot culture and planting in orchard-houses. Trees damaged by wind or otherwise have their injuries repaired by grafting, and those that are unequally balanced may be brought to perfect symmetry by the judicious insertion of scions in the ill-furnished parts.

In grafting it is particularly to be attended to that the *alburnum* of the scion is brought into contact with that of the stock. The hard wood of the one never unites with that of the other, remaining separate and marking the place of the operation even in the oldest trees. For scions or grafts, pieces of about six to eight inches long are generally taken from the shoots of the previous summer, with several buds; but portions of shoots of two years old are sometimes successfully employed. The time for grafting is in spring, as soon as the sap begins to appear. The scion should, if possible, be taken from a healthy and fruitful tree, but scions from the extremities of lateral branches are more likely to become speedily fruitful than those from the uppermost branches, where growth is most vigorous. The scion should be kept for a few days before grafting, so that the stock may rather exceed it, not only in vigour, but in the progress of its spring growth; and for this purpose it may be placed in the ground, in a rather dry soil, sheltered from the direct rays of the sun. Scions may be kept for some time, and easily carried to a distance,

by sticking their lower end into a potato or moist moss or clay. The end should always be freshly cut off when the scion is to be used. There are various modes of grafting. *Cleft-grafting* (fig. 1) is very commonly practised when the stock is very considerably thicker than the scion. The stock, being cut over, is cleft down, and the graft, cut into the shape of a wedge at its lower end by a sharp thin knife, is inserted into the cleft. This mode of grafting is particularly applicable to branches of large trees, when the introduction of a new variety of fruit or increased fruitfulness is sought.—*Crown-grafting* is used for still thicker stocks, which are cut across, and then cleft down by two clefts crossing one another at right angles, two scions being inserted close to the bark in each cleft; or no cleft at all is made, and any desired number of scions obliquely cut away on one side are simply inserted between the bark and wood of the stock, the operation in this case being deferred till the bark readily parts from the wood. In this kind of grafting a longitudinal slit in the bark of the stock, opposite to each graft, is advantageous. — *Tongue-grafting* (fig. 2) is the mode most commonly practised for young trees in nurseries. For this it is necessary that the stock and the scion should be of not very different thickness. A slit or a very narrow angular incision is made in the centre of the stock downwards, and a similar one in the scion upwards, both having been first cut obliquely at corresponding angles; and, the tongue thus made in the scion being inserted into the incision in the stock, they are fastened very closely and thoroughly together. In *saddle-grafting* the end of the stock is cut into the form of a wedge, and the scion is affixed to it, the base of the scion having been cut or slit up for the purpose.—*Shoulder-grafting*, used chiefly for ornamental trees, is performed by cutting obliquely, and then cutting across a small part at top of the stock, so as to form a shoulder, the scion being cut to fit it.—*Peg-grafting*, not now much in use, is accomplished by making the end of the scion into a peg, and boring the top of the stock to receive it.

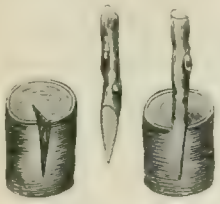

Fig. 1.—Cleft-grafting.

Fig. 2.
a, tongue-grafting; *b*, do. with ligature applied; *c*, do. with clay applied.

Whichever of these modes of grafting is adopted the graft must be fastened in its place by tying, for which purpose a strand of bast-matting is commonly used. The access of air is further prevented by means of clay, which has been worked up with a little chopped hay, horse or cow dung, and water, and which is applied to the place of junction so as to form a ball, tapering both upwards and downwards. In France a composition of 28 parts black pitch, 28 Burgundy pitch, 16 yellow wax, 14 tallow, and 14 sifted ashes is generally used instead of clay. The progress of the buds shows the union of the graft and stock, but it is not generally safe to remove the clay in less than three months; and the ligatures, although then loosened, are allowed to remain for some time longer. From some kinds of fruit-trees fruit is often obtained in the second year after grafting.

Budding (q.v.) is in principle the same as grafting; and *flute-grafting* is a kind of budding in which a ring of bark with one or more buds is used instead of a single bud, and, a stock of similar thickness having been cut over, a corresponding ring of bark is removed, and the foreign one substituted. This is commonly performed in spring, when the bark parts readily, and is one of the surest modes of grafting.—*Inarching* or *grafting by approach*, in which the scion is not cut off from its parent stem until it is united to the new stock, is practised chiefly in the case of some valuable shrubs kept in pots, in which success by the ordinary methods is very doubtful.

An effect is produced by the stock on the scion which it nourishes analogous to that of a change of soil; much of the vigour of a strong healthy stock is also communicated to a scion taken even from an aged tree. There is, moreover, in some degree, an influence of the elaborated sap descending from the scion on the stock which supports it. An important part of the practical skill of the gardener or nurseryman consists in the selection of the proper kinds of stocks for different species and varieties of fruit-trees. The stock and scion, however, must not be of species extremely dissimilar. No credit is due to the statements of ancient authors about vines grafted on fig-trees, apples on planes, &c., the semblance of which can only have been brought about by some delusive artifice; for all attempts at grafting fail except among plants of the same genus, or at least of the same natural family.

Herbaceous plants with firm stems, as dahlias, are sometimes grafted. Some kinds of plants, of small size, in pots, are placed in moist hothouses or hotbeds, under bell-glasses, whilst the junction of the scion and stock is going on, which in these circumstances takes place very surely and very expeditiously. But an accumulation of too much moisture under the bell-glass must be guarded against.

Grafton, a rising town of New South Wales, 350 miles NE. of Sydney, situated on both sides of the Clarence River, and 45 miles from the sea. The river is navigable. The agricultural district yields sugar and tobacco; and gold, silver, coal, and copper are found. Pop. 4770.—Grafton is also a town of 5000 inhabitants, 9 miles SE. of Worcester in Massachusetts; and of a railway centre (pop. 3100) in West Virginia, 99 miles SE. of Wheeling.

Grafton, Augustus Henry Fitzroy, Duke of, statesman, a descendant of Charles II., was born 1st October 1735, and in 1757 succeeded his grandfather, the second duke (see Charles II.). He first came to the front in political life in 1763 in the opposition to Bute, and in July 1765 he took office as Secretary of State under Rockingham, but resigned in the following May. Two months later Pitt became premier and Earl of Chatham, making Grafton First Lord of the Treasury; but in consequence of Chatham's continued illness Grafton was compelled to take upon his own shoulders the responsible duties of head of the government from September 1767. He resigned in 1770, accepted the office of Lord Privy Seal under Lord North in 1771, and filled it until November 1775. When the new Rockingham ministry was formed in March 1782 Grafton took his old post as Lord Privy Seal, but resigned office thirteen months later. He died at Euston Hall, Suffolk, 14th March 1811. Indolent, vacillating, somewhat obstinate in his political life, and openly immoral in his private life, Grafton was the target at which Junius (q.v.) shot some of his sharpest invectives.

Gragnano, a town of Italy, 20 miles by rail SE. of Naples, with manufactures of wine and macaroni. Pop. 8611.

Graham, the name of an illustrious Scottish family of Anglo-Norman origin, who settled in Scotland during the 12th century. A Sir William de Graeme received from David I. the lands of Abercorn and Dalkeith, and extensive grants of estates were made to his descendants by William the Lion, Alexander II. and III., and by King Robert Bruce. One of their chiefs, Sir John de Graham of Dundaff, was the bosom friend of the patriot Wallace, and was killed at the battle of Falkirk, July 22, 1298. From the war of independence downwards the Grahams have taken a prominent part in the public, and especially in the warlike, affairs of the country. Patrick Graham of Kincardine was made a peer in 1451 under the title of Lord Graham. His grandson was created Earl of Montrose by James IV. (1504–5), and fell with his sovereign at the battle of Flodden. The third earl twice held the office of High Treasurer of Scotland, and was appointed Lord Chancellor in 1599. On resigning that office he was appointed Viceroy of Scotland for life. His grandson, the fifth earl and first Marquis of Montrose, is the glory of the House of Graham (see MONTROSE). His eldest surviving son, who was born in 1631 and died in 1699, was termed the 'Good Marquis.' He was peculiarly amiable in his disposition, and delighted in the quiet and peace of private life. The fourth marquis was appointed High Admiral of Scotland in 1705 and President of the Council in 1706. He was a firm supporter of the union between England and Scotland, and was created Duke of Montrose in 1707. He held the office of Keeper of the Privy Seal under Queen Anne (1709–13), was appointed Secretary of State for Scotland by George I. in 1717, and a second time Keeper of the Great Seal in Scotland. He was Chancellor of the university of Glasgow, and died in 1742. His grandson, the third duke, held in succession, under the ministry of William Pitt, the offices of one of the Lords of the Treasury, Paymaster of the Forces, one of the Commissioners of the Indian Board, Master of the Horse, Lord Justice-general of Scotland, President of the Board of Trade, and Joint Paymaster of the Forces. He was also, like his father, Chancellor of the university of Glasgow, and Lord-lieutenant of the counties of Stirling and Dumbarton, in which he had great influence. 'Few individuals,' says Sir Nathaniel Wraxall, 'however distinguished by birth, talents, parliamentary interest, or public services, have attained to more splendid employments, or have arrived at greater honours.' He died in 1836. The fourth duke was Lord Steward of the Household, Chancellor of the Duchy of Lancaster, and Postmaster-general. He died in 1874. The family honours and estates were then inherited by his third and only surviving son, the fifth duke. It is noteworthy that the title of the family is not taken from the town of Montrose, but from their hereditary estate of 'Auld Montrose,' which David Graham received from Robert Bruce in exchange for the lands of Cardross in Dumbartonshire.—The Grahams of Fintry, Duntrune, Inchbrakie, Esk, Menteith, Netherby, and Norton Conyers are minor branches of the family. See Dr James Taylor's *Great Historic Families of Scotland* (1887).

Graham, DOUGAL, the literary bellman of Glasgow, was born in the village of Raploch, near Stirling, about 1724. He was a hunchback, and from an early age laboured irregularly as a farm-servant. He followed Prince Charlie's army on its southern march to Derby, apparently as a kind of sutler, and made his way home soon after the disaster at Culloden. Five months later he had his metrical narrative ready, which, grotesque and pitiful doggerel as it is, has no mean value as a record of the fresh observations of an honest and not unintelligent eye-witness. Soon after this he took up his abode in Glasgow, where his ready wit soon made him something of a public character, but he still plied his calling as a prosperous chapman or pedlar. Here also he made himself the poetical chronicler of passing events, and wrote many of the chap-books which he sold, and which quickly became extraordinarily popular. He was appointed 'skellat' bellman (for ordinary announcements) of the city, not earlier than 1770; but there is no mention of his name in the town-council records. He died 20th July 1779. Many of his rambling ballads and prose chap-books were anonymous, and are now impossible to trace; of the former the best known are *John Highlandman's Remarks on Glasgow* and *Turnimspike*. His numerous prose chap-books are both humorous and good-humoured, but never touch the region of the literary, and are moreover disfigured by a constant coarseness and by occasional grossness of obscenity which admit of no extenuation.

The most popular were *The Whole Proceedings of Jockey and Maggy, Paddy from Cork, Lothian Tom, The History of John Cheap the Chapman, the Comical and Witty Jokes of John Falkirk the Merry Piper, Leper the Tailor, John Falkirk's Cariches, Comical History of Simple John and his Twelve Misfortunes,* and *George Buchanan*. Both Scott and Motherwell meant to have edited some of Dougal Graham's work. This was finally done in a complete edition in two handsome volumes by George MacGregor (Glasgow, 1883).

Graham, SIR JAMES ROBERT GEORGE, English statesman, was born at Netherby, in Cumberland, June 1, 1792, and educated at Westminster and Queen's College, Cambridge. As private secretary to the British minister in Sicily in 1813, he had a hand in the negotiations with Murat at Naples. After his return for Carlisle as a Whig in 1826 he became a warm supporter of Catholic emancipation and a zealous advocate of the Reform Bill. Earl Grey thereupon offered him, in 1830, the post of First Lord of the Admiralty, with a seat in the cabinet. But in 1834 he seceded from the government, disagreeing with his colleagues on the appropriation clause of the Irish Church Temporalities Act; and, going over to the Conservatives, became in 1841 Home Secretary under Sir Robert Peel. In 1844 he issued a warrant for opening the letters of Mazzini, and caused the information thus obtained to be communicated to the Austrian minister, an act by which the ministry, and Graham in particular, incurred great obloquy. He also encountered great displeasure north of the Tweed by his high-handed method of dealing with the Scottish Church during the troubles which ended in the Disruption and the formation of the Free Church. He gave Peel warm support in carrying the Corn Law Repeal Bill, and resigned office (1846) with his chief as soon as that measure was carried. On the death of Peel in 1850 he became leader of the Peelite party in the Lower House, and in December 1852 took office in the Coalition Ministry as First Lord of the Admiralty. He retired from official life in February 1855, and died at Netherby, October 26, 1861. See Life by Torrens (2 vols. 1863) and by Lonsdale (1868).

Graham, JOHN, VISCOUNT DUNDEE, was the elder son of Sir William Graham of Claverhouse, in Forfarshire. His birth is placed with more likelihood in 1649 than in 1643, for he did not matriculate at St Andrews till February 1665. After three years there, then four perhaps soldiering under Turenne, in 1672 he entered the Dutch service as cornet in the Prince of Orange's horse-guards. In 1674 at the battle of Seneff he saved (according to the *Grameid*) William's life; in 1677

he returned to Scotland, and next year received a commission as lieutenant in a troop of horse commanded by his cousin, the third Marquis of Montrose. At this time the government of Charles II. was engaged in its insane attempt to force Episcopacy upon the people of Scotland. A system of fines and military coercion was carried on against all nonconformists; conventicles and field-preachings were prohibited; penalties were inflicted on all who even harboured the recusants; and the nation lay at the mercy of informers. Maddened by oppression, and fired by a fierce zeal for the Covenant, the western peasantry flew to arms; but their efforts were irregular and detached, and each successive failure only aggravated their sufferings. Many were executed; the gaols were crowded with prisoners; and those who fled were outlawed, and their property confiscated. In this miserable service Claverhouse, now sheriff-depute of Dumfriesshire, was employed. At Drumclog, on Sunday, 1st June 1679, he encountered an armed body of Covenanters, but was defeated, some forty of his troopers being slain, and himself forced to flee from the field. Three weeks later, at Bothwell Brig, he served as a simple captain of cavalry. These are the only affairs that can even by courtesy be called battles in which Claverhouse was engaged in Scotland previous to James II.'s abdication. They displayed no generalship. In detecting and hunting down the Covenanters he evinced the utmost activity; still, he had nothing whatever to do with the Wigtown martyrdoms, and if he caused shoot John Brown, the 'Christian Carrier,' it was after finding of arms and refusal to take the oath of abjuration. He rose to the rank of colonel, and in 1682 became sheriff of Wigtownshire, in 1683 was sworn a privy-councillor, in 1684 got a gift of the Forfarshire estate of Dudhope, and was made constable of Dundee. That same year he married Lady Jean Cochrane, the daughter of a Whig house, who bore him one short-lived son, and who afterwards wedded the Viscount of Kilsyth. In November 1688, on his march up to London to stem the Revolution, Claverhouse was raised to the peerage as Viscount Dundee; four months later he rode with fifty troopers out of Edinburgh, and, being joined by the Jacobite clans and three hundred Irish, raised the standard for King James against William and Mary. After various rapid movements in the north, he seized Blair Castle, the key of the Highlands; and General Mackay, commanding the government forces, marched against him from Edinburgh. On the evening of 27th July 1689 the two armies met at the head of the Pass of Killiecrankie. Mackay's force was between 3000 and 4000; Dundee's only 2000. Two minutes decided the contest; before the wild rush of the clansmen the redcoats wavered, broke, and ran like sheep. Their loss was 2000, the victors' 900 only; but one of the 900 was Ian Dhu nan Cath (or 'Black John of the Battles'), as the Highlanders called Dundee. A musket-ball struck him as he was waving on his men, and he sank from his saddle into the arms of a soldier named Johnstone. 'How goes the day?' murmured Dundee. 'Well for King James,' said Johnstone, 'but I am sorry for your lordship.' 'If it is well for him,' was the dying man's answer, 'it matters the less for me.' Wrapped in two plaids, his body was borne to Blair Castle; and in the church of Old Blair they buried him, where in 1889 the Duke of Athole placed a tablet to his memory.

'Bloody Claverse,' 'Bonnie Dundee'—the two names illustrate the opposite feelings borne towards one whom the malice of foes and the favour of friends have invested with a factitious interest. He was neither the devil incarnate that legend and Lord Macaulay have painted him, nor the 17th-century Havelock of Aytoun, Napier, and Paget. True, Wodrow himself admits that 'the Hell-wicked-witted, bloodthirsty Graham of Claverhouse hated to spend his time with wine and women;' Lochiel's biographer records how he never was heard to swear, and how, 'besides family worship, performed regularly evening and morning in his house, he retired to his closet at certain hours, and employed himself in that duty.' But, then, we have Claverhouse's own admission (1679): 'In any service I have been in I never inquired farther in the laws than the orders of my superior officers'—an admission that accuses whilst excusing, and that is applicable to his whole career. Bonnie at least he was in outward form, with the 'long dark curled locks,' and the 'melancholy haughty countenance,' which we know by his portraits and by Scott's matchless description.

The letter purporting to be written to James II. by Dundee after he had got his death wound, and first published in Macpherson's *Original Papers* (1775), is almost certainly a forgery, though not Macpherson's. The *Grameid* is a long but unfinished Latin epic by James Philip of Almerieclose (*c.* 1656–1713), one of Dundee's followers. Written in 1691, it was first edited by the Rev. A. D. Murdoch for the Scottish History Society (1888). Mark Napier's *Memorials and Letters of Dundee* (3 vols. 1859–62) is perhaps the worst life in the language, still well worth sifting. See also Aytoun's *Lays of the Scottish Cavaliers* (1849); Paget's *Paradoxes and Puzzles* (1874); *Claverhouse*, by Mowbray Morris ('English Worthies' series, 1887); and *Clavers, the Despot's Champion*, by 'a Southern' (1889).

Graham, THOMAS, a Scottish chemist, was born in Glasgow, 21st December 1805. Having studied at Glasgow and Edinburgh, he became in 1830 professor of Chemistry in his native city, and in 1837 he accepted the corresponding chair at University College, London. In 1855 he was appointed Master of the Mint, and resigned his professorship. He died in London, 16th September 1869. His name is most closely associated with the subject of the molecular diffusion of gases, his researches in connection with which led him to formulate the law 'that the diffusion rate of gases is inversely as the square root of their density.' Amongst his important memoirs on chemistry we may mention the following: 'Absorption of Gases by Liquids;' 'Absorption of Vapours by Liquids;' 'Law of Diffusion of Gases;' 'Researches on the Arseniates, Phosphates, and Modifications of Phosphoric Acid;' 'Motion of Gases, their Effusion and Transpiration;' 'Diffusion of Liquids;' 'Liquid Diffusion applied to Analysis;' 'Liquid Transpiration in Relation to Chemical Composition;' and 'Molecular Mobility of Gases.' These were contributed to various scientific journals, and were collected in 1876. His excellent *Elements of Chemistry* appeared in 1837. See *Life and Works of Graham*, by Dr R. Angus Smith (Glasgow, 1884).

Graham, THOMAS. See LYNEDOCH (LORD).

Grahame, JAMES, author of *The Sabbath*, was born at Glasgow, April 22, 1765. The son of a prosperous lawyer, he went in 1784 to Edinburgh to study law, and, after qualifying as a writer to the Signet, was admitted as an advocate in 1795. Finding law uncongenial, at forty-four he took orders, and was successively curate of Shipton in Gloucestershire and of Sedgefield in the county of Durham. Ill-health compelled him to return to Scotland, where soon after he died, September 14, 1811. Grahame's poetical works include *Mary, Queen of Scots*, a dramatic poem (1801); *The Sabbath* (1804); *British Georgics* (1804); *The Birds of Scotland* (1806); and *Poems on the Abolition of the Slave-trade* (1810). His fame rests securely on his

blank verse poem, *The Sabbath*. It falls far short of Cowper's vigour, variety, and real genius, but in its tender devotional feeling and occasional felicity in describing quiet Scottish scenery it is not unworthy of that master, whom he resembled further in the retiring amiability of his character.

Graham's Land, an island of the Antarctic Ocean, discovered by Biscoe in 1832, lies between 65° and 67° S. lat. In front, towards the north, are a number of islets, called Biscoe's Chain.

Grahamstown, the capital of the eastern province of Cape Colony, stands near the centre of the maritime division of Albany, 1728 feet above sea-level. By rail it is 106 miles NE. of Port Elizabeth, and 43 NW. of Port Alfred. It is the seat of two bishops—Anglican and Roman Catholic; and in its Anglican cathedral is a monument to Colonel Graham, after whom the city is named. Leather is manufactured, and among the institutions of the place are its museum, St Andrew's College, a public library, a general hospital, and large barracks. Pop. (1875) 6903; (1891) 16,498, of whom about 7000 are whites.

Grahamstown, New Zealand. See THAMES.

Graian Alps. See ALPS.

Grail, LEGEND OF THE HOLY (etymology uncertain). The spelling varies considerably in the oldest texts from *graal* to *greaus*. A vessel of some kind is obviously intended, and derivation has been suggested from the Low Lat. *gradalis* or *gradalus* ('a shallow vessel'), which appears also in the forms *grasale*, *grassale*, *grazala*, and Old Fr. *grasals* or *grazals*. See Ducange-Favre, *Gloss. Med. et Inf. Lat.*, under 'Grasala.' This etymology is supported by the testimony of Helinandus (*c.* 1204), 'gradalis dicitur gallice scutella lata et aliquantulum profunda, in qua dapes solent apponi, et dicitur nomine graal.' Diez, *Etymol. Wörterbuch*, 601, suggests a lost *cratalis* from *cratus*, the Low Latin form of *crater*, as the original of the above-cited forms. Other etymologies have been suggested, but all are worthless.

Chronological Arrangement of the Grail Romances.—(*a*) Chrestien's portion of the Conte du Graal, *circa* 1190; (*b*) Gautier de Doulens' continuation of same, *circa* 1195 in one form, with expansions *circa* 1200; (*c*) Robert de Borron's poem, 1200–10; (*d*) Queste del Saint Graal, about the same date; (*e*) Grand St Graal, only known in a redaction of *circa* 1230–50, but extant in a less extended form prior to 1204; (*f*) Wolfram von Eschenbach's Parzival, *circa* 1210; (*g*, *h*) continuation of Conte du Graal by Manessier and Gerbert, *circa* 1220–30; (*i*) the prose Perceval le Gallois, *circa* 1225; (*k*) prose continuation of Robert de Borron's poem known as the Didot Perceval, *circa* 1230–50; (*l*) Heinrich von dem Türlin's Diu Krone, prior to 1250. Personages and part of the subject-matter of the Grail romances also appear in (*m*) the Mabinogi of Peredur ab Evraw and (*n*) the alliterative metrical romance Sir Perceval. Both these last are in 14th–15th century MSS., but are certainly older, though posterior in their present form to Chrestien, whom both have used.

Subject-matter of the Romances. The legend consists of two portions: a Quest relating (1) how Perceval comes to the castle of the Fisher King, sees the Grail, fails to ask concerning it, is reproved, has to wander many years, comes a second and third time to Grail Castle, makes whole a broken sword or slays the enemy of the Fisher King, is hailed by the latter as his nephew, and succeeds him in his kingship (*a*, *b*, *f*, *g*, *h*), or releases him at once from supernaturally prolonged life (*k*) or from the enchantment of death in life (*l*) (the same incidents as in *a*, *f*, *g*, *h* reappear in part in *m*, but the Grail is replaced by a head in a dish); (2) how Galahad, Perceval, and Bors alone of Arthur's knights succeed in beholding the Grail, follow it to the east, where Galahad and Perceval die, but Bors returns to Arthur's court (*d*, *e*)—and an Early History relating how the Grail was given by Christ to Joseph of Arimathea (*c*, *d*, *e*, *g*, *h*, *k*), and how it came to England either in the charge of Brons, Joseph's brother-in-law (*c*, *k*), or of Josephe, Joseph's son (*d*, *e*). In all these versions the Grail is a cup or vessel, and in the Early History forms it is the cup used first by Christ at the Last Supper, secondly by Joseph to collect the blood which flowed from Christ's wounds as he hung upon, or after his body was descended from, the cross. In (*f*) Wolfram an entirely different account is found: the Grail is a precious stone, fallen from heaven, and given in charge to Titurel and his dynasty the Grail kings.

Nature and Properties of the Grail.—In the Quest romances, the oldest portion of the cycle, and notably in the Conte du Graal, the Grail is simply a miraculous food-producing vessel. With a broken sword which only the destined hero can make whole, and a lance which drops blood, it is simply one of three talismans, and its importance in the conduct of the story is not greater than theirs. The Christianisation of the legend brought about a profound change in the conception of the Grail. This change is only fully manifest in Robert de Borron, where the properties of the Grail are exclusively spiritual: it separates the pure from the impure, and gives to the former as full and sweet solace as their heart could long for. In the other Early History forms, and in those later Quest versions which have been affected by the Early History, the Grail retains its material side by side with its spiritual properties, even where, as in the case of *d*, *e*, and *h*, these versions are written in a mystical and theological spirit. From (*d*) Queste we learn that the Grail strikes with dumbness those to whom it appears. In Wolfram (*f*) the spirit is likewise mystical and theological, but of course the sacramental nature of the Grail, so prominent in those romances which identify it with the Last Supper cup, is wanting, hence the symbolism is on different lines. Here too, however, the material properties of the Grail are as strongly insisted upon as the spiritual ones.

Hypothetical Development of the Legend.—The Grail is originally a portion of the gear of old Celtic divinities, more especially of the god of the underworld, whose name among the Cymry was Bran. Numerous Celtic sagas, as well as existing Celtic folk-tales, tell of a hero who journeys to the land of shades and brings back talismans, prominent amongst them the inexhaustible vessel of plenty and rejuvenation. At an early period this tale got mixed up with a Peredur saga, in which the hero, to avenge a kinsman, had to seek for a magic lance and sword. The result of the fusion may be traced in the forms which underlie the Mabinogi of Peredur, the Conte du Graal, and the metrical Sir Perceval. Peredur thus came in contact with Bran, lord of the under-world, who was identified with Bran the Blessed, whom later Welsh tradition made the hero of a conversion of Britain story. This Bran is the Brons of the Joseph of Arimathea legend, and by this means the old Celtic heathen vessel of increase and youth came into connection with the follower of Christ, who was at an early date a favourite legendary figure on British soil, the Evangelium Nicodemi which relates his legend having been widely known there at a time when continental literature is altogether silent regarding it. The Christianisation of the Celtic saga had probably begun before Chrestien, though only to a very slight extent. It was fully carried out by men who wrote after, and in

opposition to him, and who wished to make the story a vehicle for moral and religious teaching. Robert de Borron alone worked out the conception in a fairly consistent way; in the other theological romance-writers—e.g. the authors of the Queste, of the Grand St Graal, and Gerbert—the Graal is at least as much heathen as Christian. In these romances the tendency is rather moral than dogmatic: they are in the main glorifications of asceticism, and in especial of physical chastity. This latter idea, almost foreign to the earlier works of the cycle, is most fully worked out in the Queste, a new hero, Galahad, being especially created to typify the virtue of virginity. The Queste was one of the romances used by Malory in his Morte Darthur; hence the Galahad story has had a great and abiding influence upon English literature through Tennyson and others. Wolfram von Eschenbach, like Robert de Borron and the author of the Queste, received the story from Chrestien, and, like them, was dissatisfied with the latter's treatment of it. He, however, has worked out a religious and ethical ideal of a far nobler and truer kind than that found in the Queste. His conception is based, not upon chastity, but upon charity, and the Grail becomes with him a symbol, not of ascetic longing and its unearthly reward, but of human striving and human love in their noblest manifestation.

Evidence in support of the foregoing contentions, together with full summaries of the romances themselves, and bibliography and analysis of the investigations of previous students, will be found in the writer's *Studies on the Legend of the Holy Grail, with especial Reference to the Hypothesis of its Celtic Origin* (1888). Compare also M. Gaston Paris's *Histoire Littéraire de la France*, vol. XXX. (1888); and for alleged Buddhist influence upon the Grail legend, the writer's article in the *Archæological Review*, June 1889. See also ROMANCES, MAP (WALTER), TENNYSON.

Graile. See GRADUAL.

Grain. For grain imports and exports, see FOOD, Vol. IV. p. 720; also the articles WHEAT, &c.

Grain, as a unit of weight, is supposed to be the average weight of a seed or well-ripened ear of wheat; of such grains 7000 are held to be a pound avoirdupois. The grain is also the 20th part of a scruple in apothecaries' weight, and the 24th part of a pennyweight troy. See also GRAMME.

Grain Coast. See GUINEA.

Graining, a kind of dace found in the Mersey and some few English rivers, and in Swiss lakes, distinguished by Pennant and Yarrell as a separate species (*Leuciscus lancastriensis*), but regarded by Günther as only a local variety of the dace (*L. vulgaris*). See DACE.

Grains of Paradise, or MALEGUETTA PEPPER, an aromatic and extremely hot and pungent seed imported from Guinea. It is the produce of *Amomum Grana Paradisi*, a plant of the order Zingiberaceæ. By the natives these seeds are used as a spice or condiment; in Europe chiefly in veterinary practice, and fraudulently to increase the pungency of fermented and spirituous liquors. By 56 Geo. III. chap. 58, brewers and dealers in beer in England were prohibited, under a heavy penalty, from even having grains of paradise in their possession. This drug is much used to give apparent strength to bad gin. The name Maleguetta Pepper, or Guinea Pepper (q.v.), is also given to other pungent seeds from the west of Africa.

Grakle, the common name of many birds of the Starling family (Sturnidæ), all tropical or subtropical. They have very much the habits of starlings, which some of them even excel in their imitative powers, and particularly in the imitation of human speech. This is remarkably the case with the Mina Birds or Hills Mynas (*Gracula javana*), common in India, which are easily tamed and taught. Many grakles feed on seeds and fruits, while others are useful as destroyers of insects. See STARLING.—In the United States the name Grakle or Grackle is applied to several species of the genera Scolecophagus and Quiscalus, omnivorous birds, also called 'blackbirds' and 'boat-tails.'

Grallæ, or GRALLATORES (Lat., 'stilt-walkers'), an old order of wading and running birds, including rails (Rallidæ), snipes and curlews (Scolopacidæ), plovers (Charadriidæ), bustards (Otididæ), cranes (Gruidæ), herons and bitterns (Ardeidæ), storks (Ciconiidæ), and numerous other families. These are grouped by modern ornithologists in a number of smaller orders, while the old order Grallæ is abandoned as too hopelessly large. They are mostly long-legged marsh or coast birds, generally with long legs and bills. Their distribution is very wide, the four largest families (rails, snipes, plovers, and herons) being quite cosmopolitan.

Gram. See CHICK PEA.

Gramineæ. See GRASSES.

Grammar deals with the usage of some one form of speech. It may be described as a section of the larger science of language (see article PHILOLOGY), which treats of the origin, development, and general character of the principal families of language and of human speech as a whole. In common use, however, grammar means not a branch of science, but a treatise on some one well-defined form of speech as used in the present day, as by French grammar we mean a book on the usage of Paris; by English grammar we mean an account of the language spoken and written by educated men throughout Great Britain, which language, however, is only one dialect of English speech, the East Midland. That dialect by favouring conditions has superseded the other dialects, southern and northern, which were once spoken and written, and are still in a lessening degree spoken, in different parts of the island.

Grammar has two parts. The first describes the forms of a language, the single words which occur in it, its nouns, verbs, &c.; and its modifications of such forms, the cases of its nouns, the persons and tenses of its verbs, &c., used to express modifications of the same idea, as 'child,' 'child's,' 'children,' 'spring,' 'sprang,' 'sprung,' in English. This is called the morphology of a language, or (more loosely) its etymology. The second part deals with the use of these forms in combination: their syntax—i.e. their arrangement in order of speech. The general principles of this will vary little in the different languages of the same family; but each language has its idioms, as we call them, its own special refinements of usage, and it is in the clear discrimination of these that the practical value of a grammar lies.

Grammar in this function may be called special. It does not enter into the history of the forms which it describes; it is sufficient if it sets forth what they are at a particular time, without showing how they became such. But it is possible to a considerable extent to trace the history of these forms—e.g. we can see how literary English has developed out of the English of Chaucer, and that from the English of an earlier day, how the forms have changed mostly in the direction of uniformity, and how (to a lesser degree) their syntax has altered. To trace this belongs to historical grammar, and some of the results of this science are now commonly given in

each special grammar. Lastly we can compare together the forms and usage of cognate dialects. We can compare, e.g., the grammar of our literary English dialect and that of the speech of Dorset, as set forth by Mr Barnes; and, employing the results of historical grammar, we can trace back the varying development of English speech as a whole; or we can compare the development and trace the connection of English and of German speech, and the relation of each of these to Latin or to Greek, till we arrive at some knowledge of a common speech of which all these are only derived forms. This is the work of comparative grammar.

Naturally, we do not learn our own speech from a written grammar. A child learns his words and their use from those around him, not as a whole, but one by one; and he forms new words for himself on the analogy of those he has already acquired. When he finds that any of these formations are not used by others he rejects them, and so he assimilates his speech to that of those around him. It is when we have to deal with a speech which is not our own, either that of a foreign nation, or of our own language at some earlier period, or of some dialect of our own language, that we need a grammar. The earliest works on grammar were due to the second of these causes. At Alexandria, the great commercial and literary centre of Greece in the days when the separate Greek states had ceased to be autonomous, there was for the first time a huge collection of the works of earlier writers, especially the Homeric poems. The age was one destitute of original ability; the loss of freedom had caused the loss of the motives which had produced the literature of the past. But it contained a large number of literary men, whose activity was chiefly spent on the work of their predecessors. This was to them in language and in style archaic; it required glosses—as we should say, glossaries—and explanations of disused forms. Hence arose the first grammarians, men often of conspicuous ability in their own line, such as Zenodotus and Aristarchus. At a later time, Romans who wished to learn Greek had grammars based upon Greek models, compiled for them in Latin, and these have been the parents of all European grammars to the present day. The grammatical terms with which we are familiar are consequently in the main Latin translations of Greek originals, and because of this they are often less intelligible than they might be.

It is to the Greeks that we owe the number of the so-called 'parts of speech.' But their eight were not the same as ours. They had (1) the noun; (2) the verb (terms which go back to Aristotle, though in his use the 'verb' meant all that is logically called the predicate); (3) the participle, so called because it partook of the nature of both the noun and the verb—it was a noun in form, yet it governed a case like a verb; (4) the article; (5) the pronoun; (6) the preposition, so called not as being placed before a case, but as set before a verb or noun in composition; (7) the adverb—i.e. the 'additional predication,' not anything specially belonging to the verb, as the Latin name seems to imply; (8) the conjunction. The Romans modified this list. First, they rejected the participle, and supplied its place by dividing the noun into the substantive and the adjective; this is a gain to logic, but as a matter of history the two go back to the same origin. The thing and the quality of the thing were alike expressed by the noun, and the analogic feeling in man suggested that they should be represented when together by nouns of the same class—i.e. with the same terminations: hence we have the grammatical property called gender, which is altogether independent of natural gender. Secondly, they rejected the article in their grammar, not having it in their speech. Here they were historically right, for the Greek article was only a pronoun. Later Latin developed a new one out of a different pronoun, *ille*, seen in various forms in the different Romance languages—French, Italian, Spanish, &c. But having lost the article they felt bound to fill up its place: therefore they put in the interjection, which is the conventional stereotyped expression of the natural cries which, we may believe, in days before articulate speech existed, eked out the earliest and simplest means of communication—i.e. gestures (see article PHILOLOGY). The interjection is therefore no 'part of speech;' it is an imperfect undeveloped 'speech whole;' and the Greeks rightly did not include it in their list.

If we exclude the interjection, we can prove by means of historical grammar that these different parts of speech run back to two, the noun and the verb; and the distinction even of these rests on the inability of our analysis to separate them completely. It is true that nouns are distinguished by 'case-suffixes'—*lupus*, *lupum*, *lupi*, *lupo*, &c. in Latin; and the verb by 'personal suffixes'—*amo*, *amas*, *amat*, &c.; but there was doubtless a time in our parent-speech when no such 'suffixes' existed, and all that lies behind them may have been in those earlier days identical for noun and verb. Our own language shows the possibility of using one form—e.g. 'love,' alike for noun and verb. The pronoun differs from the noun in meaning by its greater generality. 'This' includes all objects in our immediate neighbourhood, books, chairs, tables, &c.; 'he' includes all 'Johns,' 'Smiths,' &c. In form it differs only by the simpler and on the whole the more archaic character of its root or ultimate element. The term 'pronoun' expresses only one subordinate use—the anaphoric or 'reference' use, by virtue of which, having once uttered a man's differentiating name, 'John,' or the like, we refer to him afterwards, so long as clearness permits, only as 'he.' The origin of adverbs and prepositions out of nouns or pronouns is very obvious in our own language: 'once' is Old Eng. *ānes*, the genitive of *ān* ('one'); 'seldom' is an old dative plural of *seld* ('rare'); to go 'afoot' was to go 'on' foot; 'beside' is 'by side (of);' and, if we are unable to reach the original form of prepositions like 'on' and 'by,' we do not doubt that in days beyond our analysis they were nouns modifying other words which then filled the place of the nouns and verbs of later times. Similarly, conjunctions are either noun-cases or condensed sentences; 'whil-s-t' is 'whiles,' the genitive of 'while' (time), with a final *t*, which may be analogous to that of 'lest' (another conjunction), originally 'thī less the,' then 'lesthe,' and 'leste;' 'howbeit,' 'because' (by cause of) explain themselves. Thus the eight parts of speech may be traced back to not more than two.

All language at all times of which we have any knowledge, and doubtless from the very beginning of human speech, is a modification of existing combinations of sound. Language probably began, as has been already suggested, with the use of cries to help out gestures. These cries were associated by use with particular ideas, and that most elementary language (or languages, for there is no need to suppose that language sprang up in one place only, the circumstances being everywhere similar) was subject to the same laws which mould our speech at the present day. Groups of sound expressing the required thought are combined together, as 'man' and 'kind,' or 'house' and 'top.' The combination may be such that the different parts are always separable; then each

sound-group (or word, as we may now call it) remains intact, and the relation which one word bears to another in the expression of the entire thought depends on the position of the words, the stress, or the pitch of the voice with which each is pronounced, or other more minute conditions. A language of which this is the prevailing character is called 'isolating,' and Chinese is the best-known type. It seems inadequate, yet the facility with which ideas can be expressed in such a language may be seen from the different grammatical values which the same sound-group can have in our own language in phrases like 'love is sweet,' 'we feel love,' 'God is love,' 'I love you,' &c.

But nearly all languages admit of combination more complete than this, whereby two or more words can be joined together, so that a single sound-complex expresses two or more ideas in combination—e.g. 'free-man,' 'black-bird,' 'thank-ful,' 'high-born,' 'back-bite,' 'ill-treat,' &c. Each of these may form the model for numerous copies; thus, 'thankful' can produce 'youthful,' 'healthful,' which are later English compounds. Then came hybrid compounds, where the first member is of Latin origin (of course through the Norman), as 'merciful,' 'masterful.' In this last we see that the exact nature of the original compound is obscured, and that 'ful' gives merely the additional sense of 'like,' as though the compound had been 'masterlike,' which does indeed occur in a briefer form, and with a secondary sense, as 'masterly.' This example throws light on the history of all word-formation. A word may cease to be felt as a compound commonly through change of form in one or both of its parts, as 'masterly,' where the idea of the skill of a master in some art alone remains; or 'hussy' (house-wife), where both parts of the compound are lost. Sometimes only one syllable may remain, as in 'lord' (loaf-ward). Often some great change of idea joins with phonetic change in obscuring the nature of a compound, as in fortnight (fourteen-night). Now, when the last part of the compound fulfils certain conditions, it may be used in the formation of countless other words: *-lic* (like), which is found in O. E. in 'eorth-lic,' 'cyne-lic' (earthly, kingly), passes on in its simpler form *-ly* in 'daily,' 'princely,' &c.; and *-ly* is then what grammarians call a suffix, an element which cannot be used alone, but can be added on at pleasure to another word to modify its meaning. The conditions are (1) that the form of the so-called suffix must be a convenient one phonetically; (2) that it must have been in use in a considerable number of compounds at the same time: for 'bridegroom' (bride-man), 'nightingale' (*nihte-gale*, night-singer), 'gossip' (*God-sib*, God-related) have produced no analogous forms in English owing to the rarity of the use of their second member; (3) that the last member must be general in its sense, or at least acquire some general sense in composition. A suffix is especially favoured which can be mentally referred to some common word of general sense, though it may really have nothing to do with that word. Thus, in 'credible,' 'invincible,' &c. the original suffix *-ble* (*-bili* in Latin) is seen; but in many words which come to us through the French, 'probable,' 'amiable,' *a* preceded the last syllable: thus these words seemed to mean 'able' to be proved, or to be loved; and so words like 'knowable,' 'lovable,' 'reliable' sprang up in abundance. Independently of these conditions of the origin of suffixes, it is also necessary that the first member of a compound remain unobscured. Thus, no words have been formed on the model of 'orchard' (*wort-yard*), though *-ard* as a Norman-French suffix has produced derivatives like 'drunkard,' on the analogy of 'bastard,' 'wizard.'

We are justified in inferring from the English suffixes which can be explained as remnants of words (*-ful*, *-ly*, *-dom*, *-hood*, and the like) that the others whose history can no longer be traced had a similar origin; and even in extending this principle to those formative suffixes which reach back to the earliest period of language. It is a sound axiom that what is in language has been and will be; it is only by dealing with spoken languages that we can infer the nature of those known to us by tradition only. It cannot be said with certainty that we should assign the same origin to those other suffixes—which we call inflectional—to which we owe the cases of our nouns, and the persons, tenses, and voices of our verbs. The persons, indeed, of the verbs were, it is most probable, pronouns. The *m* in 'am' represents original 'I,' so 'am' meant 'exist I,' and was a compound of two words, originally as separate as 'I exist;' *s* represented 'thou,' and *t* (Eng. *th* in 'loveth,' &c.) was 'he.' But we cannot say exactly what the tense-suffixes were, though we believe they are the remnants of words; nor what were the case-suffixes of the nouns—what, for example, was the *s* which still marks our genitive case, or the *s* of our plurals. But we know that we can make a 'noun of multitude' by making such a compound as 'man-kind,' and there is no reason why *-es* (the original form of *-s*, our plural suffix) may not once have been some such word as 'kind,' and compounded in the same manner. Such a history is in accordance with all we know of the processes of language.

It will be apparent from what has been said that there never was in any language some one period in which its suffixes were made, succeeded by a period in which there was no more growth but only decay. Formation is always going on, though more slowly in languages which are stereotyped by literature. In English we have almost ceased to use our second personal suffix *-st*, in 'lovest,' &c. But that *st* is itself an English growth: the older English form was *s:* in the old Mercian Psalter (edited by Mr Sweet in his *Oldest English Texts*) we find both 'thu dydes' and 'thu dydest,' 'thu bis' and 'thu bist,' &c. Other Teutonic languages show the same (independent) development. Still more do 'formative suffixes' go on growing. One of our commoner English suffixes (used to make a diminutive) is *-let*, seen in comparatively recent words, like 'brooklet,' 'streamlet,' &c. But the form is really a development of the older *-et* (the French *-ette*) in 'helmet,' 'banneret,' 'cygnet.' Several of these forms, like 'islet,' 'circlet,' and 'eaglet,' were formed out of nouns which ended in *l;* and so new ones were formed—'ring-let,' &c., as though the *l* had always belonged to the suffix. We are getting a new suffix in *-nist*, seen in 'tobacco-nist,' &c. This is an extension of the old suffix (Greek, through Latin into French) *-ist*, in 'jurist,' 'dentist,' &c.; this seems to be due to words where the *n* belongs to the root-part, as 'mechan-ist,' 'pian-ist,' and other late forms.

A common method of inflection in language is, not by suffix, but by change of the original vowel: thus, we have 'man,' but plural 'men;' and in verbs we find present 'drink,' preterite 'drank,' past participle 'drunken.' These can, however, be traced to the influence in different ways of lost suffixes. Thus, the old declension of 'man' was nom. 'mann;' gen. 'mannes;' dat. 'menn(i);' plur. nom. 'menn(i);' gen. 'manna;' dat. 'mannum.' It is clear that the change of *a* to *e* had at first nothing to do with the plural, for it is found in singular and plural alike when *i* followed: this vowel had the property of modifying *a* in a preceding syllable to *e*. But when the cases were lost, as happened in English mainly through Norman

influence, 'man' remained as the only singular form, and 'men' as the only plural; so, for grammatical purposes, the plural might truly be said to be made by changing *a* to *e*. Similar is the history of 'mouse,' plur. 'mice;' 'goose,' plur. 'geese,' &c. The verb change, *i*, *a*, *u*, has a most symmetrical look, and seems as though it must have been devised to express the change of relation. As a fact, however, in this and all similar cases, *i* and *u* represent in all Germanic languages original *e* and *o*; and these two vowels probably represent developments of a minute variation in pitch-accent (*e* being higher than *o*), dating from beyond the historic period of the parent-speech; and this variation marks indeed tense distinctions—e.g. in Greek, pres. *dérkomai*, perf. *dédorka*; but it is also found in nouns such as *génos*, *gónos*, and it seems to have had nothing to do with tenses at first. The second change, that in 'drank,' 'drunken,' has quite a different origin, but one equally removed from tense-formation. Like the first variation, it represents a very ancient change—due to the fact that in the parent language the syllables immediately preceding or following that which bore the stress-accent were weakened: no language shows better than English how to slur a syllable immediately preceding or following a stressed one—e.g. in 'alone' (where the last syllable is stressed) the *a*, originally the full *a* of 'all,' is sounded like the *u* of 'but,' or the *o* of 'son;' the same sound is commonly heard—e.g. in such a word as 'liberty,' instead of the *e* of the middle syllable, the stress being on the first. Now in the past participle the stress was on the suffix *-no* (seen as *-en* in 'drunken'), and hence the vowel-change in the root. But it oddly happens that just the same change took place in the plural of the perfect itself, owing to the plural personal suffixes being stressed in the parent language; and so the Old English singular third person was 'drank,' but the third plural was 'druncon' (a precisely parallel case is the Greek sing. *oida*, plur. *idmen*, orig. *idmen*). So there was a time when it was right to say 'I drank' and 'we drunk;' but a meaningless distinction like this could not be maintained: one form was bound to supplant the other, and 'drank' won; but 'won,' the plur. of 'winnan,' supplanted the sing. 'wann;' 'stung' beat 'stang;' 'sprang' and 'sprung' were used indifferently at the beginning of this century, as by Scott and Byron, to help their rhymes; and here and in other verbs there is still some fluctuation of use, even among educated men. These examples may suffice to show that vowel-change, though extremely useful to mark grammatical distinctions, was not in anyway designed for this end, which has been reached by unconscious differentiation: for we may infer from what we can observe in languages whose history can be traced that the prehistoric distinctions in the earliest recorded languages had a like accidental origin.

The history of grammatical forms may then be roughly sketched thus. They arose probably always from composition. Such compounds were subject to phonetic corruption, and the unstressed syllables were slurred and lost their individuality; or one member of the compound ceased to be used independently, some other word having superseded it, the result being the same as in the first case—viz. the loss of special significance in one part of the compound; and when the part so generalised is the final syllable, that syllable becomes a mere suffix, and can express relation, as the *-ly* in 'fatherly,' or the *-s* in 'fathers.' Furthermore, the cases of the nouns and the persons of the verbs thus formed were liable to variations of form in the same noun or verb, due to the incidence of stress or the influence of one syllable on another. The irregularities thus produced were again levelled in process of time by the natural tendency to do away with differences which are no longer significant; hence came symmetry of inflection, which is not the earliest stage in grammar, but rather the result of long unconscious play of physical and mental forces. Again, inflections constantly perished, either by simple phonetic decay, or more commonly through change of nationality, as, for example, when the Teutonic and other races adopted the Latin of the conquered Roman provinces, or when the descendants of the Normans began to use the national speech of England. Thus arises much simplification of what is to the speakers a foreign grammar; also there is a great growth of hybrid forms, Norman-French words combining with English suffixes, and *vice versâ*. With the dying out of inflections arises a great growth of indeclinable words—adverbs, conjunctions, and prepositions: some cases, as the locative or the ablative in Greek, or the instrumental in Latin, became almost extinct; the few surviving forms, as Greek locatives in *-ei* and ablatives in *-os*, belonging to nouns of the *o* class, lost their connection with those nouns; they remained isolated forms, freed from the levelling tendencies which affected the other cases of the same noun, because no longer felt to be in connection with them. Thus they could become the origin each of a new group of forms, extending (as did the so-called Greek adverbs in *-ei* and *-ōs*) to many other classes of nouns besides that which gave them birth. Very commonly this isolation of some particular form may arise while the case is still in full use, through some accidental break of connection. In English our one surviving case-form in the genitive is *-s*, yet this very form has been the parent of numerous adverbs: 'ānes' (already mentioned) was the genitive of 'ān' (one): the connection was lost, and the adverb 'once' arose, and produced 'twice' (older form 'twi-es'), 'thrice' by mere analogy, no such genitives having ever existed; so, too, 'forward-s,' 'alway-s,' and many others are analogical forms—no true genitives, but copies of the model set by an isolated genitive. It has been well said by one of the greatest of modern German philologists, Professor H. Paul, that isolation is the essential condition of all speech-development.

Lastly, even while cases survive in use, it is necessary to supplement them by prepositions, because (except perhaps in languages which, like the Finnish, have fifteen cases) there are not enough case-forms to express the numerous relations in space ('to,' 'from,' 'in,' 'upon,' 'by,' 'near,' 'with,' &c.) in which one person or thing may stand to another. As cases die out this need increases, and modern European languages express practically all relations by prepositions. This principle is sometimes called analysis, as contrasted with the combinatory 'synthetic' principle of older forms of languages. Naturally no language is ever completely analytic: even in English words like 'father's' and 'love's' still attest that the language was once synthetic.

Those who desire fuller insight into the principles of grammar (as seen in languages of the Indo-European type) may consult the well known works of Prof. Max Müller; A. H. Sayce's *Principles of Comparative Philology*, and his *Introduction to the Science of Language*, which treat the subject from a different standpoint; W. D. Whitney's *Life and Growth of Language*, and his *Linguistic Studies*; H. Paul's *Principien der Sprachgeschichte*, an invaluable but difficult work, translated, though not made materially easier, by Prof. Strong. A synoptic view of the relation of the Indo-European languages will be found in the still unfinished *Grundriss der vergleichenden Grammatik* of Karl Brugmann (vol. i.

trans. by Wright). Excellent works on special languages are Whitney's Sanskrit Grammar and Delbruck's *Altindische Syntax*; for Greek, may be mentioned (out of many) Brugmann's Grammar in J. Müller's *Handbuch der klassischen Altertumswissenschaft*, and D. B. Monro's *Homeric Grammar*—a most suggestive book; for Latin, Stolz's Grammar (also in Müller's *Handbuch*), and Dräger's *Historical Latin Syntax*, which, though old, is still the most systematic work on the subject; innumerable valuable articles bearing on both Greek and Latin are to be found in Kuhn's *Zeitschrift*, Bezzenberger's *Beiträge*, the *Mémoires de la Société de Linguistique*, the Cambridge and the American Journals of Philology; for Keltic, the Grammars of Zeuss and Windisch (Old Irish, trans. by Dr N. Moore), and Prof. Rhys's Lectures on Welsh Philology; for the Romance languages collectively, the Grammar of Diez and the (still unfinished) *Grundriss der romanischen Philologie* of G. Grober; special works on these languages are too numerous to mention. For Teutonic languages there is an excellent series of grammars published by Niemeyer (Halle), on Icelandic by Noreen, on Old High German by Braune, and on Middle High German by Paul (Strong and K. Meyer's *History of the German Language* may also be found useful); on Gothic, Braune; see also Douse's *Ulfilas*, and Prof. Skeat's little edition of the Gospel of St Mark in Gothic. For English, Sweet's *Anglo-Saxon Reader* and Cook's trans. of Sievers' Grammar of Old English are the best; Prof. Skeat's *Principles of English Etymology* should also be consulted; Storm's *Englische Philologie* is excellent, but still a fragment; A. J. Ellis' *Early English Pronunciation* (5 vols. 1869 89) is a mine of information on the history of the English language.

Grammar-schools. See EDUCATION.

Gramme is the standard unit of French measures of weight, and is the weight of a cubic centimètre of distilled water at 0° Centigrade (corresponding to 32° F.); the other weights have received names corresponding to the number of grammes they contain, or the number of times they are contained in a gramme (see DECIMAL SYSTEM, METRIC SYSTEM). A gramme = 15·43248 grains troy, from which the equivalents in English measure for the other weights can easily be found; thus:

	Grains Troy.		Lbs. Avoirdupois.	
Centigramme =	·1543234	=	·0000220462	
Decigramme =	1·543234	=	·000220462	
GRAMME =	15·43234	=	·0022046	
Decagramme =	154·3234	=	·022046	
Hectogramme =	1543·234	=	·220462	
Kilogramme =	15432·34	=	2·20462	
Myriagramme =	154323·4	=	22·0462	= ·19684 cwt.
Quintal (q.v.) =	1543234	=	220·462	= 1 9684 "

GRAMME-ATOM.—A quantity of an elementary substance, such that the number of grammes-weight is the same as the atomic number of the element—e.g. 12 grammes of carbon (C=12).

GRAMME-EQUIVALENT.—A number of grammes-weight of a substance, elementary or compound, equal numerically to the quantity of that substance which is chemically equivalent to unit weight of hydrogen—e.g. 8 grammes of oxygen, 9 grammes of water.

GRAMME-MOLECULE.—A quantity of a substance, elementary or compound, such that the number of grammes and the molecular weight are numerically the same—e.g. 32 grammes of oxygen (O_2=32), 18 grammes of water (H_2O=18).

Grammiche'le, a town of Sicily, 33 miles SW. of Catania, on a mountain-ridge, 1768 feet above sea-level. Beautiful marbles are produced in the neighbourhood. It was founded in 1693 in place of the neighbouring town of Ochiolà, which had been destroyed by an earthquake. Pop. 11,804.

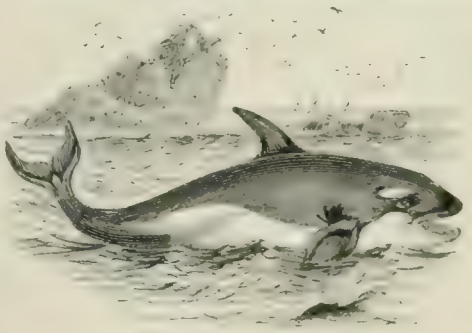
Grammont (Fr.; Belg. *Geeraerdsbergen*), a small town in the Belgian province of East Flanders, on the Dender, 14 miles by rail S. by E. of Ghent, with an episcopal seminary, and famous manufactures of black lace. Pop. 9836.

Gramont, or GRAMMONT, PHILIBERT, COMTE DE, a celebrated French courtier, was born in 1621. His grandfather was husband to 'la belle Corisande,' one of the many mistresses of Henry IV. While still very young he distinguished himself as a volunteer under Condé and Turenne, and quickly became a favourite at the court of Louis XIV., from his handsome figure, lively wit, and wonderful luck at play. But his gallantries brought him exile from France in 1662. He found a pleasant refuge and congenial society among the merry profligates that thronged the court of Charles II. of England. Here he took his share in all the intrigues that formed the sole occupation of those gilded reprobates of both sexes who modelled their morals on the king's. He married, but not without compulsion, Elizabeth Hamilton, sister of Count Anthony Hamilton, with whom he afterwards returned to France, there to live as he had lived in England. Ninon de l'Enclos said he was the only old man who could affect the follies of youth without being ridiculous. At eighty he inspired his memoirs or at least revised them when written by his brother-in-law, Anthony Hamilton (1646–1720). This strange book is a remarkable revelation of a world of intrigue and villainy, saved from detestation only by its brilliancy and wit. It is written with equal grace and vigour, and its portraits are among the best materials for the domestic history of the time. Gramont survived till 1707. His *Mémoires* was first printed anonymously in 1713, and an English translation by Boyer was published in 1714. The work, though actually the composition of a foreigner, is an acknowledged French classic, and has often been reprinted, sometimes in forms as sumptuous as the editions by Renouard (1812) and Gustave Brunet (1859). The best English editions are Edwards's (1793), Malleville's (1811), Bohn's (1846), and that published by John C. Nimmo in 1889.

Grampians, a name very loosely applied to the mountain-system of the Scottish Highlands. Some, for instance, restrict it to a 'chain' of heights bordering the Lowland plain from Dumbarton to Stonehaven, whilst others include a 'range' extending from Stonehaven to Ben Nevis, as well as the Cairngorm group, Schiehallion, &c. Hector Boece adopted the name in 1527 from Tacitus's *Mons Grampius* or *Granpius*, the scene in 86 A.D. of Agricola's crushing defeat of Galgacus. Where that battle was fought has itself been hotly contested. Ardoch, Dalginross, near Comrie, and Urie, near Stonehaven, are sites named, also the junction of the Isla and Tay. See also VICTORIA.

Grampound, a decayed Cornish village, till 1824 returning two members to parliament, 7 miles SW. of St Austell. Pop. 495.

Grampus (a sailor's corruption of Ital. *gran*



Grampus (*Orca gladiator*).

pesce, or Span. *gran pez*, 'great fish'), a cetaceous animal, common in almost all seas from Greenland

to Tasmania, not unfrequent in the Atlantic, and well known on the British coasts. Constituting the genus Orca, it is the largest of the Delphinidæ, often more than 20 feet in length; its form spindle-shaped, but thicker in proportion than the porpoise, from which it also differs in the much greater height of its dorsal fin, in its rounded head, and its permanent conical teeth. It is remarkable for its great strength and voracity, and is the only cetacean which preys systematically on its warm-blooded kindred—on small dolphins and porpoises, belugas, and even whales—the grampuses, or 'killers' as English sailors also call them, assembling in herds to pursue whales.

Gran, a royal free-town of Hungary, is situated on the right bank of the Danube, here crossed by a bridge of boats, 25 miles NW. of Pesth, and opposite the mouth of the river Gran (length, 150 miles). The town is the see of the primate of Hungary, and its great domed cathedral (1821–56), on the castle hill, rivals in its magnificent proportions St Peter's at Rome. The palace of the prince-archbishop, who is primate of Hungary, and has a rent roll of £80,000, is the chief of many buildings in connection with the cathedral. The warm mineral springs of Gran have also some fame. Pop. (1890) 9349. Gran was the cradle of Christianity in Hungary; here St Stephen, the first king, was born in 979, and baptised and crowned in 1000. In the next two centuries it became the greatest commercial town in the kingdom; the old name, *Istrogranum* ('Danube grain-town'), appears now in the Magyar *Esztergom*, and the Hungarian-Latin *Strigonium*. Gran's fortunes never recovered from the storming by the Tartars in 1241.

Granada, an ancient Moorish kingdom of Spain, embracing the south-eastern portion of Andalusia, and now divided into the three modern provinces of Granada, Almeria, and Malaga, the united areas of which amount to 11,062 sq. m., and the united pop. (1877) 1,328,464; (1887) 1,361,456. Except in the narrow strip of coast region along the Mediterranean, the surface is a succession of mountain and plateau rising in the centre to the snow-capped Sierra Nevada; but the soil is fertile, and the ancient Granada, which became an independent kingdom after the fall of the caliphate of Cordova in 1236, supported a population of 3 millions, and sent 100,000 men into the field. From 1246 the Moorish kings were obliged to recognise the supremacy of the kings of Castile. A quarrel, however, which arose between the vassal king of Granada and Ferdinand and Isabella in the 15th century resulted in a war of eleven years' duration, the result of which was the complete conquest of Granada by the Spaniards in 1492, and the total destruction of Moorish authority in Spain.

The modern province of Granada has an area of 4928 sq. m., which includes the highest mountains in the Peninsula, and one of the most picturesque regions in Europe. A great portion belongs to the basins of the Jenil and the Fardes (Guadiana Menor), tributaries of the Guadalquivir; the Guadalfeo and other streams flow into the Mediterranean. The climate is warm, but tempered by the snow-clad mountain-ranges; the fruitful soil yields the products of both the temperate and subtropical zones. Neither the mineral springs nor the rich deposits of salt, iron, lead, copper, zinc, sulphur, marble, and alabaster are much worked; the silk industry, formerly important, has nearly disappeared, and the manufactures are now chiefly weaving, sugar and brandy refining, &c.; and the trade of the province, hindered by a rock-bound, inhospitable coast and the absence of roads, is unimportant. Pop. (1877) 479,066; (1887) 480,594.

GRANADA, the chief town of the province, and formerly capital of the kingdom, has sadly declined since the days of its Moorish masters, but still ranks as one of the larger cities of Spain. It lies at the foot of the Sierra Nevada, on and between two hills, the southernmost being the site of the famous Alhambra (q.v.), and is 2245 feet above sea-level, and 126 (by rail 179) miles E. by S. of Seville. It overlooks a fertile and extensive plain, and stands on the right bank of the Jenil, which is here joined by the Darro. The northern hill is occupied by the Albaicin, the oldest part of the town. The main part of the town lies in the plain to the west of this, on both sides of the Darro, which is here mostly arched over; and the wide suburbs of Elvira and Antiqueruela stretch farther to the west and north. The modern town is commonplace and dull, with wide streets, open squares, and many-windowed houses; but the old houses, with their flat roofs, turrets, many-coloured awnings, balconies, and fountains, preserve still a half oriental aspect, and the labyrinths of narrow, tortuous, ill-paved lanes that for the most part pass for streets here and there offer picturesque views. The chief centres of commercial activity are the old and handsome square known as the Vivarrambla and the Zacatin, or old bazaar, a street which still retains much of the Moorish style. On the outskirts of the town there is a shady Alameda. Granada is the seat of an archbishop, and has a university (1531) attended by nearly 1000 students. The cathedral, begun in 1529, is profusely decorated with jaspers and coloured marbles, and contains the tombs of Ferdinand and Isabella, and of Philip I. and his consort Juana, fine specimens of Italian Renaissance sculpture, doubtfully attributed to Torrigiano. In the monastery of San Geronimo the 'Great Captain,' Gonsalvo di Cordova, is buried. The industry and trade of the town are inconsiderable. Pop. (1877) 76,108; (1887) 66,778. The modern city of Granada was founded by the Moors in the 8th century, not far from the ruins of an ancient Celtiberian town, Illiberis, and rapidly rose to distinction as a wealthy trading city and as a seat of arts and architecture. According to the common account, about 1350 the pop. numbered 200,000, and at the time of the Spanish conquest reached 400,000; the city was surrounded by a wall fortified with 1030 towers, contained 70 libraries, and was the seat of 50 schools of learning. But this is more or less legendary.—The etymology of Granada is doubtful, but the worst explanation is that which makes the name mean pomegranate. The Moors called it *Karnattah* or *Karnattah-al-Yahoud*—i.e. Granada of the Jews, to whom this quarter of the early town was given up, the Arabs retaining Illiberis, which they called Elvira. Karnattah possibly signifies the hill or city of strangers. See Prescott's *Ferdinand and Isabella* (1837); Washington Irving's *Conquest of Granada* (1829); Lafuente y Alcantara, *Historia de Granada* (4 vols. Gran. 1843).

Granada, a department and city of Nicaragua. The department, lying between the Pacific and Lakes Nicaragua and Managua, has an area of nearly 2600 sq. m.; it is mostly a level savannah, but contains the volcano of Masaya and the Mombacho peak (4500 feet). Pop. about 70,000.—The city stands on the north-west side of Lake Nicaragua, and is connected with Managua by rail. Founded in 1522, it was formerly the chief town of the republic, but has suffered greatly from the civil wars; it is still, however, of some importance as a trading centre. Pop. about 10,000.

Granadilla, the edible fruit of *Passiflora quadrangularis*. See PASSION-FLOWER.

Granby, JOHN MANNERS, MARQUIS OF, an English general, the eldest son of the third Duke

of Rutland, was born January 2, 1721. He entered the army, and soon after attaining the rank of lieutenant-general (1759) was sent to Germany as second in command, under Lord George Sackville, of the British troops co-operating with the king of Prussia. After the battle of Minden he was appointed commander-in-chief of the British troops, and held that post during the remainder of the Seven Years' War. After the peace of 1763 he was constituted master-general of the ordnance, and in 1766 commander-in-chief of the army. He died at Scarborough 19th October 1770. Though very popular in his time, as is evidenced by the frequency with which his portrait was a public-house sign, he was the subject of some of Junius's most terrible invectives. His military qualities appear to have been overrated. See Life by W. E. Manners (1899).

Gran Chaco, an extensive central tract of South America, extending from the southern tropic to 29° S. lat., and bounded on the E. by the Paraguay and Paraná, and on the W. by the Argentine provinces of Santiago del Estero and Salta. Its area, about 180,000 sq. m., exceeds that of Great Britain and Ireland by one-half. The portion south of the Pilcomayo belongs to Argentinia, and the remaining third to Paraguay; but the possession of the upper section of the Pilcomayo is disputed by Bolivia. The country rises gradually from the Paraná towards the north-west as far as 25° 40′ S. lat., when it dips to the valley of the San Francisco —part of a great depression extending through Bolivia nearly to the frontier of Peru, and subject to annual inundations. The Chaco is watered principally by two long, narrow, and tortuous streams, the Bermejo and the Pilcomayo, flowing south-east in courses generally parallel, and about 180 miles distant from each other. Only the former has been explored throughout, but it is known that both possess an unusual number of obstructions, though these are quite removable, consisting mainly of shallows caused by the compact argillaceous bed which is a geological characteristic of the whole Chaco subsoil. The bed of the Bermejo also oscillates backward and forward, and in 1870–72 the river opened up a new channel (known as the Teuco) for nearly 200 miles. The most northern part of the Chaco is an extremely arid zone, but the banks of the upper Pilcomayo are fertile and its sands auriferous. To the north of the Bermejo there are numerous and wide marshes and stretches of jungle, drained by many small streams; but the land is well wooded, chiefly with vast seas of palms (here an indication, however, of marshy lands subject to inundation, as the local algaroba is of dry, high land), while south of the Bermejo the primeval forest extends into Salta. The annual rainfall is probably 80 inches, all concentrated into the six months from November to May; then wide sections become almost a lake district, whilst in seasons of extraordinary floods the Paraguay and the other great rivers create a vaster sea than the Nile. Thus much of the region is of modern alluvial formation, and exceedingly fertile. A very dry season succeeds, and some districts are then utterly waterless, or the wells that have been sunk are impregnated with salt. The average temperature is 80° F.; the climate is said to be equable, and in the southern section suitable to colonists of the Anglo-Saxon race. Since 1537, when the first explorer, Captain Juan de Ayolas, marched with 250 men into the wilderness from which none ever returned, numerous expeditions have been sent out from the surrounding countries; but the savage tribes (still unsubdued throughout the unexplored interior), swamps, lagoons, and floods defeated all early attempts to open up the country. In 1884 garrisons were established along the Bermejo, and since 1885 permanent settlements have been made. Already there are many agricultural colonies and small towns along the Paraguay, connected by rail and telegraph; the Bermejo lands, on both banks for 400 miles from its mouth, have been conceded by the Argentine government for various enterprises; thousands of hands are employed in the timber trade, and steam sawmills are in operation; cattle-raising and farming are carried on, and from the sugar-cane refined sugar and rum are manufactured. Concessions also have been granted for railways from Corrientes to the Bolivian frontier. See an interesting paper by Captain John Page in *Proc. Roy. Geog. Soc.* (1889).—*Chacu,* the Quichua word for 'hunt,' may refer to the great Indian *battues;* but under the Incas it was applied to the numbering of flocks, and so came to signify wealth —*Gran Chaco* thus meaning 'great riches.'

Grand-combe, La, a town in the French department of Gard, 41 miles NNW. of Nimes. Near it are very important collieries. Pop. 6111.

Grandees (Span. *grandes*), since the 13th century the most highly privileged class of nobility in the kingdom of Castile, in which the members of the royal family were included. Their honours were hereditary; they held lands from the crown on the tenure of military service, were exempted from taxation, could not be summoned before any civil or criminal judge without a special warrant from the king, and could leave the kingdom, and even enter the service of a foreign prince at war with Castile, without incurring the penalties of treason. Besides this, they had the right of being covered in the presence of the king. In the national assemblies they sat immediately behind the prelates and before the titled nobility (*titulados*). Under Ferdinand and Isabella they were deprived of most of their peculiar privileges; and Charles V. converted them from an independent feudal nobility into a dependent court nobility. Under Joseph Bonaparte their dignities and privileges were entirely abolished; but they were partially regranted at the subsequent restoration. Grandees are still members of the senate in their own right.

Grand Forks, capital of Grand Forks county, North Dakota, on the Red River of the North, opposite the mouth of Red Lake River, is about 55 miles N. of Fargo, at the intersection of two railways. It has several flour and saw mills, iron-works, and a brewery, besides a large transit trade in wheat. Pop. 4979.

Grand Haven, capital of Ottawa county, Michigan, on Lake Michigan, and on the south bank of Grand River, 31 miles W. by N. of Grand Rapids by rail. It has a good harbour, with two lighthouses, and ships large quantities of lumber and grain. It contains several lumber-mills and manufactories of wooden wares, &c.; and a medicinal spring renders the place a summer-resort. Pop. 5914.

Grand Jury. See Jury.

Grand Pensionary. See Pensionary.

Grandpré, a village in the French department of Ardennes, on the river Aire, 40 miles NNE. of Châlons. Here on 14th September 1792 Dumouriez was defeated by the Allies.

Grand Rapids, capital of Kent county, Michigan, stands at the head of steamboat navigation on Grand River, here crossed by six bridges, and at the junction of several railways, 60 miles WNW. of Lansing. The river, which enters Lake Michigan 40 miles below, here falls 18 feet in a mile, and across it extend the rapids which give name to the town. Conducted by canals, it

supplies motive-power to numerous sawmills and manufactories of furniture and wooden ware, farming implements, flour, machinery, &c., though steam is now in use in most of the factories: gypsum quarries near the town supply abundant material for stucco plaster and kindred preparations. White bricks are also largely made here, and many of the houses and churches are built of these. The city is the seat of an Episcopal bishop. Pop. (1870) 16,507; (1880) 32,016; (1885) 41,934; (1890) 60,278.

Grand Serjeanty (*magna serjeantia*, or *magnum servitium*, 'great service') was one of the most honourable of the ancient feudal tenures. According to Littleton, tenure by grand serjeanty is where a man holds his lands or tenements of our sovereign lord the king by such services as he ought to do in his proper person to the king, as to carry the banner of the king, or his lance, or to lead his army, or to be his marshal, or to carry his sword before him at his coronation, or his carver, or his butler, or to be one of his chamberlains of the receipt of his exchequer, or to do other like services. These honorary services were expressly retained when the military tenures were abolished in 1661. Strathfieldsaye is held by the Duke of Wellington in grand serjeanty, the service required being the presentation to the sovereign of a flag bearing the national colours on each anniversary of the battle of Waterloo. The service by which the Duke of Marlborough holds the manor of Woodstock is the presentation to the sovereign of a French standard on the anniversary of the battle of Blenheim.

In Scotland grand serjeanty was not known as a separate tenure—that is to say, lands held on condition of honorary services rendered to the sovereign were not attended with any privileges other than those attaching to lands held in a similar manner of a subject superior. In that country a tenure by honorary service was known as a Blanch Holding (q.v.).

Grandson. See GRANSON.

Grandville, the pseudonym of JEAN IGNACE ISIDORE GÉRARD, a French caricaturist, who was born at Nancy, 3d September 1803. In 1828 he first attracted attention by a series of humorous sketches entitled *Les Métamorphoses du Jour*, in which men with animals' faces show forth the follies and foibles of human nature. This was followed by several similar series of satirical caricatures of social relations, as *Animaux Parlants*, *Les Gens Proverbes*, *Les Fleurs Animées*, &c. He also practised political caricature with great success. Besides this line of work, he contributed illustrations to splendid editions of the *Fables* of Lafontaine, *Robinson Crusoe*, *Gulliver's Travels*, &c. Grandville died in Paris, 17th March 1847.

Grangemouth, a rising port in Stirlingshire, 3 miles ENE. of Falkirk. Founded in 1777, and erected into a police-burgh in 1872, Grangemouth has extensive quays and warehouses, docks (including a large one opened in 1882), a graving-dock, and shipbuilding yards. The trade of the port has risen very rapidly. In 1840 the shipping entering and clearing it was 31,686 tons annually; in 1876, 840,326; in 1885, 1,457,991; and in 1894, 1,790,281 (one-third in the foreign trade) tons—the port ranking fifth in Scotland. Since 1887 there has been a regular line of passenger steamers between Grangemouth and London, owned by the Carron Iron Company, whose works are within 2 miles of the port. The principal imports are timber, hemp, flax, tallow, deals, iron, and grain; and the exports are manufactured iron, and coal. Grangemouth is noteworthy as having been the place where some of the earliest experiments in Steam-navigation (q.v.) were made. In 1801 the first *Charlotte Dundas* was built there. Pop. (1831) 1155; (1871) 2569; (1881) 4560; (1891) 6354.

Granger, JAMES, born about 1723, was educated at Christ Church, Oxford, and died vicar of Shiplake, in Oxfordshire, in 1776. He published a long popular *Biographical History of England* (1769; 5th ed. 6 vols. 1824), which was 'adapted to a catalogue of engraved British heads,' and insisted much 'on the utility of a collection of engraved portraits.' His advice led to extraordinary zeal in collecting portraits, and 'grangerised copies' became the name for works embellished with engravings gathered from all quarters—frequently secured by the unconscionable mutilation of valuable books of all kinds. A grangerised Bible, in 45 vols. folio, contained 6000 prints, and was valued at 3000 guineas. An edition of Lefevre's Voltaire in 90 vols. contained 12,000 engravings (mostly portraits), and cost the labour of twenty years; it sold in 1856 for £800. A grangerised Clarendon's Rebellion was illustrated by Mr Sutherland at a cost of £10,000. In 1888 a London bookseller had on sale, for £1500, a copy of Boydell's Shakespeare, extended by the insertion of thousands of plates to 36 volumes; the sale price probably did not represent the cost of the grangerising.

Grangers, an American association of agriculturists, founded by a government clerk named Kelly in 1867, under the title of 'patrons of husbandry.' The society had a ritual and four orders for men and women, and aimed at the social improvement and industrial benefit of the farming class. By 1875 there were as many as 30,000 granges organised, but the number was afterwards reduced by dissensions. In 1888 the association was united with the National Farmers' Alliance, founded in the Western States about 1871; and in 1892 the united body, which had attracted a following amongst working men generally, acquired political importance as the People's Party or Populists, and had to be reckoned with at elections. This party advocates the public ownership of the railways and tramways, direct issue of money by government without the intervention of banks, free coinage of silver, and bi-metallism.

Granicus, the ancient name of a small river of Asia Minor, flowing from the northern side of Mount Ida to the Propontis, and now known as the Kodsha-su. On its banks Alexander the Great (q.v.) defeated the Persians.

Granier de Cassagnac. See CASSAGNAC.

Granite (Ital. *granito*, 'gritty;' Lat. *granum*, 'grain'). This well-known rock is a thoroughly crystalline-granular aggregate of quartz, felspar, and mica. The felspar is generally orthoclase (pink or gray), but some plagioclase is often present. The mica may be muscovite or biotite, and other varieties also occur, but the most common perhaps is muscovite. There is no base or matrix in this rock—the several crystals and crystalline granules, confusedly commingled, being bound together by their faces. In crystallising out, the felspar and mica have interfered with each other's development, so that these minerals rarely assume perfect crystalline forms. The quartz still more rarely appears in the form of perfect or even approximately perfect crystals, but occurs as irregular crystalline granules, or seems to be moulded upon and hemmed in between the other minerals. Fluid cavities are generally plentiful in the quartz. As a general rule the component crystals of granite have separated out in the following order: mica, felspar, quartz. Occasionally, however, it is found that the felspar and the quartz have crystallised together, and thus mutually interfered with each other's form. More rarely the formation of the quartz has even preceded

that of the felspar. All varieties of texture are met with among granites, from very fine-grained up to coarsely-crystalline rocks, in which the component crystals may be several inches in diameter. The coarser-grained kinds are called *pegmatite*. In the variety known as *graphic granite* the quartz is crystallised in the orthoclase, forming alternate zigzag-shaped laminæ, which, on a cross-fracture, present the appearance of Hebrew writing. The accessory minerals, such as beryl, topaz, tourmaline, garnet, sphene, &c., are met with chiefly in irregular cavities, and in such cavities very fine crystals of the essential minerals often occur. Scattered through the body of the rock, however, accessory minerals are not uncommon, especially apatite and sphene, and less frequently zircon—these three minerals occurring as inclusions in the essential minerals. The relative proportion of mica, felspar, and quartz varies; in many granites felspar forms more than half of the bulk of the rock—quartz coming next, and mica last. In other granites there is extremely little quartz, while mica is more plentiful. Sometimes the rock is rendered porphyritic by the appearance of large crystals of orthoclase, embedded in a granitoid or finely-crystalline ground-mass. It is generally the felspar which gives the prevalent colour to a granite—the rock being red or gray according as flesh-coloured or white felspar predominates. Very often dark patches and nodules occur in granite. Sometimes these are fragments of foreign rocks more or less altered; at other times they are composed of the same minerals as the granite itself, but in different proportions—mica often predominating. Veins of similar composition are also found ramifying through granite. These and the patches together are supposed to be 'the result of differentiation accompanying the crystallisation of the original magma'—the dark portions being more basic in composition than the rock in which they occur. Most granites are traversed by lighter-coloured veins—some of which are finer grained and others coarser than the rock in which they appear. The origin of these veins is uncertain. They would appear to be of contemporaneous origin with the granite, and to have sometimes formed in rents of the original pasty magma, possibly by segregation of the minerals from the surrounding mass. The fine-grained veins, on the other hand, were probably injected before the granite had become quite consolidated. It seems certain at least that the rock of the veins and the granite itself originally formed portions of one and the same molten mass.

Amongst varieties of granite may be mentioned *hornblendic granite*, in which hornblende is added to the other constituents. When this is the case, mica is only sparingly present. When schorl (black tourmaline) replaces mica, we have *schorlaceous granite*. *Greisen* is a granular aggregate of quartz and mica. *Aplite* is a fine-grained aggregate of quartz and orthoclase, with sometimes a little mica. These three last-mentioned varieties are met with chiefly in veins proceeding from masses of ordinary granite.

Granite usually occurs in great bosses or amorphous masses—and frequently forms the nuclei of mountain-chains. Its petrographical characters and behaviour in the field prove it to be of igneous origin, at all events in the great majority of cases, and to have consolidated at considerable depths in the earth's crust. Hence it belongs to the Plutonic class of igneous rocks. Some writers have held that certain granites are of metamorphic origin, but the appearances which seem to support this view have of recent years received another interpretation. And although, in the present state of our knowledge, it cannot be asserted that no granite is of metamorphic origin, yet it would appear that granites of demonstrably metamorphic origin have not yet been discovered. Those which are supposed to be of such origin are intimately associated with crystalline schists, which themselves are believed to be the result of metamorphic changes. At one time granite was looked upon as the oldest of primitive rocks, but it is now known to be of various ages. Its presence at the surface is due of course to denudation, which has removed the great masses of rock that originally covered it.

The more durable kinds of granite are largely used as building materials in bridges and engineering-works, and also in public buildings and dwellings. The difficulty of working it makes it expensive, but this is counterbalanced by its great durability. It cannot be cut, like the majority of building-stones, with saws, but is worked first with large hammers, and then with pointed chisels. The success with which the Egyptians operated upon this refractory stone is very extraordinary. They worked and polished it in a way that we cannot excel, if, indeed, we can come up to it, with all the appliances of modern science; and not content with polishing, they covered some of the blocks with the most delicate and sharply-cut hieroglyphics!

The granites best known in the British Islands for ornamental purposes are the gray Aberdeen granite and the reddish-coloured Peterhead granite. Of this last-mentioned variety handsome polished columns for public halls have been constructed. On the Continent granite has been quarried for similar purposes in several countries: as near Baveno in Italy, and in the islands of Sardinia and Elba; in Normandy and Brittany; in southern Sweden, Finland, the Tyrol, Switzerland, &c. In North America granites are worked at a number of places, as in Maine, New Hampshire, Massachusetts, Connecticut, New York, Michigan, and California, and at various places in the Canadian province of Quebec. The rock would probably be more abundantly used than it is, were it not for the fact that in many cases it occurs at elevations and in districts more or less difficult of access.

The soil produced by the weathering of granitic rocks should be fertile, as their component ingredients yield the necessary elements. But in hilly districts, where granite is chiefly developed, the fine clay which results from the decomposition of the felspar is washed away, so that only the quartz sand is left on the slopes—forming a thin, ungrateful soil. In the hollows and flats whither the clay is transported we find generally a cold, stiff, and wet subsoil, which is only worked with difficulty. In low-lying granitic tracts, especially under genial climatic conditions, the soil which results from the weathering of granite is sometimes very fertile. See Geo. F. Harris, *Granite and the Granite Industries* (1888).

Gran Sasso d'Italia ('Great Rock of Italy'), also called MONTE CORNO, from the resemblance to a horn which it presents on the east, is situated on the borders of the Abruzzi, between Teramo and Aquila. It is the highest summit of the Apennines, having an elevation of 9574 feet.

Granson, or GRANDSON, an ancient town in Switzerland, on the Lake of Neuchâtel, 21 miles SW. of Neuchâtel; pop. 1762. Here in 1476 the Swiss defeated Charles the Bold (q.v.).

Grant, in English law, the conveyance of property by deed. Movables are granted when they are comprised in a bill of sale or deed of gift. Incorporeal hereditaments, and interests in land not involving actual possession, were also said to lie in grant; but a freehold in possession could

only be conveyed by livery of seisin—i.e. by solemn delivery of possession. The Real Property Act of 1845 enacted that the immediate freehold might be conveyed by deed of grant. It is no longer necessary to use the word 'grant;' other words, such as 'convey,' will have the same effect. A grant of the reversion of land under lease was formerly completed by the lessee attorning (becoming) tenant to the grantee; but the necessity for attornment is now abolished. In the United States generally livery of seisin is dispensed with, and the term 'grant' applies to all transfers of real property.

Grant, FAMILY OF. Among various conflicting theories as to the origin of this family, the most probable is, as the name seems to indicate, that it is of Norman extraction, and that it was introduced into Britain at the Conquest. Occasionally it appears in parts of England; but by the middle of the 13th century it had established itself in the north of Scotland—Laurence le Grant holding the responsible office of sheriff of Inverness in 1263. He and his descendants acquired large territories in the great Caledonian Glen, and also in Strathspey, Freuchie, now Castle Grant, near Grantown, becoming their principal barony and residence. The sixth laird of Freuchie was knighted by King James VI., and his grandson had his lands erected into the regality of Grant—whence their designation since. Sir Ludovick Grant, fourth laird of Grant, married as his second wife, Lady Margaret Ogilvie, daughter of James, fifth Earl of Findlater and Seafield, and, through this marriage, their grandson succeeded in 1811 to the earldom of Seafield, assuming the surname of Ogilvie in addition to that of Grant. Through another marriage, a younger brother of the fourth laird of Grant succeeded to the estates of the Colquhouns of Luss, and, assuming the surname of Colquhoun, became the ancestor of the present family of that name. *The Chiefs of Grant* (3 vols. 4to, 1883), prepared by Sir William Fraser, K.C.B., for the family, presents a history of its descent, and also shows the dispersion of its numerous cadet branches, many members of which have become distinguished in various spheres of life.

Grant, SIR ALEXANDER, of Dalvey, was born at New York in 1826, and represented one of the oldest branches of the Clan Grant. Educated at Harrow and Balliol College, Oxford, he graduated B.A. in 1848, and was elected to an Oriel fellowship. Here he edited the *Ethics of Aristotle* (1857), with English notes, a work which still maintains a reputation by its suggestive preliminary essays. He succeeded as baronet in 1856, was appointed inspector of schools at Madras in 1858, and became professor of History in Elphinstone College there; then its principal; and afterwards vice-chancellor of Elgin College, Bombay, in all which positions he did much to promote the interests of education in India. On the death of Sir David Brewster he was in 1868 chosen as principal of the university of Edinburgh, an office which he enjoyed for sixteen years, during which took place the inauguration of the new medical school, and the tercentenary celebration of the university. His *Story of the University of Edinburgh* (1884) was published in connection with the latter event. Earlier works were *Aristotle* and *Xenophon*, in Blackwood's 'Ancient Classics;' and *Essays Studies* (1870), a volume of essays written by various scholars. The universities of Edinburgh and Glasgow conferred upon him the degree of LL.D., and Oxford that of D.C.L. He married, in 1859, Susan, daughter of Professor Ferrier of St Andrews, and died suddenly on 1st December 1884.

Grant, MRS ANNE, a miscellaneous writer, whose works were among the first to draw public attention to the romantic scenery and peculiar manners of the Scottish Highlands, was born in Glasgow, 21st February 1755. She was the daughter of a British officer, Duncan M'Vicar, who became barrack-master of Fort-Augustus. She married in 1779 the Rev. James Grant, formerly chaplain of the fort, minister of Laggan. Left a widow in destitute circumstances in 1801, Mrs Grant published by subscription a volume of *Poems* (1803), which were well received; *Letters from the Mountains* (1806), a highly popular work; *Memoirs of an American Lady* (1808); *Essays on the Superstitions of the Highlanders of Scotland* (1811), &c. In 1825 she received a pension of £100 a year, and by legacy from Sir William Grant, Master of the Rolls, she enjoyed a similar annuity. She died on 7th November 1838. A memoir of her life, and a selection from her correspondence, forming a continuation of her *Letters from the Mountains*, were edited by her son, J. P. Grant, in 1844.

Grant, CHARLES, LORD GLENELG, son of Charles Grant, sometime M.P. for Inverness-shire, and a distinguished director of the East India Company, was born at Kidderpur, near Calcutta, in 1778. He was of the Grants of Sheuglie, cadets of the Grants of Grant. He was educated at Magdalene College, Cambridge, where he took his degree of M.A. in 1804. In 1805 he published a poem on the *Restoration of Learning in the East*, which had won the university prize awarded by Dr Claudius Buchanan. He was called to the bar in 1807, but never practised. In 1811 he was elected M.P. for the Inverness district of burghs; and afterwards, succeeding his father in the county representation, continued in the House of Commons till 1835, when he was raised to the peerage. Grant held for five years the office of a Lord of the Treasury, and in 1819 was appointed Secretary for Ireland, which he continued to be for about two years. As Irish Secretary he endeavoured to suppress the Orange demonstrations, to secure the impartial administration of justice, and to devise a system of national education adapted for Catholics as well as Protestants. From 1823 to 1827 Grant was Vice-president of the Board of Trade; from 1830 to 1834 President of the Board of Control; and from 1834 to 1839 Secretary of State for the Colonies. After this he withdrew in a great measure from public affairs, but supported the Liberal party by his vote. He died at Cannes, in France, in 1866, unmarried. Lord Brougham pronounced Grant to be 'the purest statesman he had ever known.' He was an eloquent speaker, though, partly from diffidence and partly from indolence, he spoke but seldom. Some of his despatches as colonial secretary, on the rights of the natives in the colonies, on repressing idolatry, and abolishing slavery throughout the British possessions in South Africa, are models of elevated and just thought, and of fine impressive English.

Grant, SIR FRANCIS, fourth son of Francis Grant of Kilgraston, Perthshire, was born in Edinburgh on 18th January 1803. He was educated at Harrow and the university of Edinburgh for the Scottish bar, but abandoned that profession to follow his natural genius for painting. A noble portrait by Velasquez is said to have exercised an especial influence over the young painter's future career. His first picture was exhibited in 1834, when he at once took rank among the best portrait-painters of the day, and was regarded as a worthy successor of Lawrence. His most famous works are those in which he has combined the likenesses of distinguished characters with scenes of English sport. The 'Meet of H.M. Staghounds,'

painted in 1837 for Lord Chesterfield, and containing no less than forty-six portraits; the 'Melton Hunt,' executed for the Duke of Wellington; and the 'Cottesmore,' for Sir R. Sutton, are the best known in this class. Among his other paintings may be mentioned the equestrian portraits of the Queen and Prince Consort for Christ's Hospital; the picture of the beautiful Marchioness of Waterford; and those of Lords Palmerston, Russell, Gough, Macaulay, Hardinge, &c. In 1842 Grant was elected Associate, and in 1851 Academician. In 1866 he became President of the Royal Academy and was knighted. In 1870 Oxford conferred upon him the degree of D.C.L. He died on 5th October 1878.

Grant, JAMES, of Corrimony, in Inverness-shire, a cadet of the Grants of Grant, born in 1743, died in 1835, was author of *Essays on the Origin of Society* (1785) and *Thoughts on the Origin and Descent of the Gael* (1814).

Grant, JAMES, military novelist, was born in Edinburgh, 1st August 1822, and in 1832 sailed with his father, an army officer, for Newfoundland. Home again, in 1839 he was gazetted to an ensigncy in the 62d Foot, but within a few years resigned his commission, and turned to literature. Having already contributed copiously to the *United Service Magazine* and the *Dublin University Magazine*, he in 1846 published his first book, *The Romance of War*. Since then he supplied his legion of readers with a long and close series of novels and histories, illustrative mainly of war, and, more particularly the achievements of Scottish arms abroad. Among his many works may be mentioned *Adventures of an Aide-de-Camp; Adventures of Rob Roy; Frank Hilton, or the Queen's Own; Bothwell, or the Dark Days of Queen Mary; The Yellow Frigate; Harry Ogilvie;* and *Old and New Edinburgh*. Most of his works have reappeared in German and Danish, as also a few in French. In 1875 Cardinal Manning received him into the Roman communion. He died in London, 5th May 1887.

Grant, COLONEL JAMES AUGUSTUS, C.B., F.R.S., was a son of the Rev. James Grant of Nairn, where he was born in 1827. Having been educated at the grammar-school and Marischal College, Aberdeen, he was in 1846 appointed to the Indian army. His services at the battle of Gujerat, under Lord Gough, gained him the medal and two clasps, and his further services in India, in the course of which he was wounded, were honoured by the Mutiny medal and clasp for relief of Lucknow. With Captain Speke he explored (1860–63) the sources of the Nile. He also received the medal for services in the Abyssinian Expedition of 1868. Among his publications are *A Walk Across Africa;* 'Summary of the Speke and Grant Expedition,' in the *Jour. Roy. Geog. Soc.* (1872); *Botany of the Speke and Grant Expedition;* and *Khartoum as I saw It in 1863*. A gold medallist of the Royal Geographical Society, he died 10th February 1892.

Grant, SIR JAMES HOPE, general, brother to Sir Francis, was born at Kilgraston, Perthshire, 22d July 1808. He first saw service in the Chinese war of 1842, and next distinguished himself at Sobraon, Chillianwalla, and Gujerat in the two Sikh wars. During the operations of the Indian Mutiny Grant, who had risen to the rank of lieutenant-colonel, took a leading part, assisting in the recapture of Delhi (20th September), in the relief of Cawnpore, and in the retaking of Lucknow, and he commanded the force which effected the final pacification of India. In 1859 he conducted the war against China, defeating the enemy three times under the walls of Pekin, assaulting the Taku forts, and finally capturing the capital of the empire, for which work he was created G.C.B. After commanding the army of Madras from 1861 to 1865, he returned to England, and was made general in 1872. He died in London, 7th March 1875. From his journals appeared *Incidents in the Sepoy War of 1857–58* (1883) and *Incidents in the China War of 1860* (1875), edited by Col. H. Knollys, who also published a Life of him (2 vols. 1894).

Grant, MRS, of Carron, author of the popular song, 'Roy's Wife of Aldivalloch,' was born near Aberlour, Banffshire, in 1745. She was twice married—first to her cousin, Captain James Grant of Carron, in Strathspey; and afterwards to Dr Murray, a physician in Bath. She died at Bath in 1814.

Grant, ULYSSES SIMPSON, eighteenth president of the United States, was born at Point Pleasant, Clermont county, Ohio, April 27, 1822. He was of Scottish ancestry, but his family had been American in all its branches for eight generations. Ulysses was the eldest of six children born to Jesse R. Grant and his wife Hannah Simpson, and assisted his father on the farm in summer, attending the village school during the winter. In the spring of 1839 he was appointed to a cadetship in the United States Military Academy, and graduated in 1843. He was commissioned brevet second-lieutenant, and assigned to duty at Jefferson Barracks, Missouri. In May 1844 he accompanied his regiment, the Fourth Infantry, to Louisiana, and in September 1845 he was commissioned second-lieutenant, and joined the army of occupation under General Zachary Taylor. Grant participated in the battles of Palo Alto and Resaca de la Palma, and was also present at the capture of Monterey. Later the Fourth Infantry embarked for Vera Cruz, to join the army of General Winfield Scott, and Grant took part in all the battles of Scott's successful campaign and in the final capture of the city of Mexico. In the summer of 1848 his regiment returned to the United States, when he obtained leave of absence, and in August of that year was married to Julia B. Dent, of St Louis, by whom he had three sons and a daughter, the eldest of whom, Colonel Frederick D. Grant, was in April 1889 appointed American Minister to Austria. Lieutenant Grant served at various posts; was in 1853 appointed to a captaincy; and in the following year resigned his commission, and settled on a farm near St Louis, Missouri.

Copyright 1890 in U.S. by J. B. Lippincott Company.

When the war began in April 1861 Grant was residing in Galena, Illinois; he immediately offered his services to the government, and in June he was appointed colonel of the 21st Regiment of Illinois Infantry, with which he was sent to Missouri. In August he was advanced to brigadier-general of volunteers, and assigned to the command of a district, and in November he fought the battle of Belmont. In February 1862 he captured Fort Henry, and ten days later Fort Donelson, with 14,623 prisoners, for which victories he was made major-general of volunteers. In April Grant fought a two days' battle at Shiloh, amongst the severest of the war, in which General A. S. Johnston, commanding the Confederate army, was killed. After various unsuccessful movements against Vicksburg, which commenced in the November of 1862, Grant crossed the Mississippi, April 30, 1863, defeated the enemy at Port Gibson and at Champion Hill, and drove them behind their entrenchments at Vicksburg, to which place he laid siege. After many assaults, the stronghold surrendered conditionally on July 4, 1863, with 31,600 prisoners and 172 cannon, and the Mississippi was opened from its source to its mouth. In October Grant was ordered to Chattanooga,

where he fought a battle, capturing the enemy's entire line, and driving him out of Tennessee. In March 1864 Grant, having previously been made a major-general in the regular army for his victory at Vicksburg, was promoted to the grade of lieutenant-general, and assigned to the command of all the armies of the United States, with his headquarters with the army of the Potomac. His plan of campaign was to concentrate all the national forces into several distinct armies, which should operate simultaneously against the enemy, Sherman moving toward Atlanta, while Grant himself accompanied the army of the Potomac against Richmond. During the night of May 4 the latter crossed the Rapidan, encountered General R. E. Lee in the Wilderness, and fought a desperate three days' battle, one of the fiercest of modern times. Grant moved forward on the 7th, and fought again at Spottsylvania Courthouse on the 10th, and still again on the 12th, on which occasion he captured an entire division of the Confederate army. The smoke of battle hung over the mighty hosts for six days, while the North remained in a state of suspense bordering upon agony; but on the 11th Grant wrote to Washington, 'I propose to fight it out on this line, if it takes all summer.' Thus, fighting and flanking, ever pursuing the offensive, and daily drawing nearer to Richmond, he at length drove the enemy within the defences of that city, and there held him in a vice, while he left to his lieutenants —Sherman, Sheridan, and Thomas—a harvest of laurels by active movements and successful battles. On March 29, 1865, there began a week's hard fighting, at the close of which Lee surrendered his entire army at Appomattox Courthouse, April 9, receiving from his victor most generous terms. The fall of Richmond substantially ended the war, and Grant returned to Washington to prepare his report of the operations of the armies of the United States from the date of his appointment to command the same, and to muster out nearly a million of troops that the country no longer required.

In July 1866 Grant was advanced to the grade of full general, and in May 1868 he was nominated for the presidency by the Republican convention, and in the following November was elected. Out of the 294 electoral votes Grant received 214, and Horatio Seymour, the Democratic candidate, 80. He was again elected to the presidency in November 1872, thus filling the office of chief-magistrate for eight years. Among the most important events of his administration were the adoption in 1869 of the fifteenth amendment to the constitution, which guaranteed the right of suffrage without regard to race, colour, or previous condition of servitude; and the peaceful settlement of the 'Alabama Claims' (see ALABAMA). After retiring from the presidency, General Grant spent two years in foreign travel, receiving unusual attentions from the rulers of the various countries which he visited in his tour round the world. In June 1880 his name was again presented to a Republican convention, but, chiefly owing to a traditional sentiment against a third term of the presidency, the nomination was given to James A. Garfield. In 1881 Grant purchased a house in New York, where he afterwards passed his winters, while his summers were spent in his seaside cottage at Long Branch, New Jersey. Finding himself unable with his income to properly maintain his family, he became a partner in a banking-house in which one of his sons and others were interested, bearing the name of Grant and Ward, and invested all his available capital in the business, but taking no part in the affairs of the firm, which were left almost entirely in the hands of the junior partner. In May 1884 the house, without warning, suspended, and it was then discovered that two of the partners had robbed the general and his family of all they possessed. Until this time Grant had refused all solicitations to write the history of his military career; but now, finding himself bankrupt, and with the hope of providing for his family, he began the preparation of his personal memoirs. The contract with his publishers was made February 27, 1885, and the work appeared about a year later. In the summer of 1884 he complained of a soreness in his throat, and an examination detected the presence of cancer at the root of the tongue. The sympathies of the nation were now aroused, and on March 4, 1885, congress passed a bill creating him a general on the retired list, thus restoring him to his former rank in the army, which he had lost on accepting the presidency. It may be doubted if since the world began any book has been written under similar conditions; the dying soldier, suffering constant and at times the severest agony, yet struggled on successfully, completing his literary labours only four days before his death at Mount McGregor, near Saratoga, New York, 23d July 1885. His remains were removed to New York, and on August 8 were interred with great pomp in Riverside Park, overlooking the Hudson. Many lives of Grant have been written, the most valuable of which is his own (2 vols. 1885-86), a work that brought his widow no less than $500,000.

Grantham, a market-town of Lincolnshire, on the left bank of the Witham, 25 miles SSW. of Lincoln, and 105 NNW. of London. It lies on the ancient Ermine Street, and is an important junction on the Great Northern Railway; whilst a canal (1793), 30 miles long, connects it with the Trent near Nottingham. High over the red-tiled brick houses soars the noble gray spire (278 feet high) of St Wolfran's Church, which, in style mainly Early English of the 13th century, has been finely restored by the late Sir G. G. Scott since 1865. An Eleanor cross was demolished in 1645, and a castle has left no trace; but the quaint Angel Inn is still standing, in which Richard III. signed Buckingham's death-warrant. Of King John, too, Grantham has memories, and of Oliver Cromwell, who here on 13th May 1643 won his first success; but the town's greatest glory is Sir Isaac Newton, who during 1655–56 idled, fought, and rose to be head-boy in its grammar-school. A bronze statue of him by Theed was erected in 1858. The said school was founded by Bishop Fox in 1528, re-endowed by Edward VI. in 1553, and reconstituted in 1876. The manufacture of agricultural implements, malting, and brick-making are the chief industries. Grantham was incorporated by Edward IV. in 1463, and from then till 1885 returned two members to parliament a number reduced now to one. The borough boundary was largely extended in 1879. Pop. (1851) 10,873; (1871) 13,250; (1881) 17,345, of whom 16,886 were within the municipal borough; (1891) 17,170. See the local histories of Turnor (1806), Marrat (1816), and Street (1857).

Grant Land, a North Polar region, lying north of Grinnell Land, between 81° and 83° N. lat., discovered by Hayes, Hall, and Nares in 1875, and partly explored by Nares, who wintered on its coasts, in the most northerly latitude (82° 27′) in which the winter has been passed by any ship.

Granton, a harbour on the Firth of Forth, 3 miles NNW. of Edinburgh. It was constructed by the Duke of Buccleuch in 1835–45 at a cost of nearly a quarter of a million.

Grantown, a village of Elginshire, ¾ mile from the Spey's left bank, and 142 miles by rail N. by W. of Edinburgh. Founded in 1776, and created a police-burgh in 1890, it is a popular holiday resort. Pop. 1423.

Granulations, the materials of new texture as first formed in a wound or on an ulcerated surface. See INFLAMMATION, CICATRISATION, WOUNDS, ULCER.

Granulite, or LEPTYNITE, a schistose but sometimes massive aggregate of quartz and orthoclase with garnets. The garnets are disseminated irregularly, and are not infrequently accompanied by Kyanite (q.v.). This rock is classed with the crystalline schists.

Granvelle, ANTOINE PERRENOT DE, Cardinal and statesman (whose name out of France was subsequently spelt Granvella), was born in 1517 at Ornans in Burgundy. He studied law at Padua, and theology at Louvain. A canon for a short time at Besançon, he was in 1540 appointed Bishop of Arras. His father now chancellor of the empire under Charles V., he was entrusted with many diplomatic missions, which he discharged with marked ability. Succeeding his father in the chancellorship in 1550, he accompanied Charles V. in the flight from Innsbruck, and framed the treaty of Passau, 1552. On the abdication of Charles in 1555 he transferred his services to Philip II. In 1559 he was appointed prime-minister to Margaret of Parma in the Netherlands. In 1560 he was created Archbishop of Malines, and next year was made cardinal. Such, however, was the hostility which his policy of repression provoked in the Low Countries that at the king's advice he retired in 1564 to Franche Comté. After six years of comparative quiet he in 1570 represented Spain at Rome in drawing up a treaty of alliance with Venice and the papal see against the Turks. For five years (1570–75) he successfully held the office of viceroy of Naples. He died at Madrid in 1586.

Granville, a fortified seaport in the French department of La Manche, is situated on a rocky promontory on the English Channel, 23 miles NE. of St Malo. The 15th-century church and a hydrographic college are the principal institutions. Chief industries, fishing (oysters and cod), shipbuilding, manufacture of brandy, chemicals, ironware, and tanning; chief exports, fish and buildingstone; chief imports, salt, manure, corn, and flour. Pop. (1886) 11,513. The town has been captured by the French (1450) and the English (1695), and unsuccessfully besieged by the Vendéans (1793) and the English (1803).

Granville, EARL. See CARTERET.

Granville, GEORGE LEVESON-GOWER, second EARL, statesman, was born May 11, 1815, being the eldest son of the first earl. He was educated at Eton and Oxford, and entered parliament in 1836 as member for Morpeth, exchanging that seat for Lichfield in 1840. His long and intimate acquaintance with foreign politics began at this time, and he filled for a brief period the post of Under-secretary for Foreign Affairs. He was a consistent Liberal and a free-trader. He succeeded to the peerage in 1846, and five years later entered the cabinet of Lord John Russell, holding the seals of the Foreign Office. From that time forward he held office in every Liberal ministry. He became President of the Council in 1853, and leader of the House of Lords in 1855. He laboured arduously in connection with the great exhibitions of 1851 and 1862. Lord Granville was charged to form a ministry in 1859; but having failed to do so, he joined Lord Palmerston's second administration. He retired with Earl Russell in 1866, having the preceding year been made Lord Warden of the Cinque Ports. In December 1868 he was appointed Colonial Secretary in Mr Gladstone's first ministry, and on the death of Lord Clarendon in 1870 became Secretary for Foreign Affairs. He arranged the treaty between England, France, and Prussia guaranteeing the independence of Belgium; and confirmed with Prince Gortschakoff the agreement that Afghanistan should form an intermediary zone between England and Russia. His lordship went out of office in 1874, took the temporary leadership of the Liberal party on Mr Gladstone's retirement in 1875, and for six years led the opposition in the House of Lords with ability and spirit. In 1880 he again became Foreign Secretary under Mr Gladstone, and displayed considerable diplomatic skill in matters relating to the Berlin Treaty, the occupation of Tunis, and the revolt of Arabi Pasha in Egypt. He issued a circular note to the powers on Egyptian reforms, and in 1884 convened a conference on Egyptian finance, which proved abortive owing to the hostile attitude of France. Troubles in the Soudan, difficulties with Germany in consequence of Prince Bismarck's colonial schemes, differences with France, and the threatened rupture with Russia over the demarcation of the Afghan boundary caused Lord Granville much solicitude during the closing years of Mr Gladstone's second administration. He retired with his chief in 1885, but returned once more to office as Colonial Secretary in 1886, resigning again with his colleagues in August of the latter year. A steady supporter of Mr Gladstone's Home-rule policy, he died 31st March 1891.

Grape. See VINE.

Grape-hyacinth (*Muscári*), a genus of bulbous-rooted plants, of the natural order Liliaceæ, nearly allied to the hyacinths, but differing in the globose or subcylindrical perianth, contracted at the mouth, and 6-toothed. The species are natives chiefly of the countries near the Mediterranean, and the warmer temperate parts of Asia. Most of them are now frequent in our flower-borders. *M. moschatum* has a smell of musk. *M. racemosum*, popularly named Starch Hyacinth, is a somewhat doubtful native of the south-eastern counties—having, it is believed, escaped from gardens—of England. The flowers of the grape-hyacinths are mostly normally blue, but there are pure white varieties of some species.

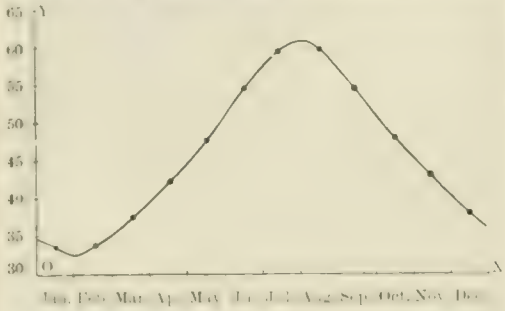
Grape-shot, called also *tier-shot*, consists of small iron balls piled round an iron pin, holding together a series of parallel iron plates of the same diameter as the gun from which they are to be fired, between which are the shot, kept in their places by holes in the plates. On being discharged they spread over a wide area. In another pattern called *quilted* grape the shot are held together on the central pin by canvas instead of iron plates. Both have now almost ceased to be used, their place being taken by *case-shot*, sometimes called *canister*.

Grape-shot.

Grape-sugar. See SUGAR.

Graphic Methods. Under Composition and Resolution of Forces it has been noticed that the point of application, the direction, and the intensity of any force may be represented by the end, direction, and length of a straight line. Similarly, any other physical quantity, such as temperature, atmospheric pressure, or barometric height, electric potential, &c., may be represented by straight lines. Such modes of showing the value of a quantity are called graphic methods; they are largely employed in physical investigations as aids to calculation, and for the purpose of exhibiting the nature of the law according to which some phenomena vary. The principal use of this method is to show the mutual variations of two quantities. This we will illustrate by a particular example.

Suppose a table is drawn up, in one column of which are the months of the year, and in the other the corresponding average temperatures of the air, at some particular place, during these months (the average temperature for each month being the mean of the daily temperatures). Let two lines, OX and OY, be drawn from O, one horizontally, the other vertically; let the successive months of the year be represented on any convenient scale along OX, and let temperature be measured along OY, also on a convenient scale. Corresponding to each month in the year there will be a length along OX, and to each temperature there will correspond a point on OY. At the middle point corresponding to each month draw perpendicular to OX a line representing the temperature on the scale of OY. A series of lines will thus be obtained,



through the upper ends of which there may be drawn, freehand, a smooth curve. The points on the curve in the figure represent the upper ends of these lines. A general glance at such a curve will reveal certain features regarding the temperature of the whole year; at what dates maxima and minima occurred; when the temperature rose or fell quickest, and so on. Such a curve, representing the gradual change of daily temperature, may be produced automatically by photographic representation: a sheet of sensitised paper passes uniformly, by means of clockwork, behind the thermometer stem, in front of which is placed a source of light; the paper above the mercury column is blackened, that below being left unaffected; the curve separating the black and white portions represents the temperature at different times. The same principle is used in the thermograph, barograph, and tide-gauge recording machine.

Instead of time and temperature any other two variable quantities may be taken. When the curve obtained by such graphical methods has some regular geometrical features the mathematical law of the phenomenon may be found; and many qualitative and quantitative results in physics are obtained in this way. It must be remembered that such graphical representations do no more than embody the results of observation or experiment, and cannot be made more accurate than the data themselves.

The graphic method is so largely employed in physical science, and also in statistics, that only a few instances of its application may be given. Watt's Indicator Diagram shows the amount of work done in a complete (double) stroke of the piston; it acts on the principle that the force applied multiplied by the distance through which it acts is a measure of the work done. Pressure and volume are therefore the variables here involved. The temperature of a body at different times may be given by a curve, from which may be found the rate of cooling; a curve may also represent the temperature at different points of a body, and from it may be deduced, if its thermal conductivity be known, the flux of heat across any section of it. The thermo-electric diagram (see Tait's *Heat*) is also a valuable application of the method. Andrew's diagram of the volume of carbonic acid gas under varying pressure may be mentioned as another (see Andrew's *Collected Scientific Papers*, Lond., Macmillan, 1889). The method has also many applications in electricity—e.g. the 'arrival' curve in a submarine cable; and in sound, where acoustic vibrations, beats, and harmonics may be graphically represented.

Graphic Statics. When forces simultaneously act on a particle which remains at rest they are in equilibrium, and, if there be three of them, lines drawn so as to represent the respective forces in magnitude and direction may be so arranged as together to form the well-known Triangle of Forces. Problems in which trigonometrical methods of finding the magnitude and direction of the third side of such a triangle (the resultant) are applied, when those of the other two (the components) are known, or of resolving any given force in any given direction into two 'components' in any two assigned directions, are of common occurrence in text-books. For practical purposes, however, it is very useful actually to draw to scale the triangle of forces appropriate to the data of any particular case; two sides being thus drawn to scale, the third side can be laid down by simply joining two points, and then the line so drawn can be measured with respect to its length and its direction. Similarly the resultant of a number of simultaneous forces can be usefully ascertained by drawing the corresponding Polygon of Forces, and ascertaining the lie and the length of the missing side. The utility of this graphic method is, however, most fully seen in the recent extensions of this method to engineering work. The subject of Graphic Statics is a large one, and we can do little more here than refer the reader to Cotterill's *Applied Mechanics*, which gives, incidentally, full references to the literature of the subject; but in order to give an idea of the nature of the method one illustration may here be supplied. Suppose a bridge-girder (weightless) made up of two N girders in ten divisions (fig. 1), the diagonals being all so arranged as to be in tension; it is 100 feet long, and a load of 100 tons is distributed over it so as to rest uniformly upon the lower booms. Find the stress in each bar. First draw the girder to scale, and mark the bars as in fig. 2: The lower boom of each division may, so far as the

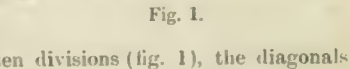


Fig. 1.

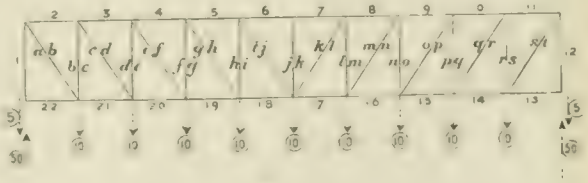

Fig. 2.

girder at large is concerned, be considered as having its proportion of the uniform load (10 tons) arranged in 5-ton loads at its two ends; hence at the angle between 1 and 22, and also at 12–13, there are imaginary loads of 5 tons; at *bc*, *de*, *fg*, &c., imagine 10-ton loads. The supporting piers each exert an upward pressure of 50 tons. There is equilibrium, and this equilibrium may be traced out

at every angle of the structure. At the angles 1–22 and 12–13 the upward pressure of the piers is partly neutralised by the local weight of 5 tons; the vertical bars 1 and 12 have each an upward thrust of 45 tons, which carries the girder; but at these angles there are no horizontal components

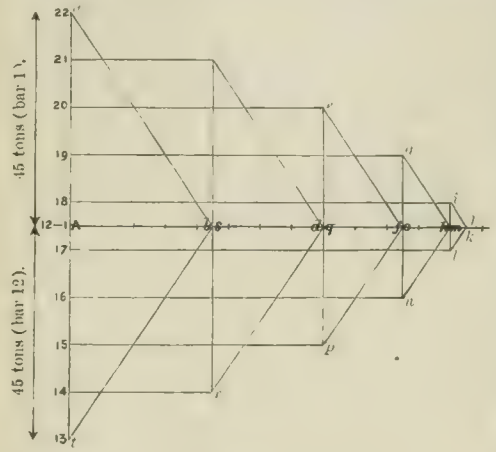

Fig. 3.

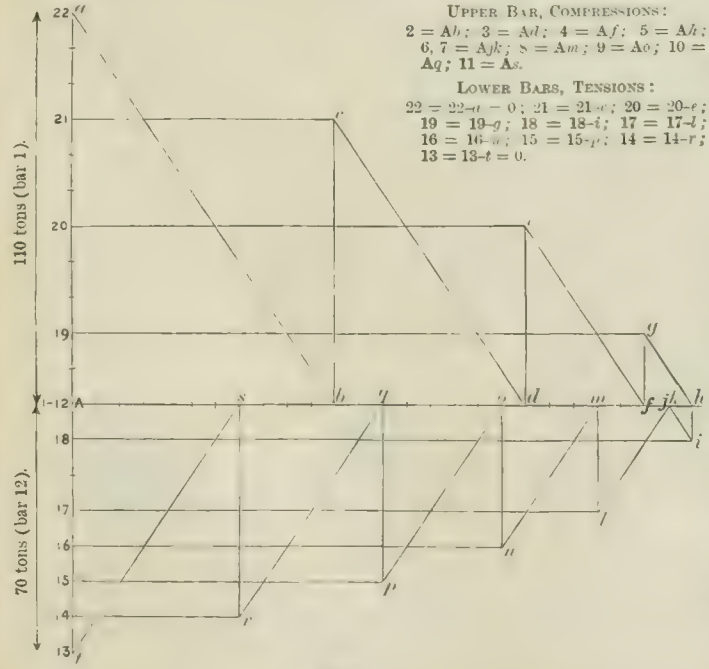
along 22 and 13, which, therefore, have no thrust along them, and are neither compressed nor in tension. If a vertical line *a t* (fig. 3) be drawn, each division in which represents 10 tons, the distribution of load may be set out by taking a starting-point, A: then there is in the girder, from 1 round to 12, no load introduced; between 12 and 13 there is introduced what is equivalent to an upward force of 45 tons in bar 12, and the representation of this is



Upper Bar, Compressions:
2 = Ab; 3 = Ad; 4 = Af; 5 = Ah; 6, 7 = Ajk; 8 = Am; 9 = Ao; 10 = Aq; 11 = As.
Lower Bars, Tensions:
22 = 22–a = 0; 21 = 21–c; 20 = 20–e; 19 = 19–g; 18 = 18–i; 17 = 17–l; 16 = 16–n; 15 = 15–p; 14 = 14–r; 13 = 13–t = 0.
110 tons (bar 1).
70 tons (bar 12).

Fig. 4.

prepared for by setting off 4½ divisions *downwards*: then between 13 and 14 there is a downward load of 10 tons, and the diagram sets off one division upwards, to 14; so for each of the junctions as far as 21–22, and then at 22–1 there is an upward 45 tons in bar 1, the setting-off for which brings us back to A. At the junction 1–2 we have three bars in equilibrium; these are 1, 2, and *ab*; the stress in 1 is 45 tons; drawing a triangle, A*ab* (fig. 3), in which the sides are parallel to 1, 2, and *ab*, we find the relative compressions in 1 and 2, and tension in *ab*. At the next junction, *ab–bc* (fig. 2), we have four balanced forces, the tensions in 21 and *ab*, compression in *bc*, and a load of 10 tons. From the extremities of *ab* (fig. 3) draw 22–21 representing the 10-ton load acting downwards, and *bc* a line parallel to *bc* in fig. 2; join 21 and the line *bc* by a line parallel to the rod 21, the tension in which is now represented by the line 21–*c*, while *bc* (fig. 3) represents the compression in *bc* (fig. 2). Next consider the junction 2–3; four bars, 2, *bc*, *cd*, and 3; 2 we know (= A*b*, fig. 3), and also *bc*; we draw a line *cd*, and a line parallel to 3 which, in order to complete the polygon, can only start from A; A*d* and *cd* represent compression and tension in 3 and *cd* respectively. At the next junction, 21–20, we have 21 (= 21–*c*), *cd* (= *cd*), *de* (unknown), 20 (unknown), and a 10-ton load; the polygon is completed by 20*e* and *de* drawn from the ends of the broken line *dc* 21–20. Step by step, by mere drawing of intersecting lines, and by a process which, once the foundation has been laid by setting out the distribution of loads, is far more expeditious and simple than the explanation of it can at first enable it to appear, fig. 3, the measurable diagram of the girder-bar stresses, is evolved, and it is seen that as we near the centre the tensions on the diagonals diminish, that the vertical bar *jk* is neither under compression nor tension, and that the bars 6 and 7 are under the maximum compression (= A–*jk*), and the bars 18 and 17 under the maximum tension (18–*i*, 17–*l*). It will be seen that the diagram is symmetrical; but, if we take the case of a non-uniformly distributed load, the diagram becomes unsymmetrical. Suppose another 100 tons to be laid uniformly upon the lower booms of the left-hand half of the girder: now the piers respectively support 125 and 75 tons; the stresses in bars 1 and 12 are 110 and 70 tons; the diagram, built up on the same principles as in the preceding case, and drawn to a scale reduced to three-fourths, takes the form shown in fig. 4.

See R. H. Smith, *Graphics: or the Art of Calculation by Drawing Lines* (1889).

Graphis (Gr. *graphō*, 'I write'), a genus of lichens, which gives its name to a tribe, Graphideæ, remarkable for the resemblance which the fructification (*apothecia*, or *shields*) assumes to the forms of the letters of oriental alphabets. *G. scripta* is common in northern Europe, but of the twenty species the great majority are tropical. Some are said to assist in the identification of cinchona barks of particular species, growing on certain kinds and not on others.

Graphite. See Black Lead.

Graphophone. See Phonograph.

Graphotype was one of the many processes intended to supersede wood-engraving. The design was sketched with silicate on a prepared chalk

surface, and the chalk brushed away from between the lines. From the chalk an electrotype could be taken. It had a temporary partial success, but has been in turn completely superseded by the zincotype and other processes. See ILLUSTRATION.

Grapple-plant (*Uncaria procumbens*), a procumbent plant of the same genus with the Gambir (q.v.), a native of South Africa. The seed-vessel has many hooked thorns, and clings most tenaciously to any animal—a provision for the distribution of the seed. When it lays hold of the mouth of an ox, Livingstone says, the animal stands and roars with pain and a sense of helplessness.

Graptolites, a group of fossil hydrozoa, apparently related to the recent Sertularia. They had simple or branched polyparies, formed of a chitinous substance, and the polyparies were usually strengthened by a horny-like rod, which is called the 'solid axis.' Professor Nicholson thinks that the term 'solid' is probably a misnomer, and that the axis was most likely hollow and filled with living material. The cellules in which the polypites lived were arranged in a single series on one side of the axis, or in a double series on both sides; the axis was generally prolonged beyond the cells at the growing end of the polypary. Reproductive buds, or ovarian vesicles, have been observed attached to the polypary, exhibiting a method of reproduction similar to that in the hydrozoa, but they differ from the ovarian vesicles of the modern Sertularians in becoming detached from the parent colony. The graptolites appear to have been free-floating organisms. They are generally divided into Monoprionidian and Diprionidian groups. In the first named the polypary, whether single or branched, had only one row of cellules, or 'hydrothecæ;' in the second the polypary was furnished with a row of cellules on each side. The former group ranges from the base to the top of the Silurian system, while the latter is confined chiefly to the Lower Silurian. To this system the graptolites may be said to be confined. Numerous species have been described, and from their abundance in the argillaceous shales and greywackes it is obvious that they must have swarmed in the Silurian seas. There are several other Sertularian-like fossils often described as graptolites; such as *Dendrograptus*—a rooted plant-like form (Cambrian and Lower Silurian); *Dictyonema*, also plant-like, and probably rooted (Silurian); *Retiolites*, with no solid axis (Silurian), but otherwise resembling the graptolites.

Graslitz, a town of Bohemia, on the border of Saxony, 142 m. WNW. of Prague by rail. Musical instruments are manufactured. Pop. 9780.

Grasmere, a Westmorland village, 4 miles NW. of Ambleside. There are four hotels. Pop. 684. Its antique church is the church of the *Excursion;* and in the churchyard, washed by the Rothay, are the graves of Wordsworth and Hartley Coleridge. 'Grasmere's peaceful lake,' with its 'one green island,' lies ½ mile to the south, between Loughrigg Fell (1101 feet) and Helm Crag (1299). Measuring 1¼ by ½ mile, it is 208 feet above sea-level, and 130 feet deep.

Grass-cloth. This name is sometimes given by travellers and missionaries to different kinds of coarse cloth, made by various savage races, the fibre of which is rarely that of a grass. Cloth is, or at least has been, made from Bamboo (q.v.), and a coarse matting is made from Esparto (q.v.), both of which are true grasses. A fine cloth is woven from the fibre of a species of Bœhmeria (q.v.), popularly called China-grass, but the plant is really a nettle.—To the nettle order also belongs the so-called Queensland Grass-cloth plant (*Pipturus argenteus*), which yields a fine, strong fibre.

Grasse, a town in the French department of Alpes-Maritimes, is situated on the southern slope of the Basses-Alpes, 1066 feet above sea-level, and 12 miles N. of Cannes by rail. An ancient place, the seat of a bishopric from 1244 to 1801, it has steep, narrow, crooked streets, a cathedral, and an interesting hôtel-de-ville. Grasse is second only to Paris in its manufactures of essences and perfumes, made from the roses, orange-flowers, heliotropes, mint, &c., which, thanks to the mildness of the climate, are most successfully grown in the neighbourhood. It has also manufactures of olive oil, silk, &c., and is growing in favour as a winter resort. Pop. 9786.

Grasses form the order Gramineæ, which with Cyperaceæ (Sedges) makes up the second great division (Glumaceæ) of Monocotyledons (q.v.). The first division (Petaloideæ) consists of orders whose flowers are of the liliaceous or orchidaceous type; while the flowers of Glumaceæ are best described as 'grassy.' The following characters are sufficient to distinguish grasses from sedges: grasses have generally cylindric or compressed jointed stems, usually with internodes becoming hollow; leaves alternate with sheath clasping the stem, but edges of sheath not joined; embryo at one side of the base of the endosperm (albumen). Sedges have generally triangular, sometimes cylindric, stems, jointed but solid; leaves in three vertical rows with leaf-sheath entire and forming a hollow cylinder round the stem; embryo within the base of the endosperm. The term 'grass' is often applied to any herbaceous plant that helps to form pasture, and agriculturists speak of natural and artificial grasses, the former only belonging to Gramineæ. Cereals (q.v.) and some pasture grasses are annual, but most pasture and woody grasses are perennial. Cereals and pasture grasses are herbaceous; bamboos are woody and may grow to a height of 100 feet in one season. There are 250 genera of grasses, and 3200 distinct species; of these 41 genera with more than 100 species are natives of the British Isles, and fully 800 species and varieties within the limits of the United States.

Description. The *leaves* are long and tapering, one being given off at each node of the stem; the leaf-sheath is a modified stalk, and is often prolonged upwards for a short distance beyond its junction with the blade, into a membrane or ring of hairs (ligule), which forms a collar round the stem. The parallel veins of the leaves are continued downwards into the stem and anastomose only at the nodes. The *stem* (culm) at first consists of solid nodes and internodes, but the internodes, except in sugar-cane and a few other tropical grasses, become hollowed out, and thus the

Fig. 1.

A, spikelet of wheat: *a*, glumes; *b*, awn of outer bract; *c*, barren terminal flower; *d*, stamen. B, vertical section of same spikelet: *e*, ovary; *f*, stigma; *g*, inner bract. C shows position of lodicules (*l*, *l*) in relation to the ovary.

stem is rendered comparatively lighter, and at the same time better able to resist the lateral pressure of the wind; because a cylinder offers more resistance to pressure than does a solid rod of the same

weight and kind of material. The stems of grasses are further strengthened by impregnation with silica. Annual grasses have tufted, fibrous *roots*, but most grasses perennate by means of solid underground stems (rhizomes), from the nodes of which roots are developed; roots also grow freely from the lower nodes of the aerial stems of all grasses. The *flowers* are mostly hermaphrodite, as in barley and oats; maize and a few others are monœcious; and some of the fescue tribe have the lower hermaphrodite and the upper male. Each flower is enclosed by two bracts (paleæ), which are the homologues of the two spathe-like bracts in the Inflorescences (q.v.) of Iridaceæ. The posterior bract is two-nerved, indicating its two-fold nature, and often clasps the fruit when mature; the anterior ('flowering glume') surrounds both, and sometimes bears an Awn (q.v.), as in barley. A number of flowers may be crowded together to form a spikelet; and, further, a number of such spikelets may be attached by stalks to a central axis, forming a raceme, as in *Melica nutans* (fig. 2); when the raceme is loosely branched, the inflorescence becomes a panicle, as in Oats (q.v.); or the spikelets may be sessile on a central axis, forming a compound spike, as in ryegrass (Lolium). The spike may be looked on as a reduced raceme or panicle, in which the stalks of the spikelets have not been developed; each spikelet may again be reduced to a single flower, and then a simple spike like that of mat-grass (*Nardus stricta*) is the result. Beneath the lowest flowers of many spikelets there are two bracts (glumes) which may or may not bear barren flowers in their axils. There is no perianth such as is found in most insect-pollinated flowers. Grass flowers are wind-pollinated and generally inconspicuous; in some, however, there are two or rarely three scales (lodicules) within the flower bracts; and these, from their position and relation to the other parts of the flower, may be regarded as segments of a rudimentary perianth. These scales, becoming turgid at the period of sexual maturity, press the anterior bract outwards, and expose stigmas and stamens for pollination. Should wet weather occur when this stage is reached the powdery pollen may become clogged and kept from being blown about; thus preventing fertilisation and the opportunity of producing seed.

Fig. 2.

A, *Melica nutans*; inflorescence a raceme of spikelets. B, *Lolium perenne*; a compound spike. C, *Nardus stricta*; spikelets reduced to one flower each.

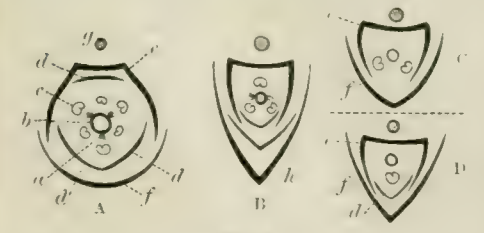


Fig. 3.

A, floral diagram of Bambusa (for explanation, see article Flower): *a*, stigma; *b*, ovary; *c*, stamen; *d*, lodicule; *e*, inner bract; *f*, outer bract; *g*, stem. B, Avena: *h*, glume; stamens reduced to three. C, Coleanthus: lodicules awanting; two stamens. D, Monandraura: one stamen.

Stamens vary from six or more to one; in British grasses usually three, but three to one in the fescue tribe. The slender filaments are inserted at the bases of the anthers, but the anther lobes grow downwards below the point of insertion, and the anthers appear to be, but are not, versatile. The *ovary* is one-celled; there are three or two styles, with long and hairy, or short and feathery stigmas, which are thus enabled to catch the wind-borne pollen. The fruit is one-seeded (*caryopsis*); the *seed* is adherent to the pericarp. The *embryo* by the great development of the farinaceous endosperm is displaced to one side at the base of the latter, its surface of contact being confined to that of a large process of disputed homology, the scutellum. When a grain of wheat or other grass begins to germinate, the scutellum acts as a placental surface to the embryo, digesting the substance of the endosperm, and passing it on in a soluble state to the embryo, which soon begins to develop roots and leaves. When all the endosperm has been used up the seedling grass has put forth roots enough to draw a sufficient supply of sap from the soil, and green leaves to transform the sap into food materials for the tissues of the plant. The scutella of grains may be compared to the suckers (haustoria) of mistletoe, for it is by means of suckers that plant parasites fix upon, and draw sap from, their hosts.

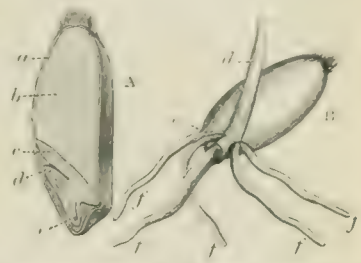

Fig. 4.

A, grain of wheat in vertical section: *a*, pericarp; *b*, endosperm; *c*, scutellum; *d*, young stem and leaves (plumule); *e*, first root (radicle). B, grain of wheat after germination has begun: *f*, secondary roots.

Classification.—The order is divided into two divisions, the divisions into tribes, genera, and species. The genera are omitted here, and only the better-known species are given as examples.

(*a*) *Paniceæ.*—Spikelets articulate with the pedicels below the lowest glume, with a single terminal fertile flower, while the lower inferior is male or sterile.

Tribe	Examples.
Paniceæ	Panicum; Setaria.
Maydeæ	Job's Tears (Coix); Maize (Zea).
Oryzeæ	Rice (Oryza); Cut Grass (Leersia).
Tristegineæ	Arundinella.
Zoysieæ	Tragus.
Andropogoneæ	Sugar-cane (Saccharum); Durra (Andropogon); Millet (Sorghum).

(*b*) *Poaceæ.*—Spikelets usually articulated above the lowest glume, 1- or many flowered; male or imperfect flower above the fertile ones.

Tribe	Examples.
Phalarideæ	Reed Canary Grass (Phalaris); Sweet Vernal Grass (Anthoxanthum); Fox-tail Grass (Alopecurus).
Agrostideæ	Millet Grass (Milium); Timothy Grass (Phleum); Bent (Agrostis).
Aveneæ	Hair Grass (Aira); Soft Grass (Holcus); Oats (Avena).
Chlorideæ	Dog's-tooth Grass (Cynodon); Eleusine.
Festuceæ	Reed (Phragmites); Dog's-tail Grass (Cynosurus); Cock's-foot Grass (Dactylis); Melic Grass (Melica); Quaking Grass (Briza); Poa; Fescue; Brome.
Hordeæ	Rye (Secale); Ryegrass (Lolium); Wheat (Triticum); Barley (Hordeum); Mat Grass (Nardus).
Bambuseæ	Bambusa; Arundinaria.

Distribution.—Grasses are almost universally distributed on land, and are found at all elevations up to the snow line, wherever there is soil. In temperate climates they form natural pastures, but in warm regions they are more tufted, and, like the sugar-cane and many bamboos, often attain a great height. The species of a single genus have often widely different habitats—e.g. *Poa annua* is a low growing field grass, while a closely allied species, *P. aquatica*, forms tall reed-like growths by the margins of rivers and lakes. The distribution of grasses in time dates from the Upper Eocene (q.v.) and subsequent formations.

Uses. The seeds of cereals furnish the principal material for *Bread* (q.v.) in most countries. By the process of malting, the starch of grains is converted into sugar, which is then allowed to undergo alcoholic fermentation; *Beer* or *Ale* (q.v.) is made in this way from barley, and from this liquor *Whisky* (q.v.) is obtained by distillation. *Sugar* is also obtained directly from the juices of some grasses, e.g. Sugar grass (*Sorghum saccharatum*), unripe maize, and Sugar-cane (q.v.). *Rum* is the fermented and distilled liquor produced from the sugar of sugar-cane. Some grasses form Pasture (q.v.) and Fodder (q.v.). A few are *medicinal*, as Job's Tears (*Coix lachryma*) (q.v.); the reeds, *Phragmites communis*, *Calamagrostis*, and *Arundo Donax*; and Couch grass (*Triticum repens*), the rhizomes of which form a mild diuretic. Very few have poisonous properties. Darnel (q.v.) is held by some to be poisonous. Coldstream (*Grasses of N. Punjab*) says: 'There is a curious fact regarding the qualities of *Sorghum vulgare* as food for cattle—viz. that in a dry season, before it flowers, the plant is poisonous to cattle. This poisonous quality is also shared by its congener, *S. halepense*.' Some grasses are *fragrant*: Sweet Vernal Grass (*Anthoxanthum odoratum*) contains coumarine, a crystalline aromatic substance which gives the sweet scent to meadow hay. Some East Indian grasses are even more strongly scented, as Lemon-grass (*Andropogon citratum*) and others of the same genus, which yield grass-oil. The woody stems of bamboos and other large grasses are applied to a great variety of economical purposes; and the straw of many of the smaller grasses is used for thatching, rope-making, plaiting, &c. (see STRAW-MANUFACTURES). Thus the fibres of the Moonja (*Saccharum Munja*) of India, the Esparto (q.v.) of Spain, and a few others are made into ropes, mats, sacks, and other coarse fabrics. *Paper* is made in China from the young shoots of bamboo; and in most civilised countries from the straw of esparto, rye, wheat, barley, and oats. All grasses, by means of their roots, help to fix the soil, and prevent it being washed away by rain and floods.

See Parnell's 'British Grasses,' and 'Gramineæ' in Engler's *Pflanzenfamilien*. For classification, see also Bentham and Hooker's *Genera Plantarum*. The U.S. Department of Agriculture has published several valuable bulletins and monographs on American grasses, by Dr George Vasey.

Grasshopper, a name given to numerous insects forming the family Locustidæ, included in the order Orthoptera, and nearly related to Crickets (Gryllidæ) and Locusts (Acrididæ). It is unfortunately confusing that 'locusts' are not included in the family Locustidæ, and that one of our commonest grasshoppers is *Locusta viridissima*. It must be noted that in this article 'grasshoppers' mean the majority of Locustidæ. Whether grasshoppers are herbivorous or, as is oftener the case, carnivorous, they usually live among vegetation, in woods and thickets or in the open field, keeping quiet during the day, but making the woodsides merry with their love 'songs' in the summer evenings. Most of them feed on flies and caterpillars, in catching which they use their powerful fore-legs, but many affect plants, and some combine both diets. During their courting season they may be seen flying even in the afternoon, but they are predominantly nocturnal and twilight insects. By their frequent green colour and yet subtler mimetic characters they are in many cases well concealed in their leafy haunts. The family is large and world-wide in distribution, but best represented in tropical and temperate regions.

In the grasshopper family (Locustidæ) the head is placed vertically; the slender antennæ are longer than the body; there are hemispherical eyes, but rarely eye-spots; wings and wing-covers are generally present. The right (and occasionally also the left) wing-cover of the male bears posteriorly

Grasshopper, Female (*Locusta viridissima*).

a clear, round membrane stretched on a ring, which produces the well-known 'chirp' when set in vibration by the action of a serrated ridge on the under side of the opposite wing-cover. The left wing-cover is the bow, the right is the fiddle of the male grasshopper's music. There is usually a well-developed auditory organ at the base of the anterior legs. The females have a long ovipositor.

Sexually mature grasshoppers appear in late summer and autumn. The eggs are laid by means of the ovipositor either in the earth or in some dry stem. From these in spring larvæ are developed, which are virtually like the adults, but moult at least six times before they become full-grown.

The Great Green Grasshopper (*Locusta viridissima*), common in Europe, and occurring in Britain, has a body over an inch long. Equally large is *Decticus verrucivorus*, also British, which owes its specific title to the habit Swedish peasants have of making it bite their warts, which the secretion of a fluid from the mouth of the insect is said to affect favourably. Very common in Europe are *Thamnotrizon cinereus*, *Platycleis grisea*, and other species. Among American grasshoppers *Conocephalus ensiger*, type of those with a conical forehead, is very common, as are also various species of Xiphidium and Orchelimum. The nearly allied Katydids (e.g. *Cyrtophyllus concavus* and *Microcentrum retinerris*—will receive separate notice (see KATYDID). The tropical genus Copiophora is noteworthy for the length of its ovipositor, which sometimes attains a length of two inches, while Phyllophora and Phylloptera deserve mention for the exceedingly leaf-like appearance of their wing-covers. See CRICKET, KATYDID, LOCUST.

Grass-moth (*Crambus*), a genus of small moths, allied to the Clothes-moths. The species, which are numerous, inhabit pastures, where they may be often seen to rise in great numbers when disturbed, and soon to settle again on the blades of grass. Their form, when their wings are closed, is long and narrow, pointed at the head, abruptly cut off at the opposite end. They are often brown and white, sometimes silvery and golden.

Grass of Parnassus (*Parnassia*), a genus of plants belonging to the natural order Saxifragaceæ.

The popular and also the botanical names are founded on the myth that the best-known species (*P. palustris*) first appeared on Mount Parnassus, the abode of grace and beauty. The plant is a native of bogs and moist heaths in Britain and throughout northern Europe and Russian Asia, becoming a mountain plant in southern Europe and west central Asia. The calyx is deeply 5-cleft, the petals white, 5 in number, and there are 5 perfect and 5 imperfect stamens, the latter bearing instead of anthers a tuft of 10 to 12 globular-headed hairs. There are several other species natives of Asia and North America.

Grass-oil, a name under which several volatile oils derived from widely different plants are grouped. The grass-oil obtained by distillation from the leaves of *Andropogon waranc̃usa* is used for rheumatism, and has the same stimulant effect as cajeput oil. Ginger-grass Oil is obtained from *A. nardus*, a native of India, and other species of the same genus. Geranium Oil, derived from *Pelargonium radula*, is so like ginger-grass oil in its properties that they are used for the same purposes, and are bought and sold under either name, mainly as an adulterant of Oil of Rose. Turkish Grass-oil is obtained from *A. pachnodes*, indigenous to India, Persia, and Arabia. Lemon-grass Oil, or Citronella Oil, is derived by distillation from *A. schœnanthus*, indigenous to India and cultivated in Ceylon. It has an odour resembling oil of citron, and is largely used for scenting soap. Cyperus-grass Oil is extracted from the tubers of *Cyperus esculentus*, indigenous to southern Europe, and is used both as a table oil and in the manufacture of soap.

Grass-tree (*Xanthorrhœa*), a genus of plants of the natural order Liliaceæ, natives of Australia, and constituting a very peculiar feature in the vegetation of that part of the world. They have shrubby stems, with tufts of long wiry foliage at the summit, a long cylindrical spike of densely aggregated flowers shooting up from the centre of the tuft of leaves. The base of the inner leaves of some species is eatable, and forms, particularly when roasted, an agreeable article of food. It has a balsamic taste; and all the species abound in a resinous juice, which, on exposure to the air, hardens into a reddish-yellow inodorous substance with a shining fracture, soluble in alcohol, and useful as a tonic in dysentery, diarrhœa, and other intestinal maladies; used also by the natives of Australia for uniting the edges of wounds, and with an aluminous earth for caulking their canoes, and as a cement for various purposes.—The Common Grass-tree (*X. hastilis*) has a stem about four feet high, but sometimes a foot in diameter. It is of very slow growth, and is supposed to be many centuries old when it has reached such dimensions.—Several species are found in eastern Australia and also in New Zealand, where their leaves are used as fodder for all kinds of cattle.

Grassum, in the law of Scotland, is a lump sum paid by persons who take a lease of landed property. 'Rent,' says Bell, 'is naturally periodical, but sometimes part is paid in anticipation in grassum. And so grassum is, when analysed, a proportion taken from each year's rent, and paid at once by anticipation, either to supply some necessity for ready money, or to disappoint some future possessor of the estate.' In England the words 'premium' in some cases, and 'fine' in others, mean the same thing.

Grasswrack (*Zostéra*), a genus of plants of the natural order Naiades, one of the few genera of phanerogamous plants which grow amongst seaweeds at the bottom of the sea. The leaves are narrow and grass-like, and the flowers consist merely of stamens and pistils, without any perianth, inserted on the central nerve of one side of a flat thin linear *spadix*, with a leafy *spathe*. The pollen is confervoid.—The Common Grasswrack (*Z. marina*) is a perennial plant, which forms green meadows on the sandy bottom of shallow parts of almost all the European seas, and abounds in creeks and salt-water ditches. It is found in great plenty on the British shores. It becomes white by exposure to the air. The rush-like coverings of Italian liquor-flasks are made of it: it is much used for packing glass bottles; and it serves well for thatch. Cattle eat it as forage; it is burned to obtain soda, and has been employed in the manufacture of paper. It has been long used in Holland, Iceland, and elsewhere for stuffing pillows and mattresses; and this use has of late years very much extended, so that the plant has become an article of commerce, under the name of *Alga marina*, or more commonly, but incorrectly, *Alva marina* (Ger. *See-gras*).

Grate. See WARMING.

Gratian, a Benedictine monk, who at Bologna between 1139 and 1142 compiled the *Decretum Gratiani*. See CANON LAW.

Gratianus, AUGUSTUS, Roman emperor from 375 to 383, was the eldest son of Valentinian I., and was born at Sirmium in Pannonia in 359. At nine he was elevated by his father to the rank of *Augustus* at Ambiani, or Amiens, in Gaul, and next year accompanied him in his expedition against the Alemanni, in order to learn the art of war. On the death of Valentinian the troops elevated Gratian to the throne, giving him at the same time as a colleague his half-brother Valentinian II. Gaul, Spain, and Britain fell formally to Gratian's share, but as his brother was only four years old he virtually ruled also over the rest of the western empire, fixing his residence at Treviri (*Trèves*). At first he showed vigour in repelling the incursions of the turbulent barbarians, and suddenly found himself in 378, on the defeat and death at Adrianople of his uncle Valens at the hands of the Goths, sovereign also of the eastern empire. Finding himself inadequate for the task of ruling the whole empire, he recalled Theodosius from Spain, and appointed him his colleague on the 19th January 379. Gratian possessed some admirable virtues: he was pious, chaste, temperate, and eloquent; but his character was too pliant, and he was often led to commit gross acts of cruelty and tyranny. His persecution of the pagans, and afterwards of heretic Christians, made him a great favourite with orthodox ecclesiastics, but rather alienated the affections of his subjects generally; while his fondness for frivolous amusements and unworthy associates excited the contempt of the army, so that when Maximus was proclaimed emperor by the legions in Britain crowds of the disaffected flocked to his standard. Gratian was defeated by him near Paris, and fled to Lyons, where he was put to death 25th August 383.

Grati'ola, a genus of plants of the order Scrophularineæ. *G. officinalis*, or Hedge Hyssop, found in most parts of Europe, is extremely bitter, a violent purgative, diuretic, and emetic, and in overdoses an acrid poison; but as a medicine was formerly called *Gratia Dei* ('Grace of God').

Gratry, ALPHONSE, Catholic theologian, born 30th March 1805 at Lille, became General-vicar at Orleans, professor at the Sorbonne, and member of the Académie. He wrote a *Cours de Philosophie*, a work on the creed, a commentary on Matthew, and *La Morale et la Loi de l'Histoire* (1868). He confuted the policy of the Vatican Council, but submitted himself, and died 25th November 1871, leaving *Souvenirs de ma Jeunesse*.

Grattan, HENRY, one of the greatest of Irish patriots and orators, and, like Curran, Flood, Isaac Butt, and Parnell, a Protestant, was born in Dublin, July 3, 1746. His father was recorder of the city, and one of its members from 1761 till his death in 1766; his mother was daughter of Thomas Marlay, Chief-justice of Ireland, one of whose sons lived to become Bishop of Waterford. At seventeen he entered Trinity College, Dublin, and here gave himself with remarkable eagerness to the study of classics. Already Henry Flood had been forming a regular party of opposition in the Irish House of Commons, and young Grattan embraced his reforming principles with such impolitic ardour that his irate father disinherited him from such property as he could alienate. At twenty one he entered the Middle Temple, London, and read law in a desultory fashion, nourishing his peculiar ambition the while by listening to the debates in the House of Commons and by constantly declaiming in set terms to imaginary audiences in the privacy of his chamber. In 1772 he was called to the Irish bar, and three years later, through the influence of the genial and enlightened Earl of Charlemont and by the advice of Flood, entered the Irish parliament as member for the borough of Charlemont. It was but two months before that Flood had thrown away his popularity by accepting office under government, and the young orator leaped at one bound into his place. He found the nation fast drifting to bankruptcy and ruin from the loss of market that followed the war with America, and the odious restrictions upon Irish trade that had come down from the days of William III.; and he at once flung himself with all the vehemence of his nature into the cause of retrenchment and reform.

Meantime, in the dread of French invasion, the volunteer movement spread from Belfast over Ireland, and ere long the attitude of the people in their demand for free export became so formidable that Lord North, whose own inclinations had formerly been thwarted by the interested opposition of the English manufacturers, granted in 1779 a total repeal of all the restriction acts. This gained, Grattan plunged into a greater struggle for nothing less than legislative independence. On the 19th April 1780 he made perhaps his greatest speech, concluding with a memorable series of resolutions to the effect that while the crown of Ireland was inseparably annexed to that of England, the king with the consent of the parliament of Ireland was alone competent to enact laws to bind Ireland. After fifteen hours the debate was adjourned indefinitely, but all men felt that Grattan had gained a great moral victory. The popular demands were formulated at the Convention of Dungannon (February 15, 1782), and asserted by Grattan in a famous speech (April 16), which began with the words, 'I am now to address a free people.' A month later the Rockingham ministry, which numbered among its members Grattan's friend Fox, surrendered apparently unconditionally, and the Irish parliament in gratitude voted Grattan a reward of £50,000. Unfortunately the question was soon raised whether the mere repeal of the Declaratory Act (6 Geo. I. chap. 5) was sufficient as a renunciation of the principle of England's right to legislate for Ireland. Grattan wished his countrymen to trust to the generous instincts of English honour, and accept the gift without factious wrangling about the manner of its giving, but Flood put himself at the head of the malcontents, demanding 'simple repeal' and renunciation rather than concessions granted merely to the exigency of the moment. He carried the mass of his countrymen with him, and what was perhaps the historic moment for the reconciliation of England and Ireland was lost. The quarrel between the two leaders culminated in one dramatic scene on the floor of the house, when Grattan overpowered his antagonist with a tornado of rhetoric that has perhaps never been surpassed for the ruthless energy of its invective.

The history of 'Grattan's parliament,' as it has deservedly been called, did not correspond to the patriotic dreams of its great founder. It was impossible for a parliament so little really representative and so much subject to corruption and undue influences from without to rise into the region of real statesmanship. In his ideas about the rights of his Catholic fellow-countrymen Grattan was far more advanced than most of his own followers. Apart altogether from the fact that the Roman Catholics, comprising two-thirds of the whole population, were entirely without representation; out of a house of 300 members no fewer than two-thirds were nominated by but a hundred patrons. The urgent need of parliamentary reform and the remedy of domestic abuses soon occupied the minds of all Irish patriots, the high-minded and the self-seeking alike. Once more at Dungannon there assembled on September 8, 1783, as many as 500 delegates to formulate the demands for parliamentary reform, which were presented to the house by Flood and rejected, while Grattan looked on in a kind of neutrality that was perhaps a consequence of the recent quarrel. He devoted himself to advocating the reform of special abuses, but his Place and Pension Bill, as well as his bills to prevent revenue officers from voting at elections, and offices of state being given to absentees, and for the commutation of ecclesiastical tithes, were in turn rejected.

Meantime continued commercial depression had produced a strong counter-feeling in Ireland for protection, which was yet unable to prevent the Secretary Orde's remedial measure for absolute free trade from being carried. This measure, however, Pitt found himself unable to carry in the English House of Commons, except subject to a number of stipulations, one of which was that all English navigation laws now and hereafter were to be adopted as such by the Irish parliament; and to this Grattan and the Irish patriots found themselves unable to accede, as an outrage upon the freedom of the Irish parliament. Pitt's mortification at this and his displeasure at the independent attitude of the Irish parliament in the regency dispute of 1789 helped to confirm his determination that union was the only effective means of final pacification. Grattan was returned for the city of Dublin in 1790, and by this time he had definitely taken up the cause of Catholic emancipation. The corruption of the Castle government and of a parliament venal beyond all precedent; the persistent repression of the agitation for Catholic relief, changed for a moment into hope at the appointment of Fitzwilliam as Lord-lieutenant, only to be dashed to the ground again by his withdrawal; and the spirit of discontent generated by the French Revolution that was now everywhere in the air had fomented the movement of the United Irishmen, which was to be extinguished in the bloodshed of 1798. Hopeless of his country and broken by ill-health, Grattan retired to his house at Tinnehinch on the eve of the rebellion, but returned to take his seat for Wicklow in the last session of the Irish parliament. Weak as he was he fought the bill for the Union with an heroic courage that would have overcome everything but the gold and the coronets of Pitt, pouring his showers of invective upon the head of Corry the Chancellor of the Exchequer, who retorted with a challenge, and in the duel was wounded in the arm. Once more Grattan retired to private life, from which he emerged in

1805 as member for Malton in Yorkshire, and for Dublin the following year. His first speech in the English House of Commons fully sustained his oratorical reputation. It contained the well-known passage about the Irish parliament: 'Of that assembly I have a parental recollection. I sat by her cradle; I followed her hearse.' The remaining energies of his life were devoted to the cause of Catholic emancipation, which he reiterated was the price of the union, apart altogether from the intrinsic justice of the demand. 'A great majority cannot overcome a great principle. God will guard his own cause against rank majorities. In vain shall men appeal to a church cry, or to a mock thunder; the proprietor of the bolt is on the side of the people.' Instead of one-sided 'securities' he demanded from his opponents adequate reasons for their opposition—'some apology to after ages for inflicting on one-fourth of their fellow-subjects political damnation to all eternity.' Despite all his eloquence and the support of Canning and other statesmen, he was not to see triumph in his lifetime. In December 1819 his health began finally to give way; but as he grew weaker his responsibility to this question weighed the more upon his mind. On the 20th of the following May he crossed from Dublin, a dying man, to speak once more for the cause, and, unable to bear the motion of a carriage, was carried to London from Liverpool by canal. But his voice was never to be heard again. A day or two after his arrival he sank, a prayer for his country on his lips, June 4, 1820. He was buried in Westminster Abbey beside the grave of Fox.

Grattan's figure was small and spare; his face long, thin, and slightly marked by smallpox. His gestures in speaking were violent and eccentric, and his voice of no great volume, yet he wielded his listeners at will by his energy and passion, his overpowering earnestness and enthusiasm. He was a consummate master of epigram, and few orators have had his rapidity and vigour. His description of Flood as standing 'with a metaphor in his mouth and a bribe in his pocket' is but one among a hundred phrases that will never be forgotten. His patriotism was enlightened and incorruptible, and his honour remains without a stain.

The best collection of his *Speeches* is that made by his son, Henry Grattan, M.P. (4 vols. 1822), who also edited in the same year his *Miscellaneous Works*. The standard Life is also that by his son (5 vols. 1839-46), but this is far from being a satisfactory work. See also the sympathetic essay in W. E. H. Lecky's *Leaders of Public Opinion in Ireland* (2d ed. 1872); Dunlop's excellent study in the 'Statesmen' series (1889); and Lecky's *England in the Eighteenth Century*, vols. vii and viii.

Gratuitous Deed, in the law of Scotland, means a deed granted without any value received. Such deeds, if made after the contracting of debt, and in favour of a near relation or confidential friend, are presumed to be fraudulent and so null. In England gratuitous deeds are usually styled Gifts (q.v.).

Gratz, or GRAZ (formerly *Grätz*), the capital of Styria, in Austria, 141 miles SSW. of Vienna by rail, is a picturesque old town with four suburbs, built on both sides of the Mur, and encircled by fine gardens and pleasure-grounds. Of the former fortress, erected on a hill in the centre of the town, and dismantled in 1809 by the French, two towers and other remains still exist. The town itself contains several old buildings, as the Late Gothic cathedral (1462), two other Gothic churches (one built in 1283), the ancient castle of the Styrian dukes, the Landhaus, where the nobles of the duchy held their meetings, the university, originally founded in 1586 (with 1134 students in 1885, and a library containing 120,000 volumes), an armoury, palaces of the Styrian nobles, and four monasteries dating from the 16th and 17th centuries. There are also national archives, a cabinet of coins and antiquities, a technical school (Johanneum), a second library of 70,000 volumes, and a botanic garden. The most important of its many industries are the manufacture of machines, steel goods, rails and railway carriages, sugar, wine, perfumery, stearine candles, soap, &c. Fat capons, biscuits, and chocolate figure prominently as articles of trade. Gratz is a favourite place of residence for Austrian officials retired from service. Pop. (1890) 112,069, including a garrison of 5000 men. The town is mentioned in the annals as early as 881. In 1481 it repulsed the Hungarians from its walls, and in 1532 the Turks. In 1797, and again in 1809, it was occupied by the French. In the vicinity are several hydropathic establishments and holiday resorts. See Ilwof and Peters, *Geschichte und Topographie der Stadt Graz* (1875).

Graubünden. See GRISONS.

Graudenz, an old town in the province of West Prussia, on the Vistula, 37 miles N. of Thorn. It carries on a trade in corn, wool, and cattle, and has iron-foundries, breweries, and tapestry and cigar manufactories. Pop. (1875) 14,553; (1890) 20,385. About a mile north of it on a hill (282 feet) is the fortress of Graudenz, built in 1776, and successfully defended against the French in 1807. It was maintained as a fortress till 1874, and now serves as a barrack and military prison. Pop. 2072.

Grauwacke. See GREYWACKE.

Gravel, the name given to aggregations of water-worn and rounded fragments of rocks, varying in size from a pea to a hen's egg. When the fragments are smaller, the deposit is sand; when larger, it is called shingle. Beds of gravel occur in formations of every age. While the materials have been a long time in being prepared, and have travelled perhaps a great distance from the mother-rock, gravel deposits have been formed speedily and by the action of a strong current of water. They form very irregular and limited deposits, occurring generally as banks or hummocks in strata of sand. Unless in the most recent deposits, they almost always form a hard rock called conglomerate or puddingstone, the pebbles being compacted together by some infiltrated cement, either calcareous, ferruginous, or siliceous in character. Even recent gravels are sometimes formed into a compact concrete, though these and later deposits are generally loose. The stones of a gravel or conglomerate may be fragments of almost any kind of rock; but the harder species are the most common—pebbles of quartz and quartzite forming as a rule the chief material in gravel-beds of all ages. In our own day gravel and shingle are formed both by fluviatile and marine action, and the same was the case in the older periods of the earth's history. Thus certain conglomerates mark out for us the sites of old sea-coasts, while others represent old river-beds.

Gravel varies much in character and appearance according to the formation from which it is derived. In the making of roads and walks, particularly in gardens, pleasure-grounds, and public parks, it is the last ingredient used. Essential qualities in a good gravel are (1) that it should be binding—that is to say, it should not shift like sand under foot; (2) it should be durable; and (3) its colour should be agreeable to the eye and in harmony with vegetation. It is rare to find a gravel in which all these qualities are combined. The only sort known in Britain to possess them all in itself is the famous *Kensington* gravel, which has long been regarded by landscape-gardeners at home and on the Continent as the most perfect natural walk or

road-finishing material obtainable anywhere. It is a pit-gravel, and abounds in oxide of iron, to which it owes its binding quality and also its fine warm harmonious colour. Many other pit-gravels also possess this cohesive property in a high degree, but are defective in colour. As possessing better binding properties, pit-gravels generally are to be preferred to sea or river gravels; but their defects of colour often preclude their use in landscape-gardening. The Kensington gravel is costly and difficult to procure. On this account, and also because of its similarity in colour, the most popular gravel of the present time is the *Dorset Pea*; but it is also one of the most shifting, the flinty pebbles composing it being round and about the size of a pea. As the name implies, this sort comes from the coast of Dorsetshire. From the shore of the neighbouring county, Hampshire, is obtained another pleasingly coloured flint-gravel named the *Lymington*; and the Sussex coast furnishes two sorts named *Sussex Pea* and *Sussex Bean*. The prevailing form of the former is pea-like, that of the latter bean-like; hence their respective names in commerce. They are found commingled on the shore, and are separated by sifting. Shell-gravel —so called because composed of minute shells entire or the fragments of larger ones—is also a favourite gravel, being pleasing in colour and comfortable to walk upon when not laid on very deep. It is found on various parts of the British coasts and on those of the Channel Islands. Musselburgh gravels—both shore and pit—are prized in that district, being good in colour, and the pit variety has also fair binding properties. There are many manufactured gravels, such as granite, whinstone, marble, quartz, slag, glass, &c., which are crushed in machines, and afterwards riddled to the desired sizes. These and all the sea and river gravels are used in making asphalt and other composite roads and paths, some of them when skilfully combined with cement imparting a very beautiful appearance to the surface.

Gravel, a disease. See CALCULUS.

Gravelines, a fortified town in the French department of Nord, is situated in a marshy locality at the mouth of the Aa, 13 miles by rail ENE. of Calais. A desolate-looking place now, with grass-grown streets, it has an historic past, as the scene of Egmont's victory over the French (1558), and the place off which the English dispersed the Armada (1588). It was taken by the French in 1644, retaken by the Austrians after a ten weeks' siege in 1652, and finally recaptured in 1658 by Louis XIV., who had it fortified by Vauban. Pop. (1872) 4391; (1891) 4125.

Gravelotte, a village of Lorraine, 7 miles W. of Metz. There, on 18th August 1870, the French under Bazaine sustained a severe defeat by the Germans. See FRANCE, Vol. IV. p. 783.

Graves. See BARROW, BURIAL, CHURCHYARD, CEMETERY, MONUMENTS.

Graves, ROBERT JAMES, physician, who did much to raise the status of his profession in Ireland, was born in 1797, the youngest son of the Dean of Ardagh. He studied medicine at Dublin, and after taking his degree visited the medical schools of London, Göttingen, Berlin, Copenhagen, those of France and Italy, and Edinburgh, and on his return home settled (1821) in his native city as a private practitioner and a teacher of medicine, especially distinguishing himself by the introduction of improved methods of clinical study. In 1827 he was appointed professor of the Institutes of Medicine in the College of Physicians, Dublin, of which college he was chosen president in 1843 and 1844. He was elected a Fellow of the Royal Society in 1849. Many of his most remarkable papers appeared in the *Dublin Journal of Medical Science*, which was founded by him in 1832. Dr Graves died on 20th March 1853. He published *A System of Clinical Medicine* (1843) and *Clinical Lectures* (1848). After his death his *Studies in Physiology and Medicine* was issued in 1863 by Dr W. Stokes. See *Dublin University Magazine*, 1842.

Gravesend, a port and borough of Kent, on the right bank of the Thames, 24 miles ESE. of London. It consists of the old town, with narrow, irregular streets, and of the handsome new town on the high ground. In the vicinity are extensive market-gardens; and many of the inhabitants are employed in fishing. Gravesend forms the limit of the port of London; and here pilots and custom-house officers are taken on board of vessels going up the river. For centuries the prosperity of the town has depended on its connection with the metropolis. The salubrious air and beautiful scenery at Gravesend render it a favourite watering-place with Londoners. It carries on some shipbuilding, iron-founding, soap-making, and brewing, and a considerable trade in supplying ships' stores. Gravesend was incorporated under Elizabeth, and since 1867 has returned one member to parliament. Pop. (1861) 24,525; (1891) 35,492, of whom 24,067 were within the municipal boundary. Gravesend was originally a *hythe*, or landing-place, and is mentioned as such in Domesday. Around this landing-place a town grew up soon after the Conquest. Here the fleets of early voyagers, as that of Sebastian Cabot in 1553, and of Martin Frobisher in 1576, assembled, and here the lord mayor, aldermen, and city companies of London were wont to receive all strangers of eminence, and to conduct them up the river in state. A great fire in 1850 did damage to the amount of £100,000. See Arden's *History of Gravesend* (1843).

Gravina, a town of southern Italy, in the centre of a rich agricultural district, 33 miles SW. of Bari. Pop. 15,612.

Graving-dock. See DOCK.

Gravitation. It is a matter of common experience that all unsupported bodies near the surface of the earth fall to the ground, the direction of their motion being towards the earth's centre. The modern explanation of this phenomenon is that it is due to an attractive force termed gravitation or gravity, which exists between any such body and the earth, in virtue of which they tend to move towards one another. The motion of the earth and other planets round the sun, and of the various satellites round their primaries, may be explained on the same ground. The mode of action of this force is given in the following generalisation, first explicitly given by Newton, and known as the *Law of Gravitation*: Every particle of matter in the universe attracts every other particle with a force whose direction is that of the straight line joining the two, and whose magnitude is proportional directly as the product of their masses, and inversely as the square of their mutual distance.

Previous to Newton's investigations, Kepler, by a truly prodigious amount of labour, had deduced from the observations of Tycho Brahe the following kinematical laws of planetary motion: (1) The path of each planet is an ellipse, of which the sun occupies one focus; (2) the radius-vector (i.e. the straight line which joins the centre of the sun to that of the planet) of each planet describes equal areas in equal times; (3) the square of the periodic time (i.e. the time during which a planet makes one complete revolution round the sun) of each planet is proportional to the cube of the major axis of its elliptic orbit. From the second of these

deductions Newton showed that if the sun attracts the earth or other planet, the direction of this attractive force must be in the line joining their centres; from the first and third he proved that its intensity must be inversely proportional to the square of their mutual distance (so that at double that distance the intensity of attraction would be one-fourth; at three times the distance, one-ninth; and so on). Lastly, the proof that the attraction is proportional to the product of the masses is found in the fact that the weight of any body is under all circumstances proportional to its mass. To test the truth of his deductions, Newton studied the motion of the moon round the earth, and found that this satellite is retained in its orbit by an attraction which is exactly the same as that which causes a body near the earth's surface to fall with an acceleration of (about) 32·2 feet per second.

It must, however, be remembered that Kepler's laws are themselves only approximately true, owing to the attraction of one planet on another interfering with what might be termed the ideal state of things, and thus producing those small superposed motions of a planet which astronomers have termed *perturbations*. But it is just in this that the confirmatory proofs of the law of gravitation are found; for not only are all these perturbations completely explained by its means, but they have also been discovered and measured by it.

The action of gravitation is independent of the *nature* of matter, thus differing from magnetic attraction, which is only found in a restricted class of bodies. At the same time the manner in which magnetic and also electric attraction depends upon distance is the same as gravitation. Gravitation is not affected by the presence of other matter; in other words, the weight of a body is the sum of the weights of its parts.

The intensity of gravity at the earth's surface is measured by the acceleration of a body falling freely under its influence; it is usually denoted by g. It is found, from pendulum experiments, to vary slightly with the latitude, and also with the height above sea-level of the observing station. For any locality in the British Islands it is, however, little different from 32·2 feet per second. The following table gives the value of g for several places in the northern hemisphere:

Station	Latitude	Value of g in feet per second
Equator	0° 0′	32·091
Paris	48° 50′	32·183
Greenwich	51° 29′	32·191
Berlin	52° 30′	32·194
Dublin	53° 21′	32·196
Manchester	53° 29′	32·196
Edinburgh	55° 57′	32·203
Aberdeen	57° 9′	32·206
North Pole	90° 0′	32·255

From these figures it will be seen that a body apparently gains weight as it is carried from the equator to higher latitudes. This is due to two causes. First, owing to the ellipsoidal shape of the earth, gravitational attraction at the poles is $\frac{1}{500}$ greater than at the equator; (2) owing to the 'centrifugal force' of the earth's axial rotation, bodies at the equator are $\frac{1}{289}$ lighter than at the poles, where this cause does not affect their weight. These two fractions together make up the difference, $\frac{1}{194}$, between equatorial and polar gravity. The fraction denoting diminution of weight due to the centrifugal force of the earth's rotation, may be employed to find at what speed the earth would need to revolve in order that gravity would just be balanced by 'centrifugal force.' It is found that, to fulfil this condition, the earth would require to revolve at seventeen times its present speed; when revolving at this rate bodies would not have any tendency to remain on the earth's surface, and with an increased speed they would be projected into space. Taking also into consideration the diminution of gravity with increase of height, the value of terrestrial gravity is expressed by the formula $g = 32{\cdot}173 - {\cdot}082 \cos 2\lambda - {\cdot}000003\, h$ where λ is the latitude, and h the height, in feet, above sea-level. It must be remembered that this value of g is different from that which would be obtained were there no axial rotation of the earth; under the latter circumstances, the value of gravitational attraction alone would be $g = 32{\cdot}525 - {\cdot}026 \cos 2\lambda$.

To account for the phenomenon of gravitational attraction several theories have been advanced; but in spite of the best efforts of mathematicians and physicists, the real cause remains undiscovered. Nor is there any physical reason in evidence of the truth of the several assumptions upon which these theories have been based. As Clerk-Maxwell has pointed out, their chief value lies in their suggestiveness, and in there being an incentive to the deeper and more prolonged research after possible causes for gravitation. The earliest speculations on the subject were, of course, almost wholly metaphysical, and therefore misleading, if not absolutely erroneous. To begin with, the assignment of an attraction between the earth and sun as the cause of the earth's motion was set down as being impossible, on the plea that a body could not act in the place where it was not. Again it was urged that such a cause would be simply 'action at a distance,' and hence impossible. Newton's only speculation on the subject showed that he looked to some intervening medium as the agent by means of which attraction between bodies was exerted; that if bodies rarefied this medium round them at a rate lessening as the distance increased, gravitational attraction might thus be accounted for. Another hypothesis, and one of an entirely novel kind, was put forward in 1818 by Le Sage. He presupposed that space contains an exceedingly large number of small bodies moving rapidly in all directions. To these bodies he gave the name of ultramundane corpuscles. They would impinge upon any single isolated body in space in all directions, the result being that the body would not be moved, the impacts being equal on both its sides. But with two bodies in space, one would screen the other from a certain number of blows, so that on their opposed faces there would be a fewer number than on their distant faces; in consequence of this excess of impacts on one side over those on the other, each body would tend to move towards the other. The attraction between the two would be inversely as the square of their distance, and proportional to the surface of the bodies resolved normally to the line joining their centres. So that if mass be proportional to surface, there should be coincidence between the results of the hypothesis and the observed law. The chief objection to this hypothesis is that it would require not only that the corpuscles be infinitely small compared with the molecular distances in ordinary matter, but that they move at a speed enormous compared with anything we are acquainted with. Moreover the amount of energy required to maintain the gravitational attraction of a comparatively small body near the earth's surface would, if converted into heat, be sufficient to raise the earth to the temperature of incandescence. Sir William Thomson has shown that gravitation might be explained by the assumption of the existence of an incompressible fluid filling all space, being either created in each particle at a rate proportional to its mass, and flowing off everywhere to an infinite distance; or by each particle absorbing a quantity proportional to its mass, the supply coming in all directions from an infinite distance. Another method of accounting for gravitation is that of

Clerk Maxwell, who showed that if in a medium, such as that of the luminiferous ether, there be pressure along, and tension at right angles to the lines of force, the effect would be an attraction such as that of gravitation. The main objection to all these proffered hypotheses is that they presupposed the existence of quantities of energy in the universe which are absolutely enormous compared with the effects they produce; or, at all events, postulate some cause working not in accordance with the known laws of energy.

Gravity, SPECIFIC. See SPECIFIC DENSITY.

Gray, a town in the French department of Haute Saone, on the Saone, which is here crossed by a stone bridge of the 13th century, 25 miles NW. of Besancon. It has remains of an ancient castle of the dukes of Burgundy, some trade in corn, flour, and iron, and iron-industries and boat-building. Pop. 6737.

Gray, ASA, an eminent American botanist, born at Paris, Oneida county, New York, November 18, 1810. He took his degree of M.D. in 1831, but soon relinquished the practice of medicine, and devoted himself to his favourite study of botany. In 1834 he received the appointment of botanist of the United States exploring expedition to the southern seas; but, as a long delay took place before it was ready to sail, he resigned his post in 1837. He was afterwards elected professor of Botany in the university of Michigan, but declined the appointment, and in 1842 became Fisher professor of Natural History at Harvard. In 1873 he retired from the chair, but still retained charge of the great herbarium he had presented to the university in 1864; and in 1874 he succeeded Agassiz as a regent of the Smithsonian Institution. He ranks among the leading botanists of the age. His numerous writings evince equal ability in communicating elementary knowledge and in elucidating recondite theories. He came forward at a time when the old artificial systems of botany were giving way to the natural system which has taken their place, and he was the first in America, in conjunction with Dr John Torrey, to arrange the heterogeneous assemblage of species upon the natural basis of affinity; and he became an influential supporter of the Darwinian theories of evolution. In 1838 he commenced, with Dr Torrey, the *Flora of North America;* and in 1848-50 appeared the *Genera Florae Americae Boreali-Orientalis Illustrata.* Among his remaining works may be mentioned, besides memoirs on the botanical results of several government exploring expeditions, and a number of text-books that have long been in general use in the United States, *A Free Examination of Darwin's Treatise* (1861), *Darwiniana* (1876), and *Natural Science and Religion* (1880). He died 30th January 1888. A selection from his scientific papers was published in 2 vols. in 1889. He was a member of the principal learned societies of both America and Europe, to whose transactions and to periodicals he contributed much. His *Letters,* edited by Jane L. Gray, appeared in 1893.

Gray, DAVID, a minor poet, was born 29th January 1838, at Duntiblae, on the south side of the Luggie, about 8 miles from Glasgow. He was the eldest of the eight children of an industrious weaver, who gave him as good an education as he could at the Normal School and university of Glasgow, in the hope of making him a Free Church minister. But the boy began early to write verses, and seems to have made from the beginning an enormously exaggerated estimate of his own promise. In May 1860 he started for London along with Robert Buchanan, with the usual lofty hopes, and quickly met the usual discouragements. He made an appeal to Monckton Milnes, afterwards Lord Houghton, who found him some employment, but failed to get his poems printed. Meantime consumption seized him, and a stay in Devonshire, for which Milnes, Sydney Dobell, and other friends had found him the means, proving useless, he went home to his parents at Merkland, a mile from Kirkintilloch, to die. The end came quickly, 3d December 1861, but the day before he had had the happiness to hold in his hand a specimen page of the volume of his poems in print. The volume was entitled *The Luggie and other Poems* (1862), and was prefaced by an introduction by R. Monckton Milnes and a memoir by J. Hedderwick. His latest work was his best, and, indeed, the sonnets grouped together here under the title 'In the Shadows' are stamped with a solemn and touching beauty of their own. An enlarged edition, edited by Sheriff Glassford Bell, appeared in 1874. See also R. Buchanan's too high-pitched essay, in *David Gray, and other Essays* (1868).

Gray, ELISHA, an American inventor, was born at Barnesville, Ohio, 2d August 1835, and studied at Oberlin College, meanwhile supporting himself by working as a carpenter. He was afterwards engaged in the manufacture of telegraphic apparatus. His patents number about fifty, including several for the speaking telephone, of which he claims the invention, and others for a multiplex telegraph, by which he has succeeded in sending eight messages at a time.

Gray, JOHN EDWARD, English naturalist, born at Walsall in 1800, was educated for the medical profession. After assisting his father, author of *Supplement to the Pharmacopoeia,* in the preparation of his *Natural Arrangement of British Plants* in 1821, he entered in 1824 the British Museum as assistant in the Natural History Department, and in 1840 was appointed keeper of the Zoological Collections, a post which he retained till 1874. A few months later, on 7th March 1875, he died in London. To him belongs the merit of having made the zoological collections of the British Museum the most complete in the world. Dr Gray wrote much on subjects connected with his department. The titles of his books and papers number more than 500. Of these the most important are his catalogues of the British Museum collections, which are not mere lists, but are enriched with synonyms and ample notes. Next to these come *Illustrations of Indian Zoology* (1830-35) and *The Knowsley Menagerie and Aviary* (1846-60). Dr Gray also assisted in the formation of some of the most prosperous scientific societies of London, and was a vice-president of the Zoological Society.—His wife, MARIA EMMA, wrote *Figures of Molluscous Animals for the Use of Students* (5 vols. 1842-57).—His brother, GEORGE ROBERT GRAY (1808-72), an officer in the Zoological Department of the British Museum from 1831 till his death, is known as author of *The Genera of Birds* (1849), and of works on the birds of Polynesia and New Guinea.

Gray, THOMAS, one of the greatest of English poets, in value if not in bulk, was born in Cornhill, London, 26th December 1716. His father, Philip Gray, a money-scrivener, was of so violent and jealous a temper that his wife (Dorothy Antrobus) was obliged to separate from him, and it was mainly through her own exertions that the boy was placed at Eton, and afterwards at Cambridge, where two of her brothers were fellows of colleges, and afterwards tutors at Eton. Both the mother and her sister Mary loved the boy with a devotion that was rewarded by a life-long and passionate attachment. In 1727 he was sent to Eton, whither in the same year also came Horace Walpole, son of the prime-minister. As a boy Gray was shy and studious, and he carried the same temper to

Peterhouse, which he entered in 1734. The predominant mathematics in the studies of Cambridge were distasteful to his mind, and a habitual but passive melancholy early seized and mastered him. In the March of 1739 he was prevailed upon by Walpole to accompany him on the grand tour. They spent the next two and a half years visiting the towns and exploring the picture-galleries of France and Italy, and Gray's letters home reveal not only an exquisite taste in art and music, but also the first touch of that romantic love of nature which Rousseau was soon to make so fashionable. The two friends quarrelled at Reggio and parted. Walpole afterwards took the blame entirely on himself, and certainly by his efforts the breach was healed within three years, and the friendship never again interrupted. Gray reached England in the September of 1741, and seems now to have begun seriously to write poetry, his *Ode on Eton College* being written in the autumn of 1742, and the *Elegy* at least begun. In the winter he went back to Peterhouse, took his bachelorship in civil law, and became a resident there. For the next four or five years he studied Greek literature profoundly, and busied himself with abortive projects for editions of Strabo, Plato, and the Greek Anthology. This was perhaps the happiest period of his life, while he breathed the serene air of noble libraries, and was as yet untroubled by brøken health. He found his relaxation and his keenest pleasure in the company of his friends, and in writing, when absent from them, letters such as only men at that time could write. His holidays were spent with his mother and aunt at Stoke Poges, with Walpole at London, Windsor, and Strawberry Hill, or in travelling in different parts of the country. From his letters we see that he had a quick eye for the variety and colour of nature, and certainly he was almost the first of modern Englishmen to see the beauty as well as the horror in the Highland mountains—those 'monstrous children of God.'

In the summer of 1747 Dodsley printed Gray's famous *Ode on a Distant Prospect of Eton College*, and early next year reprinted it with two other pieces in his *Miscellany*. The death of Gray's aunt, Mary Antrobus, in the November of 1749 appears to have brought back to his recollection his *Elegy*, and he seems about June 1750 to have finished it where he began it seven years before—at Stoke Poges. This humane and stately poem is perhaps the best-known piece of English verse, a masterpiece in the balanced perfection of a metre that beats true to the pulse of human sympathy in the solemn alternation of passion and reserve, and especially happy in a subject that can never lose its interest for mankind. The poem was sent to Walpole, was handed about in manuscript, and soon became so well known that Gray was forced to print it in the February of 1751. Early in March 1753 appeared in a thin folio the *editio princeps* of Gray's collected poems, with designs by Bentley, only son of the famous Master of Trinity. Gray's mother died 11th March 1753, and was buried at Stoke Poges, with an exquisitely simple and affecting epitaph from her son's pen upon her tombstone.

Walpole said that Gray was 'in flower' during the years 1750–55, and during this period he commenced his most ambitious poems, the *Pindaric Odes*, the splendidly resonant *Progress of Poesy*, perhaps his really greatest work, being finished by the close of 1754. *The Bard*, begun at the same time, was not completed till the summer of 1757. Gray had long had a nervous horror of fire, and had fixed a rope-ladder from his window in Peterhouse by which to escape in emergency. One night in February 1756 he was roused from sleep by a pretended alarm of fire, and, without staying to put on his clothes, descended from his window into a tub of water that had been placed under his window by some frolicsome undergraduates. Displeased at the authorities of Peterhouse for not punishing this brutal practical joke, the poet migrated in 1756 to Pembroke Hall, where he spent the remaining fifteen years of his life surrounded by congenial friends, in the midst of his books, his china, his pictures, and his flowers. His two odes were printed at Strawberry Hill in 1757, and were admitted to have put their author at one bound at the head of living English poets. The laureateship was offered him in 1757 on Colley Cibber's death, but declined. During the years 1760 and 1761 he devoted himself to early English poetry, of which he intended to write a history; later he made studies in Icelandic and Celtic verse, which bore fruit in his Eddaic poems, *The Fatal Sisters* and *The Descent of Odin*—genuine precursors of romanticism. In 1768 he collected his poems in the first general edition, and accepted the professorship of History and Modern Languages at Cambridge, an office which entailed no duties and yielded an income of £400 a year. Johnson in his perverse life of Gray made, from 'a slight inspection of his letters,' one solitary remark that showed insight, that Gray 'was a man likely to love much where he loved at all.' Certainly no silent and melancholy poet was ever more happy in his friendships, and few men have been loved with such singleness and devotion. His biographer Mason's affection was not entirely disinterested, but the love of friends like Nicholls, Bonstetten, Robinson, Wharton, Stonehewer, and Brown proves that there must have been some singular charm in the object on which it was lavished.

Gray's latest journeys were made to Glamis Castle and to the Cumbrian lakes, the beauties of which he was the first to discover. He was now comparatively rich, and enjoyed a reputation peculiarly dear to a scholar's heart, and his life glided quietly on, troubled only by fits of dejection and by attacks of hereditary gout. As he was dining one day in the college hall at Pembroke, a severe attack seized him, and after a week's suffering he died, 30th July 1771. He was buried fittingly by his mother's side in his own Country Churchyard—Stoke Poges.

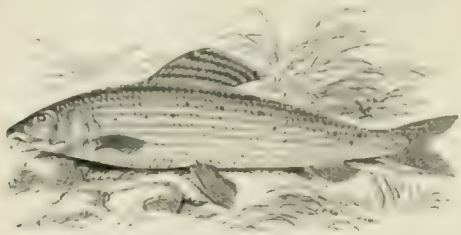
Gray said of his own poetry that 'the style he aimed at was extreme conciseness of expression, yet pure, perspicuous, and musical.' The excellence he aimed at he attained, and in his lyrical work, moreover, he reached in a high degree the Greek quality of structure, especially in his *Pindaric Odes*. 'I do not think,' says Edward Fitzgerald, 'that his scarcity of work was from design: he had but a little to say, I believe, and took his time to say it.' At anyrate all his work bears the stamp of dignity and distinction, and it was perhaps as much the fault of the chilling atmosphere of his age as of his own hyper-refinement of taste or intermittency in the fits of creative fancy that its quantity was so little. Yet this slender garland of verse has been sufficient to give Gray his rank among the *dii majores* of English poetry.

The earlier Lives of Gray and editions of his works by Mason and Mitford have been superseded by the study by Edmund W. Gosse (1882) in the 'English Men of Letters' series, and by the same editor's complete edition of his works in prose and verse, including as many as 349 of his letters (4 vols. 1884). See also the essay by Matthew Arnold in vol. iii. (1880) of T. H. Ward's *English Poets*.

Gray's Inn, one of the four Inns of Court (q.v.) in London.

Grayling (*Thymallus*), a genus of fresh-water fishes in the salmon family, distinguished from trout, &c. by the smaller mouth and teeth, and by the long many-rayed dorsal fin. The genus is

represented by five species, inhabiting clear streams in north Europe, Asia, and North America. The British Grayling (*Th. vulgaris*) has a wide but local distribution; it prefers rivers with rocky or



Grayling (*Thymallus vulgaris*).

gravelly bottom and an alternation of stream and pool. The back and sides are silvery gray, with longitudinal dusky streaks; the dorsal fin is crossed by rows of spots. The fish, which may attain a weight of 4 to 5 lb., is esteemed for the table, but should be cooked when newly caught, when it has an odour compared to that of wild thyme. It spawns in April or May, and is in best condition when trout are out of season, in October and November. Another well-known species is *Th. signifer*, a beautiful fish from the clear affluents of the Mackenzie River, called 'Hewlukpowak,' or 'fish with the winglike fin,' by the Eskimos, and 'poisson bleu' by the Canadian voyageurs. See Pritt, *The Book of the Grayling* (1888); Walham, *Grayling, and how to catch them* (1895).

Graystone, Graywacke, &c. See GREYSTONE, GREYWACKE, &c.

Graz. See GRATZ.

Grazalema, a town of Spain, situated in a very strong natural position 53 miles ENE. of Cadiz. Its 8000 inhabitants are principally engaged in manufacturing cloth and in smuggling.

Grease, a term of general application to all oily or fatty matters, but generally to those having some degree of solidity, as tallow. It is more specially applied to fatty matters which are so deteriorated by dirt or other impurities as to be unfit for candle-making and other manufactures requiring some degree of purity in the material. Grease is largely employed as a lubricant for heavy machinery, and especially for the wheels of carriages. The grease employed for the axles of wagons and carts consists of inferior kinds of grease mixed with a little tar. On English railways grease is used for goods and mineral wagons; for passenger carriages palm oil is used. See LUBRICANTS. For a disease of horses, see WEED.

Great Basin, a remarkable triangular plateau of North America, occupying the western portion of Utah and nearly the whole of Nevada, as well as a section of Oregon and California, and extending at its north-eastern angle into Idaho. It is bounded on the W. by the Sierra Nevada, and on the E. by the Wahsatch Mountains. The base of the triangle, in the N., is some 500 miles from east to west; it extends from N. to S. for nearly 800 miles, and its area is slightly greater than that of France. It is girdled round on every side by high mountains, and traversed throughout by numerous ranges, frequently parallel, yet as often irregularly blending or crossing; the valleys are usually sinks, the chief drainage centre being Great Salt Lake (q.v.), and the Humboldt and Carson sinks, at about the same elevation. It has been pointed out by the United States Geological Survey that the Great Basin's areas of greatest depression are to be found near the borders, while its central portion reaches a much greater elevation. The loftiest range is the East Humboldt, near the middle, which culminates in Mount Bonpland (11,321 feet). Volcanic masses form or conceal the original rocks of many of these ranges. The Great Basin contains many streams and lakes, the latter for the most part salt, whose waters never reach the ocean, but are either taken up by evaporation or sink in the desert sands. The mean annual rainfall ranges in different localities from 4 to 15 inches. The plateau is nearly destitute of trees, and in general only the upper parts of the valleys are clothed with desert shrubs, their lower portions often being occupied either by bodies of water or by a muddy bottom covered with several inches' depth of alkaline salts left by evaporation.

See, besides reports to the United States Geol. Survey, works by I. C. Russell on Lake Lahontan (1883 and 1885) and Southern Oregon (1884); and Hague, *The Volcanic Rocks of the Great Basin* (1884).

Great Bear Lake. See BEAR LAKE, GREAT.

Great Britain. Under this head are noticed (1) the island of Great Britain—its geology and geography; and (2) the United Kingdom of Great Britain and Ireland—its general statistics, &c.

Great Britain was so called to distinguish it from Britannia Minor, or Brittany, in France (see BRITANNIA). The name was a poetical or rhetorical expression till in 1604 James I. styled himself king of Great Britain, although the term was proposed in 1559 by the Scottish Lords of the Congregation. Lying between 49° 57′ 30″ and 58° 40′ 24″ N. lat., and between 1° 46′ E. and 6° 13′ W. long., Great Britain is the largest island of Europe. It is bounded on the N. by the Atlantic, on the E. by the North Sea, on the S. by the English Channel, and on the W. by the Atlantic, the Irish Sea, and St George's Channel. The most northerly point is Dunnet Head, in Caithness; the most southerly, Lizard Point, in Cornwall; the most easterly, Lowestoft Ness, in Suffolk; and the most westerly, Ardnamurchan Point, in Argyllshire. Its greatest length is about 608 miles, and its greatest breadth (from Land's End to the east coast of Kent) about 325 miles; while its surface contains 88,226 sq. m.

Geology.—The geology of Great Britain is of peculiar importance. The fossiliferous strata having been first systematically studied and expounded here, British geologists have given to the world the names whereby most of the larger divisions and subdivisions of these strata are known. Nearly all the recognised 'systems' occur in Britain, although some of these are more fully represented elsewhere. Indeed, the only system not found in Britain is the Miocene—the beds formerly classed as of this age being now included in the Oligocene. British geology is no less important from the influence it has had in the development of the country. The mineral wealth, especially the coal and the iron, are the real sinews and muscles of Britain's mighty power. No other country has similar advantages in such an area. (See also the article on the geology of EUROPE.)

We shall, in this sketch of the distribution of the British rocks, follow the order of the strata, beginning with the lowest and oldest. It may be said that, in general, the mountainous regions of the north and west are formed of the oldest rocks, and that, as we move south-eastwards, we gradually pass over newer strata, until, in the east of England, we come to the uppermost divisions of the Tertiary.

The base rocks of the whole series occur in the Outer Hebrides, in Rona, Tiree, and Coll, and along the western shores of Sutherland and Ross. They are assigned to the Archæan System (q.v.), and consist chiefly of coarse gneiss, usually hornblendic,

and various schists, with occasional crystalline limestones—the whole series being veined more or less abundantly with pegmatite. Small isolated areas of Archæan occur also in England (Charnwood Forest, the Wrekin, the Malverns). No fossils are met with in any of the Archæan rocks.

The oldest fossiliferous strata in Britain belong to the Cambrian System (q.v.), and are well developed in Wales and Shropshire, attaining a thickness of more than 30,000 feet. They consist chiefly of dark-red and purple sandstones, grits, and conglomerates, with green slates and slaty shales. The fossils are not abundant, but show a remarkable variety of forms. In Scotland the Cambrian appears to be represented by the red grits, conglomerates, and sandstones which rest directly on the Archæan rocks of the outer Hebrides and the north-west Highlands.

The *Silurian System* (q.v.) occupies a large portion of the surface of the country. The typical rocks occur in Wales, extending over the western portion of the principality from Pembroke to Denbigh, and including the northern portions of Pembroke, Carmarthen, and Brecknock, the whole of Radnor and Montgomery, the south-west of Denbigh, and the whole of the counties to the west. The oldest or Lower Silurian beds are next the coast. The series consists of an immense thickness of shales, slates, grits, and greywackes, with intercalated limestones more or less pure. Immense tracts have hitherto proved devoid of fossils; in other districts the calcareous rocks are almost entirely composed of the remains of marine invertebrate animals, while the shales abound in zoophytes and crustacea. The high lands in the north of Lancashire and south of Westmorland are Silurian; but it is in Scotland that these strata are most extensively developed. A line drawn from Dunbar to Girvan forms the northern limit of these beds in the south of Scotland. Except the lower half of the valley of the Tweed, the whole region from this line to near the base of the Cheviots is Silurian. The rocks are chiefly greywacke, with scattered beds of impure limestone. The chief fossils are graptolites, crustacea, brachiopoda, and mollusca. The lead-mines of Wanlockhead and Leadhills are in this district. East and south-east of the Archæan and Cambrian rocks of the north-west Highlands come Silurian rocks which are more or less metamorphosed. Up to recent years geologists believed with Sir R. I. Murchison that all the schists, &c., lying to the east of the Cambrian and Archæan areas, and extending down to the borders of the lowlands in Strathmore, &c., were altered Silurian strata. Probably this is the fact, but the work of the Geological Survey in the north-west Highlands has suggested some doubts. A line drawn from Stonehaven to Helensburgh marks the southward range of those schists and slates, &c.

The *Old Red Sandstone System* (q.v.), consisting of conglomerates, coarse and fine grained sandstones, and dark-coloured flagstones and shales, with characteristic fossils of ganoid and placoid fish, overlies the Silurian in several districts in Scotland. Nearly all Caithness and the seaward portions of Sutherland, Ross, Cromarty, Inverness, Nairn, and Elgin, belong to these strata. A broad band, extending on the east coast between Stonehaven and St Andrews, stretches across the country to Helensburgh and Dumbarton on the west. The same strata appear again in Haddington, Berwick, and Roxburgh, in Lanark, and in Ayrshire. Old Red Sandstone likewise occurs in South Wales and the neighbouring English counties, extending from the Silurian district to the Severn and the Bristol Channel, and containing in a large basin the South Wales coalfield. The highly fossiliferous strata of north Devon, and of south Devon and Cornwall (Devonian system) are believed to be on the same geological horizon as the Old Red Sandstone. They consist of slates, sandstones, and limestones, and contain numerous corals and shell-fish.

The *Carboniferous System* (q.v.) may be said to occupy a broad tract extending from the Bristol Channel to the base of the Cheviots. The strata are not continuous between these limits, but are broken up in some places by the appearance on the surface of older strata, while in others they are covered by newer deposits. The various detached coalfields are (1) the South Wales, in Glamorgan and Pembroke; (2) the Bristol, and (3) the Forest of Dean, in Gloucester; (4) the Forest of Wyre, in Worcester; (5) Shrewsbury, and (6) Coalbrookdale, in Shropshire; (7) north and (8) south Staffordshire; (9) Warwickshire; (10) Leicestershire; (11) Flint and Denbigh; (12) Lancashire; (13) York and Derby; (14) Cumberland; and (15) Northumberland and Durham. In the northern portion of this great tract of carboniferous strata, where the millstone grit and carboniferous limestone are largely developed, few seams of coal of any value are contained. The limestone in Derby is rich in metallic ores. The carboniferous strata of the north of England extend beyond the Cheviots into Scotland, forming a narrow band from the Solway to the North Sea, in the counties of Dumfries, Roxburgh, and Berwick. The only coalfield in this district is one of small extent at Canonbie, in Dumfriesshire. The carboniferous strata in Scotland, with the exception just stated, are confined to the immense trough between the Silurian and Old Red Sandstone systems on the south and the Old Red Sandstone on the north, which is completely occupied by them, except where underlying older strata rise to the surface. Considerable tracts of sandstone and limestone without coal break up the coal-bearing beds into the following coalfields: the Midlothian, the Fife, the Lanark and Stirling, the Ayrshire, the Sanquhar in Dumfriesshire. Beside coal, the whole of the carboniferous series contains immense stores of argillaceous carbonate of iron, from the ore of which is produced the great bulk of the iron used in the country. The sandstones of this period form beautiful and durable building-stones, the limestones are of great commercial value, and many of the less indurated shales are good fireclays.

The *Permian System* (q.v.), consisting of magnesian limestone and sandstone coloured with oxide of iron, occupies a considerable area in Durham, and borders the carboniferous rocks in Dumfries, Cumberland, Westmorland, Lancashire, Cheshire, Shropshire, Stafford, Worcester, Warwick, Nottingham, and York, and in Glamorgan. The sandstone is quarried for building.

The typical triple series of the *Triassic System* (q.v.) occurs in Germany; the British representatives consist of variously-coloured sandstones and marls. They occupy a considerable surface in Lancashire, Cheshire, Shropshire, and Stafford, and extend as a ribbon of varying breadth, from the mouth of the Exe, through Devon, Somerset, Gloucester, Worcester, Warwick, Leicester, Nottingham, York, and Durham, to the coast at Hartlepool. The only deposits of rock-salt in Britain occur in the Triassic rocks of Cheshire and Worcestershire.

The *Jurassic System* (q.v.) is composed of an extensive series of limestones, marls, sandstones, and shales, which stretch in a broad belt from Yorkshire to Dorsetshire, passing through Lincoln, Worcester, Warwick, Northampton, Huntingdon, Bedford, Buckingham, Oxford, Gloucester, and Wilts. The best building materials in England

are obtained from these strata. Jurassic strata occur in Scotland at Brora (Sutherland), in Skye, &c. In the Brora Oolite a seam of coal 3½ feet in thickness has been worked off and on since 1820. It is the thickest bed of pure vegetable matter detected in any Mesozoic formation in Britain.

The *Cretaceous System* (q.v.), consisting chiefly of chalk with underlying sands and clays, all very rich in fossil remains, occupies a broad tract to the east of the Jurassic strata, and parallel to them. Beginning a little north of Flamborough Head, the cretaceous strata may be traced through York and Lincoln, then across the Wash into Norfolk, Suffolk, Hertford, Buckingham, Oxford, Berks, to Hampshire, where they separate into three arms, the one extending south-westward through Wilts and Dorset to the south coast; another taking a south-east direction to Beachy Head; while the third stretches as a narrow band in an easterly direction through Surrey and North Kent, widening out as it nears the coast, where it occupies the district between Ramsgate and Folkstone. The fresh water *Wealden series*, with its abundant remains of reptiles, fishes, shells, and insects, is developed chiefly over the tract that lies between the North and South Downs.

The *Eocene System* (q.v.), consisting of clays, sands, and marls, abounding in fossils which apparently indicate a subtropical climate, occupies the valley of the Thames, from Hungerford to the sea, and from Canterbury to Saxmundham, as well as a large district in Dorset, Hants, and Sussex, from Salisbury west to Dorchester, and east almost to Hastings.

The *Oligocene System* (q.v.) is very sparingly developed in Britain—the only deposits of note occurring in Hampshire and the Isle of Wight.

The *Pliocene System* (q.v.), consisting of ferruginous shelly sand and marl known as crag, occurs chiefly in Suffolk and Norfolk. The still more recent *Pleistocene System* (q.v.) is represented by superficial accumulations of alluvium, gravels, boulder-clay or till, bedded clays, &c., which are scattered over wide areas. To the same system belong the cave-deposits with relics and remains of primeval man.

Minerals.—In some respects the most important of British minerals is *coal*. The greatly-increasing consumption of coal has originated fears as to the possibility of the exhaustion of our mineral fuel (see COAL).—Formerly, the only *iron* produced in the country was obtained from the greensand of the south-east of England, and from the brown hematite of the Dean Forest. The ore was smelted with charcoal. But the introduction of coke and coal for smelting, and the discovery of numerous additional and unthought-of deposits, especially in connection with coal-bearing strata, immensely increased the production of iron, and met the greatly-increased demands for this important metal. In 1760, when charcoal alone was used for smelting, not more than 25,000 tons of iron were produced; now an average of 4,000,000 or 5,000,000 tons are obtained from some 12,000,000 or 13,000,000 of ore. The most important ore is the ferruginous shale, or impure argillaceous carbonate of iron, found in every British coalfield. The brown and red hematites, associated with the oldest Palæozoic rocks, yield much metallic iron.—*Tin* is obtained from two counties—Cornwall and Devon.—*Copper* is obtained from the same two counties, but the quantity obtained in Britain has greatly declined since 1860, and is trifling compared with what is smelted from imported ores. Other copper mines are or were in Lancashire, Carmarthen, and Anglesey (see COPPER).—*Lead* and *Silver* are obtained from the same ore from numerous mines in Palæozoic districts. The most productive English mines are in Northumberland, Durham, Cumberland, Shropshire, Yorkshire, Derbyshire, Cardiganshire, Glamorganshire, and the Isle of Man. Small quantities are obtained in Somerset, Westmorland, Stafford, and Chester. All the Silurian counties of Wales contain mines. The Isle of Man yields much ore. In Scotland the most productive mines are at Wanlock head and Leadhills.—*Zinc* is obtained chiefly from Cardigan, Denbighshire, Carnarvon, Flint, Cumberland, and the Isle of Man.—*Sulphur Ores* (iron pyrites) are raised in different parts of Great Britain.—The following minerals are also raised—viz. arsenic, manganese, gold, nickel, silver-copper, fluor-spar, and wolfram.—*Salt* occurs chiefly in Cheshire and Ulster.

The following table shows the minerals raised in the United Kingdom in 1888, with their value at the mines:

		Quantities	Value at the Mines
Arsenic clay (Blackdown)	tons	2,000	£4,850
Arsenic shale	"	1,984	248
Antimony ore	cwt.	74	7
Arsenic	tons	1,624	5,197
Arsenical pyrites	"	5,325	1,240
Barytes	"	20,191	26,147
Bog-manganese	"	10,957	5,465
China clay (kaolin or pipe-clay)	"	2,566,729	653,119
Coal	"	169,967,210	32,971,276
Cobalt and nickel ore	"	152	746
Copper ore	"	17,134	60,980
Copper precipitate	"	418	6,539
Fluor-spar	"	110	153
Gold (fine)	oz.	5,843	27,300
Gypsum	tons	120,485	58,998
Iron ore	"	14,500,715	3,501,317
Iron pyrites	"	23,507	11,302
Jet	lb.	2,217	332
Lead ore	tons	34,[illegible]	1,[illegible]58
Lignite	"	971	437
Manganese ore	"	1,342	1,074
Oil-bearing shale, &c.	"	7,173	13,387
Oil shale	"	2,076,469	519,126
Petroleum	"	35,[illegible]	
Phosphate of lime	"	22,500	43,312
Salt	"	2,305,569	700,859
Slates and slabs	"	171,788	1,057,535
Stone, &c.	"		8,694,697
Sulphate of strontia	"	7,064	3,532
Tin ore	"	14,[illegible]70	894,665
Tin-stone of soda	"	2[illegible]	54
Wolfram	"	60	1,625
Zinc ore	"	26,408	91,984
Total values.....			£59,834,997

The total value of the coal and other minerals raised in the United Kingdom was £40,345,945 in 1866, £74,094,638 in 1880, and £69,129,664 in 1895. The total value of the metals obtainable by smelting from ores produced in the United Kingdom (aluminium, antimony, copper, gold, iron, lead, magnesium, silver, sodium, tin, zinc) in 1887 was £12,795,993; in 1898, £13,717,512.

Physical Geography.—The physical features of a country are intimately connected with its geological structure. Thus the Highlands and Southern Uplands of Scotland are built up chiefly of crystalline schists and the older Palæozoic strata, while the intervening lowlands of the so-called Central Plain are composed mainly of the younger Palæozoic rocks and overlying accumulations of superficial deposits. The mountainous tracts of Scotland consist therefore of more enduring or less readily eroded materials than the lowlands. Any wide tract of the Highlands (built up largely of crystalline schists and granitic rocks), when viewed from a commanding position, looks like a tumbled ocean in which the waves appear to be moving in all directions. The mountains are massive, generally round shouldered and often even flat-topped, while there is no great disparity of height among the dominant points of any individual group. This is the result of denudation, guided and controlled by the petrological character and geological structure of the rocks. The mountains are monuments of erosion; they are the wreck of an old tableland, the upper

surface and original inclination of which are approximately indicated by the summits of the various mountain-masses and the direction of the principal rivers. The Highlands are intersected from south-west to north-east by the Great Glen, which probably occupies the line of a dislocation. It is customary in geographical text-books to speak of the 'range of the Grampians,' but the Highland mountains do not trend in linear directions, but rather form confused groups. It is probably owing to the fact that many of the rivers and streams run in certain more or less definite directions that the mountains have been described as linear ranges. The greatest height reached is 4406 feet in Ben Nevis, which is the culminating point of the Highlands (q.v.), less eminences being Ben Macdhui (4296 feet) and Ben Lawers (3984; with cairn, 4004). The southern limit of the Highlands is defined by a line drawn from the Firth of Clyde at Helensburgh north-east to the sea-coast at Stonehaven. North of this line there are of course considerable tracts of less elevated ground, especially along the coast in Aberdeenshire and the borders of the Moray Firth. Caithness is another comparatively low-lying and gently undulating plain. The coast-line of the Highlands, particularly in the west, is repeatedly broken by numerous and large fiords or sea-lochs, in which the sea is usually abnormally deep. And opposite the same coasts appear the numerous islands of the Inner and Outer Hebrides. These fiords are simply submerged land-valleys, while the islands referred to are the higher parts of the depressed continental plateau. There is reason to believe that at a very late geological date the Scottish coasts extended outwards to what is now the contour line of 100 fathoms. One of the most marked features of the Highlands is the multitude of fresh-water lakes. These vary in size from mere tarns to large mountain-valley lakes like Lochs Lomond, Ness, Awe, Shin, Maree, Tay, &c., and most of them occupy rock-basins, which are comparable in character to the deep hollows that occur in the sea-lochs.

The Central Plain of Scotland may be described as a broad depression of relatively easily eroded materials lying between two tablelands of less readily denuded rocks. The principal features of this low-lying tract have a north-east and south-west trend determined by geological structure, as is seen in the Sidlaw Hills, the Ochil Hills, the Lennox Hills, &c., in the north, and in the Pentland Hills in the south. The surface of the lowland tracts is likewise diversified by many more or less abrupt and isolated hills, such as Arthur's Seat, Dalmahoy Crags, the 'Castle-rocks' of Edinburgh and Stirling, &c. Most of these heights consist of igneous rocks of a more durable character than the strata of sandstone, shale, &c., which surround them.

The Southern Uplands of Scotland form a broad belt of high ground extending from the sea-coast of Haddingtonshire and Berwickshire south-west to the shores of Ayrshire and Galloway. Like the Highlands the area of the southern uplands is simply an old tableland, furrowed into narrow ravine and wide dale by the operation of the various agents of erosion. The general configuration of this upland tract is somewhat tame and monotonous. The mountains are flat-topped elevations with broad rounded shoulders and smooth grassy slopes. They do not run in linear directions but form irregular groups and masses. The rocks that enter into their composition are chiefly Silurian, greywackes, and shales, and consequently there is less variety of contour and colour than in the Highlands. The hills are not only flatter atop but are generally much smoother in outline, there being a general absence of those beetling crags and precipices which are so common in the Highlands. Now and again, however, the mountains assume a rougher aspect, more especially in Carrick and Galloway, where the highest point (Merrick, 2764 feet) of the southern uplands is reached. The Silurian strata are overlaid towards the south by younger Palæozoic rocks, consisting principally of sandstone and igneous rocks which gave rise to different orographic features. Thus we have the broad vale of Tweed and the lower reaches of Teviotdale occupied chiefly by sandstones and shales. The Cheviot Hills, again, are built up in the north-east chiefly of bedded igneous rocks which towards the south-west give place to sandstones that form broad elevated moors and serve to connect the Cheviot Hills with the loftier Silurian uplands lying to the north-west. In this region of sandstones, &c., not a few of the hills are conical in shape—a form due to the presence of cappings of relatively harder igneous rocks.

Crossing the borders of Scotland and England we find the high ground just referred to is continued southwards through Northumberland, Cumberland, Durham, Yorkshire, Lancashire, and Derbyshire to form what is called the Pennine Chain. This 'chain' varies in height from 1200 to 3000 feet, reaching its highest summit in Scafell Pike, Cumberland, which is 3210 feet high. When the hills are composed chiefly of sandstones and shales, they show generally a somewhat rounded and monotonous outline, but in the regions where thick limestones abound these usually give rise to more or less bold and abrupt escarpments. The Lake district of Cumberland and Westmorland, being built up mainly of Silurian rocks, reproduces the characteristic features of the southern uplands of Scotland. And the same is to a large extent true of the mountainous parts of Wales (whose highest point, Snowdon, is 3571 feet), while not a few of the features of the Scottish Highlands reappear on a small scale in Devonshire and Cornwall. All these hillier tracts are composed essentially of Palæozoic and associated igneous rocks. The major portion of England, however, consists principally of younger strata, and may be considered on the whole as a somewhat undulating plain traversed by ridges of varying elevation, which trend in a general direction from north-east to south-west. The band of Jurassic strata, extending from the Yorkshire Moors south and south-west to the coast of Dorset, forms a tortuous belt of tableland and escarpment, rising sometimes to a height of 1500 feet, and throughout its course presenting usually a bold face to the west and a gentle slope to the east. This configuration is the result of geological structure—the escarpments corresponding to the outcrop of the relatively harder members of the Jurassic system, which are underlaid and overlaid of more readily eroded strata, while the general inclination of the strata is to the east and south-east. Similar escarpments accompany the outcrop of the chalk, but they are neither so lofty nor so bold. They form the Wolds of Yorkshire and Lincoln, and rise into a low range of hills that extend from Norfolk to Wilts, the more prominent portions of which are known as the Chiltern Hills, the Marlborough Downs, and Salisbury Plain. On the north and south side of the Wealden anticlinal axis, similar chalk hills appear, forming the North Downs in Surrey and Kent, and the South Downs in Hants and Sussex. Lying between the Pennine Chain in the west, and the Yorkshire Moors and Wolds and Lincoln Heights and Wolds in the east, lies the broad depression traversed by the Ouse and Trent which is occupied chiefly by Triassic strata. In like manner, a low plain separates the mountain-tracts of Wales from the Pennine Chain, which is similarly occupied by Triassic and younger Palæozoic strata. The maritime parts of Lincoln, Norfolk, Suffolk, Essex,

and Middlesex are for the most part low lying, being composed of Cretaceous and overlying Tertiary and Quaternary deposits. Thus, in England as in Scotland, the loftier and bolder tracts of the country are met with in the regions occupied by the indurated rocks of the older Palæozoic series. It is in those regions where the most picturesque and diversified scenery occurs. A considerable number of estuaries penetrate the coast-lines of England and Scotland, south of the Highland area, but none of these recalls the characteristic features of the deep sea-lochs of the Highland seaboard. The mountain valleys of southern Scotland, of England and Wales, are not submerged—the firths and estuaries of such regions being simply the submerged lower reaches of lowland valleys. The whole surface of Britain, with the exception of the extreme south of England, has been more or less modified by glacial action, to which is largely due the rounded contour and flowing outline of all but the highest elevations. The surface-features of the low-lying tracts have also been greatly modified by the enormous morainic and fluvio-glacial accumulations which were spread over the country in Pleistocene times. Notwithstanding all such modifications, however, the prevailing influence of petrological character and geological structure in determining the orographic features of the country is everywhere conspicuous.

The physical geography of Ireland is discussed elsewhere (see IRELAND); here all that need be said is that in its geological relations it is intimately related to Great Britain—its orographic features being likewise determined by the character of its various rock-masses. Ireland, like its sister island, forms a portion of the depressed continental plateau—its highly indented coast-line, more especially in the west and south-west, being the result of a comparatively recent submergence. There can be no doubt that in post-glacial times Ireland was joined to Britain which at that period formed a part of the continent of Europe. See EUROPE (*Geology*).

Meteorology.—The climate of Great Britain derives its peculiar character from the insular situation of the country, taken in connection with the prevailing direction of the winds. It is mild and equable in a remarkable degree, the winters being considerably warmer, and the summers colder than at other places within the same parallels of latitude. For at least three months, the mean monthly temperature ranges between 50·0° and 60·0°; for other three months it continues about 60·0°, or occasionally a little higher, seldom more than four degrees; and for the remaining six months it ordinarily ranges between 36·0° and 48·0°. Since the Reports of the Registrar-general clearly prove that the temperature most conducive to health is between 50·0° and 60·0°, it follows that, as far as concerns temperature, the climate of Great Britain is one of the healthiest in the world.

As appears from data furnished by the Reports of the English and Scottish Meteorological Societies, the mean temperature of England is 49·5°, and of Scotland 47·5°. The mean temperatures of the following places, arranged according to the latitude, have been deduced from the same sources: Guernsey, 51·5; Falmouth, 51·4; Ventnor, 51·1; Barnstaple, 51·4°; Bournemouth, 50·8°; Greenwich, 50·3; Bedford, 49·9; Derby, 48·8; Liverpool, 49·3; Manchester, 48·6°; Isle of Man, 48·8°; Scarborough, 47·8; Milne Graden (Berwick), 47·5; Leith, 47·2; Rothesay, 47·8; Greenock, 47·6; Arbroath, 47·0; Culloden, 46·6°; Tongue, 46·3°; Sandwick (Orkney), 45·8°; and Bressay (Shetland), 45·0°. There is thus a difference of fully six degrees between Falmouth, in Cornwall, and Shetland. This difference is chiefly attributable to the difference of their latitudes. It becomes greater as the force of the sun's rays increases; so that, while the winter temperatures are respectively 44·2° and 39·0°, the summer temperatures are 60·6° and 53·4°. The highest summer temperature is 64·2° in London, and the lowest 52·2° at North Unst, the difference being 12·0°. A pretty regular decrease of temperature, with an increase of latitude, will be observed, particularly if the places on the west side of the island be regarded as a series by themselves. The temperatures of places on the west are in excess of those of places in the same latitudes, but at some distance from the Atlantic. In winter, the differences between the west and the other parts of the country are still greater. Thus, whilst the January temperature of Falmouth is 44·2°; Guernsey, 43·0°; Ventnor and Barnstaple, 42·0°; Isle of Man, 40·8°; Liverpool, 40·6°; and Greenock, and the whole of the west coast of Scotland as far as Shetland about 39·5°—that of Greenwich is 38·4°; Nottingham, 37·2°; York, 36·7°; Scarborough, 38·3°; Leith, 38·1°; Aberdeen, 37·3°; and Culloden, 37·5°.

The south-west winds are the most prevalent throughout the year, except in April and May, when they give place in a considerable degree to the north-east winds. The notoriously dry and parching character of the latter renders them very deleterious to health. On the other hand, the south-west winds, coming from the Atlantic, are moist and genial, and it is on their greater frequency—being, as compared with the north-east, in the proportion of two to one—that the salubrity of the British climate in a great measure depends.

In those districts of England where hills do not intervene, the annual rainfall is about 25 inches, and in similar parts of Scotland about 28 inches; but these amounts, which may be considered as the rainfalls of the driest districts of the two countries, are variously increased by proximity to hills or rising grounds, according as the place is situated in the east or west of the island, viewed in relation to the direction of the wind which brings the rain, and by its lying on the wind or on the lee side of these hills. Since it is the south-west winds which bring by far the larger proportion of the rainfall, the heaviest falls take place among the hills in the west of the country; and it may be here observed that, in the west, where there are no hills lying to the north-west, west, or south-west, the annual rainfall is only about 40 inches. Except in a few scattered and restricted districts, the amount nowhere rises above 40 inches; but over broad districts in the West Highlands and Skye, and in limited areas in the Lake district, and in North and South Wales, the annual rainfall exceeds 80 inches. At the head of Glencroe, Argyllshire, it rises to 128¼ inches, and at the Stye, Cumberland, to 186 inches. At the Ben Nevis Observatory the amount is 127 inches. Over all districts where the annual rainfall is large, or considerably in excess of the average, the greater proportion falls during the winter months; but on the other hand, where the rainfall is small, as is characteristic of all the great agricultural districts of these islands, the greater proportion falls during the summer months, and there the falls which accompany thunderstorms and east winds occasionally rival the torrential falls of equatorial regions.

Fauna.—The animals found in Britain are for the most part the same as those inhabiting similar latitudes over the whole of the North Temperate or Palæarctic region of the Old World. In fact Wallace says that the majority of genera in countries so far removed as Great Britain and northern Japan are identical. As the British Islands were formerly connected with the Continent, the general similarity is intelligible enough, while the geological changes of insulation and the restriction of area are enough to account for the one great difference that the British, and especially

the Irish species, are much fewer than those on the mainland. Insulation, however, also abets the modification of species, and thus we find a few forms peculiar to Britain, such as the red grouse (*Lagopus scoticus*), a shrew (*Sorex rusticus*), as well as some land-shells and insects. But if we exclude these few exceptions, and take account furthermore of the extinct forms, the general conclusion is simply that the British fauna resembles that of the corresponding parts of the great Palæarctic region. See works by Wallace, Murray, Sclater, Heilprin, &c., cited at GEOGRAPHICAL DISTRIBUTION.

Flora.—The British flora corresponds in a general way to that of the Continent, but appears to consist of several more or less distinct sets. The general resemblance may be shown by the fact that out of 117 plants recorded by De Candolle as characteristic of more than a third of the earth's surface, 100 occur in Britain. As to the various sets, Watson in his *Cybele Britannica* (1847) distinguishes British, English, Scottish, Highland, Germanic, and Atlantic types; while Forbes (*Mem. Geol. Soc.*, i. 336) also considered the vegetation of Britain as composed of outposts of several floras—from France, the Pyrenean region, Scandinavia, and other parts. Watson also distinguishes Agrarian and Arctic zones of distribution in Britain, each with three subdivisions marked by characteristic vegetation. The number of Phanerogams has been computed at 1600 species, and there are probably at least twice as many Cryptogams. Among the very rare flowering plants, *Oxytropis campestris*, *Lychnis alpina*, *Astragalus alpinus*, *Saxifraga cernua*, *Eriocaulon septangulare* may be noted. See Watson and Forbes as above; Loudon's *Catalogue of British Plants* (6th ed. 1867); Balfour's *Manual of Botany* (1871); Turnbull's *Index of British Plants* (after the 'Loudon Catalogue,' 1889); and Hooker's *Student's Flora*.

COMPARATIVE STATISTICS.

AGRICULTURE.—This industry no longer holds the same relative importance as in previous times of our history. It made a great start after the fall of the Stuarts, and its golden epoch was the reign of George II. (1727–60). In 1750 the agricultural wealth (as shown below) was 581 millions sterling, or 53 per cent. of the total wealth of Great Britain, as estimated in 1770 by Young. In 1887 it was under 24 per cent. of the total. If Young's estimates be correct, the number of sheep in 1774 was much greater than at present, and as for tillage, the acres under crops in 1812 (according to Comber) were only 2,000,000 less than at present. The following table shows merely the state of tillage in the three kingdoms during sixty-one years:

Year.	England.	Scotland.	Ireland.	United Kingdom.
1827....	11,140,000	2,550,000	5,450,000	19,140,000 ac.
1846....	13,300,000	3,390,000	5,240,000	21,930,000 "
1866....	13,340,000	3,170,000	5,250,000	21,760,000 "
1876....	13,920,000	3,510,000	5,210,000	22,640,000 "
1888....	13,350,000	3,690,000	4,140,000	21,180,000 "

The distribution of crops in 1888, according to the official reports, was as follows:

	England.	Scotland.	Ireland.	United Kingdom.
	acres.	acres.	acres.	acres.
Wheat	2,510,000	70,000	90,000	2,670,000
Oats	1,885,000	1,015,000	1,280,000	4,180,000
Barley, &c.	2,485,000	255,000	200,000	2,940,000
All Grain	6,880,000	1,340,000	1,570,000	9,790,000
Potatoes	445,000	160,000	805,000	1,410,000
Turnips, Vetches, &c.	2,385,000	500,000	435,000	3,320,000
Clover, &c.	3,640,000	1,690,000	1,330,000	6,660,000
All Crops	13,350,000	3,690,000	4,140,000	21,180,000
Pasture	14,590,000	1,190,000	10,920,000	26,700,000
Total	27,940,000	4,880,000	15,060,000	47,880,000

The cultivated area, as compared with total extent, is 75 per cent. in England, 75 per cent. in Ireland, and only 25 per cent. in Scotland; but the value of products is relatively highest in Scotland, as shown below. In 1887 England and Wales produced 110s. per cultivated acre, Ireland, 72s., Scotland, 163s. Thus, Scotland has only 10 per cent. of the cultivated area of the United kingdom, while the gross product of tillage and pasture reached 40 millions sterling, or 16 per cent. of the total for the three kingdoms. Respecting tillage at past dates the reader is referred to the works of Comber (1812), Middleton (1820), M'Culloch (1831), and Caird, Porter, &c., for detailed statistics. The production of grain has been approximately as follows, in millions of bushels:

Year	Wheat	Barley Oats, &c.	Total	Bushels per Inhabitant.
1830	104	304	408	17
1846	143	258	401	15
1866	98	290	388	14
1876	84	270	354	11
1887	76	235	311	8

From the foregoing table it will be seen that we produce now only 8 bushels of grain per inhabitant, against 17 in the year 1830. At present the average is 19 bushels per inhabitant in France, 15 in Germany, 42 in Denmark, 42 in United States, 34 in Canada, and 18 in Australia.

The following statistics of live-stock are for England and Wales down to 1831, and the United Kingdom afterwards:

Year	Horses.	Cattle.	Sheep.	Pigs.
1688			12,000,000	
1774			25,600,000	
1800			26,150,000	
1831	1,500,000	5,220,000	39,650,000	4,000,000
1867		8,730,000	33,820,000	4,220,000
1877	1,890,000	9,730,000	32,220,000	3,730,000
1888	1,940,000	10,270,000	28,940,000	3,820,000

The returns for 1888 show as follows:

	England.	Scotland.	Ireland.	Unit. Kingd.
Horses	1,240,000	190,000	510,000	1,940,000
Cattle	5,060,000	1,110,000	4,100,000	10,270,000
Sheep	18,580,000	6,730,000	3,630,000	28,940,000
Pigs	2,265,000	155,000	1,400,000	3,820,000

M'Culloch estimated the products of the three kingdoms in 1846 at 218 millions sterling; his table compares with the products of 1887 thus—all farm products, in million pounds sterling:

	1846.			1887.		
	Agricultural.	Pastoral.	Total.	Agricultural.	Pastoral.	Total.
England	80	62	142	92	65	157
Scotland	19	9	28	24	16	40
Ireland	28	20	48	17	37	54
United Kingdom	127	91	218	133	118	251

M'Culloch's estimate for Ireland in 1846 was perhaps too low. The Registrar-general for Ireland in December 1889 published a report on the total value of farming products, thus:

1851-55 annual average	£71,980,000
1866-70 " "	72,240,000
1884-88 " "	54,040,000

This shows a national loss of £18,200,000 per annum to the Irish people, or double the total rental of the country. In seven years, down to August 1888, the Land Court has reduced rents on 243,490 farms from £3,852,000 to £3,094,000, the saving thus effected to tenants being equal to 4 per cent. of their loss by the fall in prices.

Middleton estimated the total value of farm products of England and Wales in 1820 at 127 millions sterling; M'Culloch, in 1846, at 142 millions. In 1887 the total for the three kingdoms was 251 millions—viz.:

	1846. United Kingdom.	1887. United Kingdom.
	England and Wales.	
Crops	£81,500,000	£41,000,000
Grass Crops	28,500,000	52,000,000
Hay and Straw	17,000,000	33,000,000
Meat	26,500,000	51,500,000
Dairy	12,000,000	31,000,000
Eggs and Poultry	1,400,000	10,000,000
Fruit	3,000,000	6,000,000
Hops, Wool, &c.	4,500,000	14,000,000
Timber	1,800,000	1,500,000
Vegetables and Fruits		10,000,000
Total	£141,700,000	£251,000,000

The value of farm products in the three kingdoms in 1846 was 218 millions sterling, equal to 45 per cent. of the then estimated earnings of the whole people. In 1887 it was 251 millions, or only 20 per cent. The above figures merely express the gross product, utterly apart from profits.

The following table of agricultural capital does not include Ireland before 1814. Land is capitalised at thirty times the rental.

Year	Million pounds sterling.			
	Land.	Cattle.	Sundries.	Total.
1750	498	25	58	581
1814	1470	74	172	1716
1843	1677	91	197	1968
1868	2025	170	286	2481
1880	2086	209	295	2590
1887	1873	185	229	2287

In the preceding table an allowance of 10 per cent. is included as 'sundries,' but Chaptal and other French economists allow 14 per cent. It will be noted that the agricultural capital of the United Kingdom has only risen 30 per cent. since 1814, while the wealth of the nation (since Colquhoun's estimate in 1811) has risen 370 per cent. Agriculture, in fact, is by no means so prosperous as it was one hundred years ago, nor is the gross product so high relatively as elsewhere. The agricultural capital of the United States is only 52 per cent. higher than in the United Kingdom (the value of land being in the United States so much less); the gross product is 200 per cent. greater. Germany has the same agricultural capital as the United Kingdom, while her product is 66 per cent. over ours.

The agricultural capital and product of various nations are approximately as follows, in million pounds sterling:

	Capital.	Gross Product yearly.	Per.
United Kingdom	2287	251	10·9
United States	3496	776	21·0
Canada	413	65	15·0
Australia	413	62	15·0
France	3229	450	13·7
Germany	2296	415	17·8
Russia	2090	523	25·0
Argentine Republic	191	44	23·1

FINANCES. The revenue of the British government has been as follows:

Date.	Reign.	Amount.
1080	William I.	£1,450,000
1120	Henry I.	990,000
1250	Henry III.	264,000
1480	Edward IV.	167,000
1540	Henry VIII.	1,300,000
1610	Charles I.	950,000
1700	William III.	4,135,000
1788	George III.	9,030,000
1810	George III.	55,810,000
1830	William IV.	9,400,000
1860	Victoria.	71,100,000
1888	"	89,800,000

In the earlier reigns of the above table the nominal amount was only one-third of the above sums; but it must be remembered that the groat (4 pence) contained as much silver as our shilling of to-day. Hence the above represents the exact value in silver. The purchasing power was three times greater down to 1540 (Henry VIII.), and twice as great from that time till the death of George II. than what our present money can buy.

Revenue and expenditure since 1842 show as follows, in million pounds sterling:

Period.	Revenue.	Expenditure.
1842-51	567	549
1852-61	678	709
1862-71	711	692
1872-81	799	794
1882-88	616	619
47 years	3371	3363

The revenue was made up as follows, in million pounds sterling:

Period.	Customs.	Excise.	Stamps.	Income Tax.	Post Office.	Sundries.	Total.
1842-51	226	151	71	55	18	46	567
1852-61	267	181	78	102	30	20	678
1862-71	221	204	94	78	45	69	711
1872-81	199	268	119	51	74	77	799
1882-88	139	184	83	90	68	52	616
47 years	1022	988	456	396	235	274	3371

The expenditure was as follows, in million pounds sterling:

Period.	Services of Debt.	Army and Navy.	Civil Services.	Total.
1842-51	287	160	102	549
1852-61	285	288	136	709
1862-71	265	263	164	692
1872-81	281	280	233	794
1882-88	196	218	205	619
47 years	1514	1209	840	3363

National expenditure, not including local taxes, compares with the estimated capital wealth of the nation as follows, in million pounds sterling:

Year.	National Wealth.	Total Expenditure.	Rate of Expenditure.
1640	250	1	0·4
1700	790	4	0·5
1810	2130	56	2·6
1840	4100	53	1·3
1860	5560	71	1·3
1888	9400	90	1·0

If we include local taxation, and compare the gross public burden with the estimated earnings of the British and Irish people, we find thus, in million pounds sterling:

Year.	Total Public Expenditure.	Earnings of People.	Rate of Burden.
1840	63	560	11·6 per cent.
1850	68	620	11·0 "
1860	86	760	11·3 "
1870	107	980	10·8 "
1880	143	1170	12·2 "
1888	157	1280	12·3 "

In 1899 the actual revenue was £108,336,193, in addition to about £9,500,000 paid to local taxation in accordance with acts passed between 1888 and

1896. The National Debt, which in 1702 was £12,767,225, was in 1802 £537,653,008; in 1857 it was £837,144,597, and in 1899 £627,562,585, or about £15, 13s. 2d. per head of the population, the annual charge being about 12s. 5d. per head. See NATIONAL DEBT.

COMMERCE.—Official records of British trade (including Irish from 1820) show as follows:

Year.	Reign.	Imports.	Exports.	Total.	Per Inhabitant.
1355	Edward III.	£120,000	£290,000	£410,000	£0 2 10
1573	Elizabeth.	2,100,000	1,880,000	3,980,000	0 15 0
1687	James II.	4,200,000	4,080,000	8,280,000	1 10 2
1726	George I.	6,700,000	7,700,000	14,400,000	1 1s 0
1770	George III.	13,400,000	16,000,000	29,400,000	3 6 0
1800	"	24,100,000	43,200,000	67,300,000	6 8 0
1820	George IV.	29,700,000	44,200,000	73,900,000	3 10 0
1840	Victoria	51,600,000	62,000,000	113,600,000	4 4 0
1850	"	99,000,000	70,000,000	169,000,000	6 4 0
1860	"	210,500,000	164,500,000	375,000,000	12 17 0
1870	"	303,300,000	244,100,000	547,400,000	17 7 0
1880	"	411,200,000	286,400,000	697,600,000	20 5 0
1887	"	362,200,000	280,800,000	643,000,000	17 7 0
1888	"	387,635,743	297,885,236	685,520,979	18 6 2

The Board of Trade returns were as follows for imports:

	1854.	1870.	1887.	Estimate for consumption in 1887.
Grain (including rice and potatoes)	£22,800,000	£36,700,000	£51,200,000	£49,800,000
Raw Cotton	20,200,000	53,500,000	40,200,000	34,500,000
Manufactures	4,100,000	26,500,000	35,400,000	35,400,000
Meat (including live cattle)	3,800,000	7,700,000	22,800,000	22,400,000
Wool	6,500,000	15,800,000	24,500,000	10,700,000
Sugar	10,800,000	17,600,000	16,500,000	15,900,000
Dairy Produce	3,100,000	11,900,000	16,400,000	16,400,000
Tea and Coffee	7,200,000	15,400,000	15,000,000	10,600,000
Timber	11,500,000	13,200,000	12,100,000	12,100,000
Minerals	3,100,000	8,900,000	13,900,000	13,900,000
Wines (including spirits)	6,400,000	8,000,000	7,700,000	6,600,000
Flax and Jute	5,800,000	10,400,000	8,600,000	8,600,000
Raw Silk	6,400,000	8,200,000	2,100,000	2,100,000
Sundries	40,700,000	69,500,000	95,800,000	
Total	£152,400,000	£303,300,000	£362,200,000	

The principal exports of British and Irish products were as follows:

	1854.	1870.	1887.	
Cotton goods	£31,700,000	£71,400,000	£71,000,000	The exports for 1887 show also £59,400,000 of colonial or foreign produce not included here.
Woollen goods	10,700,000	26,600,000	24,600,000	
Linen and Jute goods	5,100,000	10,400,000	8,700,000	
Silken goods	1,200,000	2,600,000	2,800,000	
All Textiles	£48,700,000	£111,000,000	£107,100,000	
Iron	11,700,000	26,500,000	25,800,000	
Other metals	3,800,000	4,700,000	4,300,000	
Cutlery	4,100,000	6,400,000	3,100,000	
Machinery	2,200,000	5,300,000	12,800,000	
Coal	2,100,000	5,600,000	10,200,000	
Sundries	24,600,000	40,100,000	58,100,000	
Total	£97,200,000	£199,600,000	£221,400,000	

The aggregate trade in merchandise only, exclusive of bullion, for seven years ending December 1887 showed thus, in million pounds sterling:

	Imports from	Exports to	Gross Trade, 7 Years	Ratio.
United States	627	254	881	18·6
France	264	180	444	9·4
Holland	174	111	285	6·0
Germany	171	202	373	7·9
Russia	120	53	173	3·6
Belgium	102	97	199	4·2
Sweden and Norway	76	35	111	2·3
Spain	71	31	102	2·2
Turkey	33	48	81	1·7
Italy	22	54	76	1·6
Denmark	36	17	53	1·1
China and Japan	69	57	126	2·7
Egypt	61	22	83	1·8
Brazil	37	46	83	1·8
River Plate	14	46	60	1·2
Chili	19	15	34	0·7
Portugal	21	17	38	0·8

South Africa	38	39	77	1·6
Other Colonies	77	75	152	3·3
British Colonies	636	606	1242	26·4
Grand Total	2710	2025	4735	100·0

Shipping.—The merchant shipping of the British empire, colonies included, showed as follows:

Year.	Vessels	Tons.	Sailors.	Tons per Vessel.	Tons per Sailor.	Reign.
1588	470	37,400	..	80	..	Elizabeth.
1610	910	83,000	.	90	..	James I.
1666	1,320	120,000	..	90	..	Charles II.
1688	2,620	210,000	.	80	..	James II.
1702	3,260	261,000	.	80	.	Anne.
1760	5,730	487,000	.	85	.	George III.
1800	17,410	1,856,000	140,000	106	14	"
1810	23,703	2,426,000	162,000	102	15	"
1820	25,374	2,654,000	175,000	105	15	George IV.
1830	23,721	2,533,000	155,000	107	16	William IV.
1840	28,962	3,311,000	201,000	114	17	Victoria.
1850	34,288	4,233,000	239,000	124	18	"
1860	29,469	5,713,000	230,000	193	25	"
1870	32,920	7,150,000	261,000	216	27	"
1881	30,531	8,535,000	270,000	280	31	"
1887	28,212	8,936,000	280,000	320	32	"

The shipping of the United Kingdom, excluding colonial, has been as follows:

Year.	Vessels.	Tons.	Seamen.	Tons per Vessel.	Tons per Seamen.
1810	20,253	2,211,000	145,000	105	15
1830	19,174	2,202,000	131,000	114	17
1850	25,084	3,565,000	148,000	138	24
1870	26,367	5,691,000	196,000	215	29
1881	24,830	6,490,000	193,000	260	33
1887	22,136	7,340,000	203,000	334	36

The following table shows the ratio of British and Colonial tonnage in the world's shipping:

Year.	British and Colonial Flags.	Various Flags.	The World.	British Ratio.
	Tons.	Tons.	Tons.	
1820	2,654,000	3,900,000	6,554,000	40 per cent.
1842	3,311,000	6,200,000	9,511,000	35 "
1860	5,713,000	7,973,000	13,686,000	42 "
1870	7,150,000	8,426,000	15,576,000	46 "
1881	8,535,000	11,111,000	20,646,000	41 "
1887	8,936,000	12,966,000	21,902,000	42 "

In the foregoing tables no distinction is made between steam and sailing tonnage. A steamer, however, is found to make three ocean voyages or six short trips in the same time that a sailing vessel takes for one; we must therefore multiply steam tonnage at least by four, to arrive at the carrying-power. The following table makes this allowance, and under the head of Effective Carrying power it will be observed that the shipping of the British empire has multiplied six and a half times since 1840. Reference to American statistics shows that in the same interval the sea-going shipping of the United States increased in nominal tonnage only 200,000 tons, or 25 per cent.

Year.	Steam (nominal tonnage).		Sailing (nominal tonnage).		Effective Carrying power.	
	British.	Other Flags.	British.	Other Flags.	British.	Other Flags.
1840	95,000	21,000	3,216,000	6,180,000	3,596,000	6,264,000
1850	188,000	204,000	4,045,000	6,800,000	4,797,000	7,616,000
1860	502,000	318,000	5,211,000	7,655,000	7,219,000	8,927,000
1870	1,203,000	715,000	5,947,000	7,711,000	10,759,000	10,571,000
1881	3,105,000	2,539,000	5,430,000	9,572,000	17,850,000	19,728,000
1887	4,355,000	3,877,000	4,581,000	9,089,000	22,005,000	24,515,000

The carrying-power of the British merchant navy (including colonial) in 1887 was 22,000,000 tons, or considerably more than the total carrying-power of the world (21,300,000 tons) in 1870, since which year the British merchant shipping has doubled. It is now almost equal to the total effective tonnage of all other nations in the aggregate. The above table gives the following result:

	Carrying power.			Ratio.		
	1840	1860	1887	1840	1860	1887
	Tons.	Tons.	Tons.			
British	3,596,000	7,219,000	22,005,000	36·5	44·6	47·3
Other flags	6,264,000	8,927,000	24,515,000	63·5	55·4	52·7
The world	9,860,000	16,146,000	46,520,000	100·0	100·0	100·0

In the above table British includes colonial shipping. If we compare the merchant shipping of the United Kingdom only with that of other flags we find:

Year 1887.	Nominal Tonnage.	Carrying-power. Tons.	Ratio.
United Kingdom	7,340,000	19,590,000	42·0
United States	4,130,000	8,300,000	17·8
Germany	1,285,000	2,640,000	5·7
Norway	1,524,000	1,860,000	4·0
Canada	1,078,000	1,310,000	2·8
Russia	1,025,000	1,395,000	3·0
France	993,000	2,495,000	5·4
Italy	946,000	1,380,000	3·0
Spain	594,000	1,040,000	2·2
Sweden	517,000	890,000	1·9
Austria	349,000	770,000	1·6
Holland	286,000	610,000	1·3
Denmark	274,000	550,000	1·2
Austria	262,000	530,000	1·2
Greece	262,000	370,000	0·8
South America	75,000	490,000	1·0
Other Countries	785,000	1,720,000	3·8
The world	21,902,000	46,520,000	100·0

WEALTH.—Comparing Porter's table for 1840 with the estimates for 1860 and 1887, we find as follows, in million pounds sterling:

	1840	1860	1887
Railways	21	348	831
Houses	770	1164	2640
Furniture	385	582	1320
Lands	1680	1748	1560
Cattle, &c.	280	350	414
Shipping	23	44	130
Merchandise	70	150	321
Bullion	61	105	143
Sundries	810	827	1869
Total	4100	5368	9228

In the above table land in 1887 is put down at 1560 millions, whereas the official valuation at thirty years' purchase, as already shown under the item agriculture, is 1873 millions; but it is generally admitted that the official valuation is twenty per cent. over the real value.

The increase of wealth from 1840 to 1887 was 124 per cent., or three times greater than that of population. The annual accumulation averaged 64 millions sterling between 1840 and 1860, and 143 millions between the latter year and 1887. Wilson estimated the accumulation in 1840–45 at 60 millions yearly; Giffen, in 1880, at 150 millions. *Houses* constitute the largest item of public wealth—viz. 2640 millions sterling, the value being taken at twenty times the assessed annual rental. In this item alone we see an increase of 1870 millions since 1840, the number of new houses built between that year and 1880 being 2,218,000—say 55,000 yearly. It is probable that new houses represent only one-third of the increase of value, as the old ones (4,430,000) have likewise risen. Allowing for houses built since 1880, the number and value would be approximately thus:

	No.	Value, millions £s.	Per house £
Built before 1840	4,400,000	1730	393
Since 1840	2,700,000	910	340
Total in 1889	7,100,000	2640	372

The value of house-property per inhabitant varies in the three kingdoms:

	£ per inhab.		£ per inhab.
England	77	London	176
Scotland	62	Liverpool	114
Ireland	12	Glasgow	100
United Kingdom	71	Dublin	44

The value of house-property for the whole United Kingdom in 1840 was only £30 per inhabitant.

Furniture, according to insurance agents, averages half the value of houses; this item includes, moreover, pictures, clothing, jewelry, and carriages.

Lands. The value under this head has been explained already under Agricultural Statistics.

Railways are the fourth item of national wealth, the above statement of capital employed being from official returns. Since 1860 nearly 20 millions yearly have been thus invested in the three kingdoms, of course excluding similar investments abroad, which are comprised under Sundries.

Shipping.—The United Kingdom has 22,200 vessels, aggregate 7,400,000 tons, which, at the medium valuation of £17, 10s. per ton, makes 130 millions sterling. Over 3 millions yearly go into new merchant-vessels built in the three kingdoms.

Merchandise. We assume six months' imports and exports to represent at each of the above dates the value of merchandise on hand. It is probably under the reality.

Sundries were estimated in 1887 as follows :

	Million £s.
Canals, docks, dockyards, and navy	115
Gas, water-works, telegraphs	178
Colonial loans and railways	432
Australian mortgages	330
Foreign stocks	814
Total	1869

The amount of British capital in foreign stocks is variously estimated.

Bullion.—This is not properly wealth, but a token of it. However, in deference to vulgar prejudice, we include the estimated amount of gold and silver at different dates.

According to the Probate returns for 1881-85 the wealth held by the inhabitants of the United Kingdom would then have been only 8200 millions sterling. It must, however, be observed that estates under £100 escape the Probate Court, and many large estates are under-valued in proving succession; also, that the royal navy, dockyards, prisons, lighthouses, high-roads, &c. have to be added to the Probate estimates, which will bring us up to the total of 9228, as first stated.

RELIGION.—The census takes no note of religion except in Ireland, but the ratios of marriages in the different churches enable us to form a close estimate of the adherents to the various creeds in England and Scotland. On the basis of the census of 1881 the figures would stand thus :

	Numbers.			Percentage.			
	England.	Scotland.	Ireland.	England.	Scotland.	Ireland.	United Kingdom.
Church of England	18,798,000	99,000	636,000	72·3	2·7	12·3	55·8
Roman Catholic	1,066,000	318,000	3,952,000	4·1	8·6	77·1	15·2
Presbyterian	114,000	2,997,000	486,000	0·4	81·0	9·4	10·3
Methodist, &c.	5,990,000	281,000	48,000	23·2	7·7	0·9	18·7
Total	25,968,000	3,695,000	5,122,000	100·0	100·0	100·0	100·0

The Established Church, before the disestablishment in Ireland in 1869, comprised the following livings :

Nominated by	England.	Ireland.	Total.
Crown	952	131	1,083
Noblemen	5,096	340	5,436
Bishops, &c.	4,694	924	5,618
Total	10,742	1395	12,137

A report, published in 1880, on the income of the Established Church in England and Wales, was as follows :

Tithes	£4,054,000
Committee grants	776,000
Other sources	973,000
Total	£5,803,000

The above, however, included £962,000 of tithes that go to laymen, the real Church income being £4,841,000, distributed thus :

Clergy.	No.	Income.	Per Head.
Bishops	33	£168,000	£5100
Canons	166	240,000	1440
Rectors	11,780	3,830,000	330
Curates	5,050	603,000	120
Total	17,029	4,841,000	

The above does not include the 'offertory,' which has been found to range from £100 to £240 per annum in each church, and is estimated to sum up £2,200,000 yearly, at £120 per church. The Ecclesiastical Report for 1880 shows that in forty years the commissioners have expended 22½ millions in creating new endowments to an annual value of £746,000 in aid of 4700 distressed parishes —say £160 each. The commissioners distribute about £700,000 a year in creating new benefices, to an average amount of £23,000 per annum. Balance still in hand, £8,200,000. The above tables do not include collegiate endowments, worth £550,000 a year. Total clergy of Church of England 19,000, including 2000 schoolmasters. The Church of England has, moreover, 232 clergymen in Scotland, 820 in Ireland, and 2700 in colonies and foreign countries, making a grand total of 22,752.

The number of churches of all persuasions in England and Wales in 1883 was as follows :

Church of England	14,573
Methodist	11,514
Independent	2,603
Baptist	2,243
Calvinist	895
Roman Catholic	824
Quaker	375
Presbyterian	291
Jewish	60
Various	2,628
Total	35,916

In the above are not included 364 Roman Catholic chapels attached to religious houses, possessing no marriage license.

The condition of the Anglican Church in Ireland in 1880 was as follows :

Number of clergy	820
Number of laity	635,100
Endowment	£130,000
Donations	118,000
Total income	248,000
Endowed capital	3,260,000

There are twelve bishops, who receive £41,500 per annum—average £3600 each. In November 1880 the residue of property formerly belonging to the Anglican Church in Ireland was valued at 12 millions, producing a revenue of £574,000, to be devoted to purposes of general utility or beneficence.

The condition of the Roman Catholic Church in the British empire in 1882 was as follows :

	Bishops.	Priests.	Churches.	Laity.
England	15	2112	1188	1,066,000
Scotland	6	366	295	318,000
Ireland	28	3290	2760	3,952,000
Canada	24	1210	1050	2,150,000
Australia	16	376	787	584,000
India	22	1179	700	1,318,000
Other colonies	20	315	240	466,000
Total	131	8788	7020	9,854,000

The average income in the United Kingdom is £400 for a bishop, and £80 for a priest. In India it is £260 per bishop, and £36 per priest. In Canada and Australia it is higher than in England.

There are 51,000 Jews in the United Kingdom.

MANUFACTURES.—M'Pherson's table of British manufactures in 1782 compares with the estimates for 1882 (United Kingdom) as follows :

	1882		Per cent.	
			1782.	1882
Cotton goods	£260,000	£95,200,000	1·7	11·6
Woollen "	16,800,000	46,400,000	29·5	5·5
Linen "	1,750,000	11,770,000	3·1	1·4
Silk "	3,250,000	7,240,000	5·9	0·9
Leather	10,500,000	34,050,000	18·4	4·2
Iron and steel	12,100,000	127,000,000	21·4	15·4
Sundries	11,200,000	496,670,000	20·0	61·0
Total.....	£56,660,000	£818,300,000	100·0	100·0

The growth of the principal manufactures is shown as follows—value in million pounds sterling:

	1850.	1859	1869	1870	1881
Cottons	31	43	78	94	95
Woollens	23	29	38	55	46
Linen, &c.	9	17	17	18	21
Silks	8	10	18	16	7
Sundries	7	10	17	22	26
Textiles	78	109	168	215	195
Hardware	31	42	65	82	127
Textiles and Hardware	109	151	233	297	322

The preceding tables were prepared by Mr Mulhall from the materials of his *Dictionary of Statistics* (enlarged edition, 1891).

One rather unsatisfactory aspect of British manufacture in recent years has been the extent to which German goods have superseded, both in the United Kingdom and abroad, those of British make. The facts are thus summed up in E. G. Williams's *Made in Germany* (1896). While in twenty three years our population has increased by over 7,000,000, the declared value of our exports has fallen by over £30,000,000 a year. In 1883–93, while British exports were declining, the value of German manufactured goods imported into this country increased by £5,000,000 a year. In the same years, 1883–93, our imports of manufactured goods increased by £30,000,000, while the total value of our exports declined by £22,000,000. In iron and steel and in textiles, German goods are superseding British goods in the United States, some British colonies, and many markets where British commerce was formerly supreme.

POPULATION.—The following table shows the population of the United Kingdom at various dates since the first census that of 1801, in which Wales is given along with England. The counties, with their areas (in acres) and populations, are given for each of the main divisions of the empire under ENGLAND, SCOTLAND, IRELAND, and under their own heads.

	Area in acres.	1801.	1841.	1891.
England	40,823	8,892,536	15,002,443	27,483,490
Wales	7,363		911,705	1,519,035
Scotland	29,820	1,608,420	2,620,184	4,025,627
Ireland	32,574	5,395,456	8,196,597	1,704,750
Isle of Man	220		47,975	55,608
Channel Islands	75		76,065	92,234
Army, Navy, &c.			292,954	224,211
Total, Unit. Kingd.	120,832		27,057,923	38,104,175

At the census of 1881 the population was 35,241,482; in 1895 it was calculated at 39,134,166. In 1890–91 (not to mention those in the colonies, &c.) there were 3,122,911 natives of the United Kingdom in the United States, 39,687 in France, and 15,534 in Germany. In 1891 there were in England and Wales 282,271 natives of Scotland (253,528 in 1881), 458,315 natives of Ireland (562,374 in 1881), and 198,113 natives of foreign states, 50,599 (as against 37,301 in 1881) being Germans, 20,797 (as against 14,596) French, and 19,740 (as against 17,767) American citizens.

COLONIES.—The British colonial empire comprises some fifty distinct governments, and, including India, extends over nearly 10 millions of square miles—more than eighty times the area of the mother-country, or one-sixth of the habitable land-surface of the globe. The colonies and dependencies have a population of near 250½ millions as compared with the 40 millions in the mother-country. Of this, nearly 10,000,000 square miles belong to the nine self-governing colonies, with a population of over 10,000,000.

The following table shows the area and population of the colonies and dependencies of the empire. The populations are given according to the census of 1891 or later official estimates:

	Area in sq. miles.	Population.
India (British)	868,314	221,172,952
Straits Settlements	1,472	512,342
Ceylon	25,365	3,008,466
Mauritius	713	371,656
Labuan and British Borneo	30,000	175,853
Hong kong	30·5	221,441
Australia	2,944,628	2,051,003
Tasmania	26,215	146,667
New Zealand	104,458	626,658
Fiji	7,740	121,180
Falkland Isles	6,500	1,789
Natal	18,750	543,913
Cape of Good Hope	213,917	1,527,224
St Helena	47	4,116
Lagos	1,060	100,000
Gold Coast	29,401	1,475,882
Sierra Leone	3,000	180,000
Gambia	69	14,266
Canada	3,466,542	4,891,264
Newfoundland	42,000	202,040
Bermudas	19	15,319
Honduras	6,400	31,371
Bahamas	4,466	47,565
Turk's Islands	169	4,745
Jamaica	4,193	639,491
Windward Islands	784	140,777
Leeward Islands	666	127,723
Trinidad	1,754	208,068
British Guiana	109,000	278,295
Gibraltar	1	20,050
Malta	119	168,105
British New Guinea	90,000	350,000

The above figures do not include the tendatory states of India (595,167 miles: pop. (1891) 66,050,479), Nigeria, the Transvaal and Orange River Colonies, or Egypt and the Egyptian Soudan. Innumerable other subjects bearing on the resources, history, administration, &c. of the United Kingdom will be found under such heads as:

Agriculture.	England, Church of.	Parish.

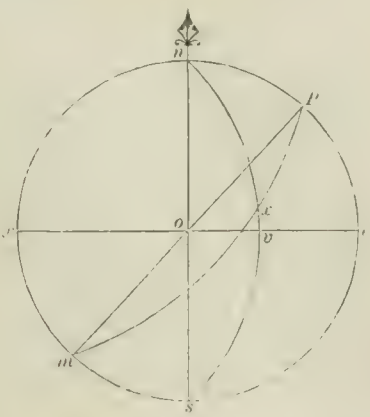
Great Circle or **Tangent Sailing.** In order to have a clear idea of the advantages of great circle sailing it is necessary to remember that the shortest distance between two places on the earth's surface is along an arc of a great circle (see SPHERE); for instance, the shortest distance between two places in the same latitude is not along the parallel of latitude, but along an arc of a circle whose plane would pass through the two places and the centre of the earth. The object, then, of great circle sailing is to determine what the course of a ship must be in order that it may coincide with a great circle of the earth, and thus render the distance sailed over the least possible. This problem may be solved in various ways. The handiest practical solution is to stretch a string over a terrestrial globe quite tight between the ports of departure and arrival. The string will lie on the great circle required. A few spots on the track of the string should be transferred to the ordinary navigating (i.e. Mercator's) chart, a free curve should be drawn through these transferred spots, and the ship should be kept as close to that curve as possible. The solution by computation is simply the calculation of sides and angles in a spherical triangle. The method by computation will be understood from the accompanying diagram, where *ns* are the poles of the



earth, *ev* the equator: *nmse* represents a meridian which passes through the place *p*, *nxvs* another meridian through the place *x*, and *pxm* a portion of a great circle; let *p* be the place sailed *from*, and *x* the place sailed *to*, then *px* is the great circle track, and it is required to determine the length of *px* (called the distance), and the angles *npx*, *nxp*, which are equal to the first and last true courses. To determine these we have three things given: *nx*, the co-latitude of *x*; *np*, the co-latitude of *p*; and the angle *xnp*, which, measured along *ve*, gives the difference of longitude. The problem thus becomes a simple case of spherical trigonometry, the way of solving which will be found in any of the ordinary treatises on the subject of Spherical Trigonometry.

Next, several longitudes on the route, say at 5 intervals, are chosen, and the co-latitudes of the spots on the great circle which correspond to these assumed longitudes are calculated. The latitude and longitude of these spots on the great circle being now obtained, the courses and distances from one to the other in succession can be found by the ordinary processes of navigation. The work is somewhat shortened by finding that particular spot on the entire great circle which lies farthest from the equator. It is called the vertex, and is easily found by the property that the meridian running through it is at right angles to the great circle at that spot. To avoid these, or some of these somewhat troublesome calculations, charts have been constructed on projections different from that of Mercator. On one of these, called the Gnomonic Projection, all the great circles are straight lines; on another, all the great circles are true circles. It has also been suggested that the ports of departure and arrival being given, and the *vertex* (described above) having been found, and all three having been marked on a Mercator's chart, a true circle drawn through these three spots will be near enough to the great circle for practical purposes. A modification of this approximate method is useful in the run between the Cape of Good Hope and Australia, on which the great circle route goes too far into the southern ice-region. If a spot of highest safe south latitude be here substituted for the latitude of the vertex, a circle drawn through the places of departure, of arrival, and of the substituted safe vertex will give what is called a *composite* great circle.

From the theory of great circle sailing the following most prominent features are at once deduced: *A ship sailing on a great circle makes direct for her port, and crosses the meridians at an angle which is always varying*, whereas, by other sailings, *the ship crosses all meridians at the same angle*, or, in nautical phrase, *her head is kept on the same point of the compass, and she never steers for the port direct till it is in sight, except in the two cases where the ordinary track lies* (1) *on a meridian*, or (2) *on the equator*. As Mercator's Chart (see MAP) is the one used by navigators, and on it the course by the ordinary sailings is laid down as a straight line, it follows, from the previous observations, that the great circle track must be represented by a curve, and a little consideration will show that the latter must always lie in a higher latitude than the former. If the track is in the northern hemisphere it trends towards the north pole; if in the southern hemisphere it trends towards the south pole. This explains how a curve-line on the Mercator's chart represents a shorter track between two places than a straight line does; for the difference of latitude is the same for both tracks, and the great circle has the advantage of the shorter degrees of longitude measured on the higher circles of latitude. Consequently, the higher the latitude is the more do the tracks differ, especially if the two places are nearly on the same parallel. The *point of maximum separation*, as it may be called, is that point in the great circle which is farthest from the rhumb-line on Mercator's chart. Since the errors of dead reckoning, or even of dead reckoning

supplemented by astronomical observation, prevent a ship from being kept for any length of time with certainty on a prescribed track, and thus may necessitate the calculation from time to time of a new path, in practice the accurate projection of a great circle track on the chart would be a waste of time. Some ignorantly object to great circle sailing on the ground that, on account of constant change of the course steered, a ship cannot be kept with absolute precision on the correct great circle track. But, in fact, all that is required of a navigator is to sail as near to his great circle track as convenient; and each separate course will be approximately a tangent to his track, and the shorter these tangents are made the more will the length of a voyage be diminished.

Great Eastern. This great ship, the largest piece of marine architecture ever put together, was planned (1852) by Brunel and Scott Russell at the instance of the Eastern Steam-navigation Company, a vessel being wanted for the route to Australia round the Cape which could carry enough coal for the voyage out and home, and have besides space for a large number of passengers and cargo. The scheme was for a ship that would accommodate 1000 passengers, 5000 tons of goods, and 15,000 tons of coal. As at first arranged for, the measurements were: length, 680 feet between perpendiculars, or 692 feet upper deck; breadth, 83 feet, or 118 over paddle-boxes; height of hull, 60 feet, or 70 to top of bulwarks. Ten partitions of plate crosswise of the ship divided the interior into 11 watertight compartments, further subdivided by longitudinal partitions. The propelling power comprised both paddle and screw. The 4 paddle-engines had 4 boilers; the 4 screw-engines had 6 boilers. The smoke from the furnaces ascended 5 funnels, 100 feet high by 6 in diameter. Setting aside the nominal power, all the 8 engines at full force were estimated to work up to 11,000 horse-power. There were 6 masts, 5 of them iron. The vast wall-sided compartments of the ship had facilities for conversion into cabins for 800 saloon passengers, 2000 second-class, 1200 third-class, and 400 officers and crew; or 5000 might have been accommodated in all if emigrants or troops. The height of the 'tween decks was 13 feet. Such were the plans for the mighty ship, which were never fully carried out in all their details, owing to numerous alterations and refittings.

During 1854–57 the operations proceeded at Millwall, in spite of frequent and heavy financial difficulties. By November 1857 the ship had advanced to the launching condition; but it required various attempts, between November 3, 1857, and January 31, 1858, and an expenditure of £60,000, to effect the launching. During 1858 and 1859 the works continued as fast as the company could supply money; and altogether the vessel was estimated to have cost £732,000. Uncertain how far the original intention of a trade to and from Australia could be realised, the directors determined on a trial trip across the Atlantic. It was a disaster. The ship left the Thames, September 8, 1859; an explosion of steam-pipes took place off Hastings; seven persons were killed and several wounded; and the voyage abruptly came to an end at Portland. The ship started again on June 17, 1860, from Southampton, crossed the Atlantic in eleven days, and reached New York on the 28th. During the remainder of 1860 and the greater part of 1861 she made many voyages to and fro, including the conveyance of Foot Guards to Canada, losing money by the insufficiency of the receipts to meet the current expenses, and constantly requiring repairs. For the arrangement and services of the ship in 1865 and 1866 in paying out the Atlantic cable, see ATLANTIC TELEGRAPH. In 1867 she was chartered to bring passengers from New York to Havre in connection with the Paris International Exhibition, but the scheme proved a failure. From 1869 onwards the *Great Eastern* successfully laid some of the most important telegraph cables—across the Atlantic, in the Mediterranean, Red Sea, &c. After acting as a coal-hulk at Gibraltar in 1884, the gigantic vessel was sold in London by auction for £26,200. Finally, after having been used for a time as a 'show' ship, she was sold by auction at Liverpool in November 1888, to be broken up, the five days' auction fetching £58,000.

Great Fish River, (1) in Cape Colony, rises in the Sneeuwberg Mountains, and, after a generally south-easterly course of 230 miles, enters the Indian Ocean in 33° 25′ S. lat. and 27° E. long. The Midland Railway which connects Port Elizabeth and Port Alfred with Kimberley skirts part of the river; there is an iron bridge at Cradock, and Fish River Station is 207 miles from Port Elizabeth.—(2) Great Fish River, or Back's River, in North America, enters an inlet of the Arctic Ocean in 95° W. long., after passing through Lake Pelly. Sir George Back (q.v.) traced its course to the ocean.

Great Grimsby. See GRIMSBY.

Great Kanawha (pronounced *Kanaw'wa*), an affluent of the Ohio River, is called New River in the upper part of its course, and rises in the Blue Ridge of North Carolina. It has a course of 450 miles, and is navigable to a fall 30 miles above Charleston, and about 100 miles from its mouth.

Great Marlow. See MARLOW.

Greatrakes, VALENTINE (sometimes called *Greatorex* and *Greatarick*), the 'touch doctor,' was born at Affane, near Lismore, in County Waterford, 14th February 1629. During the troubles of the Rebellion his mother fled in 1641 to England, and settled in Devonshire. From 1649 till 1656 he served as an officer in the Parliamentary army, and from 1656 till the Restoration he acted as a magistrate in his native place. About 1661 he began 'touching' for the king's evil, in obedience, he said, to a divine impulse, and ere long he touched or 'stroked' for ague and for all manner of disease. He was summoned to the king at Whitehall; multitudes flocked to him, and his cures were witnessed and attested by men so eminent as Robert Boyle, Ralph Cudworth, and Henry More. This predecessor of Mesmer did not profess to be always successful; but his claims provoked much controversy, and in 1666 he published in his own defence his *Brief Account* of himself and his cures. He died at Affane, 28th November 1683.

Great Salt Lake, in Utah, stretches along the western base of the Wahsatch Mountains, about 4200 feet above the sea, forming a principal drainage centre of the Great Basin (q.v.). Well-marked shore-lines on the mountains around, reaching 1000 feet higher than the present level, show that the lake had formerly a vastly greater extent; this prehistoric sea has been named Lake Bonneville. Great Salt Lake is over 80 miles long and from 20 to 32 broad, but for the most part exceedingly shallow. It contains several islands, the largest, Antelope Island, about 18 miles long. Its tributaries are the Bear, Ogden, Jordan, and Weber, the Jordan bringing the fresh waters of Lake Utah; but Great Salt Lake has no outlet save evaporation, and its clear water consequently holds at all times a considerable quantity of saline matter in solution; in 1850 the proportion was 22·4 per cent., in 1869 it was only 14·8. Between these dates the annual tribute exceeded the evaporation, and the area of the lake increased from 1700 to 2360 sq. m.; more recently, it has again been slowly receding. Several species of insects and a brine-shrimp have been found in its waters, but no fishes; large flocks

of water-fowls frequent the shores. The first mention of Great Salt Lake was by the Franciscan friar Escalante in 1776, but it was first explored and described in 1843 by Fremont; for the value of Baron La Hontan's fables, see H. H. Bancroft's *Utah* (San Francisco, 1889). A thorough survey was made in 1849–50 by Captain Howard Stansbury, U.S.A. See SALT LAKE CITY, and UTAH.

Great Seal of England. See SEAL.

Great Slave Lake lies in the Canadian North-west Territory (62° N. lat.). Its greatest length is about 300 miles, and its greatest breadth 50 miles. By the Slave River it receives the surplus waters of Lake Athabasca; and it discharges by the Mackenzie River into the Arctic Ocean. See ATHABASCA.

Great Wall of China. See CHINA, Vol. III. p. 185.

Greaves. See ARMOUR.

Grebe (*Podiceps*), a genus of diving birds (Pygopodes), usually frequenting rivers and fresh-water lakes, and visiting the sea only when migrating or in winter. The foot of the grebe is broad and flattened; the toes lobed and bearing separate membranes united only at the base; the wings are short and rounded; and there is virtually no tail. The legs are placed so far back that the bird stands erect like the penguins. Its movements on land are ungainly in the extreme, but it swims gracefully, and is the most expert of divers, not using its wings, but propelling itself on its downward career solely by the aid of its paddle-like feet. The grebe seldom leaves the water, and can even swim under the surface for a considerable distance, threading its way with wonderful expertness among the stalks and leaves of aquatic plants. A floating nest is built of leaves and twigs and moored to reeds or grasses. The eggs are covered with a chalky incrustation, and are so wide in the middle as to look almost biconical. The mother-bird, before leaving the nest, scratches the weeds over them with her feet, so that the whole looks like a tangled mass of rubbish. She is careful of her young, carrying them on her back, and even diving with one under her wing. The grebe feeds chiefly on crustaceans, frogs, and small fishes, partly, however, on vegetable food. The plumage varies at different seasons.

The Great Crested Grebe (*P. cristatus*) is found

Great Crested Grebe (*Podiceps cristatus*) and Nest.

all the year round on inland lakes in England and Ireland, more rarely in Scotland, and at the sea-coast in winter when driven by frost from the lakes. The adult male is 22 inches in length, and is very conspicuous in flying because of the glossy whiteness of the plumage on the ventral surface; the female is smaller and has a less developed crest. The best-known British species is the Little Grebe or Dabchick (*P. fluviatilis*), one of our most beautiful river-birds, which is widely distributed throughout England and Ireland, and is also found in Scotland, where it breeds at an elevation of 2000 feet. In summer the head, neck, and upper parts are dark brown, the under parts grayish-white; in winter the colours are paler. Gould describes the young dabchicks as having 'delicate rose-coloured bills, harlequin-like markings, and rosy-white aprons.' The adult bird only reaches a length of 9 to 10 inches. The Red-necked Grebe (*P. griseigena*) and the Slavonian or Horned Grebe (*P. auritus*) visit our shores in autumn and winter, and the Black-necked or Eared Grebe (*P. nigricollis*) in spring and summer. An allied genus, Podilymbus, comprising two species, is confined to North and South America. The grebes are much sought after for their plumage, but their shyness and their great agility in diving and swimming under water render them extremely difficult to shoot. So easily alarmed are they that Mr Ruskin, in his somewhat revolutionary treatment of ornithological nomenclature, proposed to rename the genus Trepida. The skin of the grebes is made into muffs or cut into strips for trimmings, the beautiful, satiny plumage on the lower parts of the body of the Great Crested Grebe being in particular request for these purposes. See Howard Saunders, *Manual of British Birds;* and Ruskin, *Love's Meinie.*

Grecian Architecture. See GREEK ARCHITECTURE.

Greece is the easternmost of the three peninsulas projected southwards by Europe into the Mediterranean; and being for the most part limestone, is a continuation of the great mountain-system which stretches from Spain to Syria, encloses the basin of the Mediterranean with precipitous edges, and shuts off the three peninsulas from the continent. In no other country has the geography more influenced the history than in Greece; and the tendencies of this influence are expressed on the one hand in Wordsworth's lines:

> Two Voices are there; one is of the Sea,
> One of the Mountains; each a mighty Voice:
> In both from age to age thou didst rejoice,
> They were thy chosen music, Liberty!

and on the other in Hegel's dictum: 'Mountains alone divide, seas unite.' Thus, as the west coast of Greece is mountainous and harbourless, whilst the east is full of bays, gulfs, and havens, Greece turned her back on Italy, and was brought into intimate communication with Asia Minor. The easternmost of the three basins into which the Mediterranean is divided became a Greek lake. The greatest factor in Greek unity was the Ægean Sea, for it united the Greeks of the mother-country with the Greeks of the isles and of the coast of Asia Minor. At the same time, as the coast is the first part of a new country to become civilised, and Greece has relatively a longer coast-line than any other country in Europe, just as Europe has more coast than any other quarter of the globe, the history of European civilisation begins with Greece. On the other hand, the spirit of liberty, which nerved the Greeks to resist the Persians, and so save the civilisation of the world, was due to the mountains of Greece; but the divisions between the Greeks themselves were also due to the mountains, which divided the land into cantons incapable of effectual combination against the Macedonian invader who conquered them all.

Let us then begin with the mountains, and, so to speak, articulate the skeleton of Greece. The range which in the north cuts off the peninsula from

the continent of Europe is an extension of the Balkans. From it run chains from north to south, or rather from north north west to south-south-east, which form the skeleton of Greece. The most important of these is the range which forms the backbone of the country, separating first Illyria on the west from Macedonia on the east, and then Epirus on the west from Thessaly on the east. Thus the western boundary of Thessaly is formed by Pindus (7111 feet), the main offshoot of the Balkans. The eastern boundary is also marked not only by the sea, but by important mountains derived from the Balkan system. These are Olympus (9750 feet), Ossa, Mavrovuni, and Pelion. Returning to Pindus, we find that its tendency to the east becomes now more pronounced, and a branch of it, under the name of Othrys, starting from the mighty Tymphrestus (mod. *Velukhi*, 7606 feet), forms the south boundary of Thessaly. It then is continued in the celebrated mountains Parnassus (8036 feet) and Helicon, forms the land of Attica, and reappears as the islands of Ceos, Cythnos, Seriphos, and Siphnos. The subsequent course of that branch of the Balkans which we have mentioned as marking in part the eastern boundary of Thessaly is equally interesting, for it forms first the island of Eubœa, and then the isles of Andros, Tenos, Myconus, Naxos, and Amorgos. The Peloponnese, 'the island of Pelops,' or by its modern name the Morea, is connected with northern Greece merely by the narrow isthmus of Corinth, and is separated from it by the long if narrow Gulf of Corinth on the west and the Saronic Gulf on the east. The commercial supremacy of ancient Corinth, standing as it did on 'two bright havens,' and on the road from Peloponnese to the mainland, was due to its position: and we need only add, in further explanation, that all the great trade routes from the Ural Mountains, the Black Sea, and Asia Minor to Sicily, Marseilles, and the West converged at Corinth.

The Peloponnese has a mountain-system which is derived, like the others of Greece, from the Balkans, runs parallel to and west of Pindus, and shows itself in the Acroceraunian Mountains and in Araecynthus. From the central group of mountains which surround Arcadia, and are highest on its north frontiers between Arcadia and Achaia, e.g. Cyllene (*Zyria*), Aroania (*Chelmos*, 7724 feet), and Erymanthus (*Olonos*) run two important chains, in the same north-north-west to south-south-east direction which we observed in the Pindus. Of these, the westernmost is the Taygetus (*Hagios Elias*, 7901 feet), the highest peak in the Peloponnese, which, after dividing Laconia on the east from Messenia on the west, ends in the promontory of Tænarum; while the eastern one separates Arcadia from Argolis, runs down Laconia under the name of Parnon (*Malevo*), and makes its last appearance as the island of Cythera. And here we may complete our account of the isles of Greece by adding that the Ionian Isles, Corcyra, Cephallenia, Leucas, and Zacynthus, off the west coast, follow the same north-north-west to south-south-east direction as the mountain-chains of the Peloponnese and the mainland.

The *rivers* of Greece are unimportant. They flow generally, both in the Peloponnese and the mainland, south or west. In the latter the four principal rivers have their source on Mount Lakmon, the starting-point of Pindus, and flow, the Aoos (*Viosa*) into the Adriatic, the Achelous (*Aspropotamos*) to the Gulf of Patræ, the Peneus (*Salambrias*) and Haliacmon into the Thermaic Gulf. The principal rivers of the Peloponnese rise near the north of Taygetus: the Alpheus (*Ruphia*) flows west, the Eurotas south.

People.—The ancient Greeks were a branch of that family which includes most European peoples, and also the Persians and the Hindus, and is variously called Indo-Germanic, Indo-European, and Aryan. The Indo-European family is not an ethnological division of the human race, but a linguistic: the languages spoken by the various Indo-Europeans are descended from one and the same original language (now lost), but the peoples who speak it, indeed the people who spoke the original language, need not necessarily, though they may quite possibly, be all of the same descent, for one nation may, directly or indirectly, compel another to adopt its language. Whether the original Indo-European home was in Europe or in Asia is a matter still in dispute. What is less open to doubt is that it was from the north that the Greeks entered Greece, and that they were nomad tribes depending for subsistence mainly on their flocks, though they knew how in extremity to cultivate the ground in a primitive fashion. Metals they were hardly acquainted with; they were still in the Stone Age. As they moved southwards in separate tribes, the foremost tribes were impelled forward by the pressure of those behind; and even when the whole of the peninsula had been for some time filled and fully occupied, a fresh wave of immigrants might wash over the whole country, disturbing everything. Such a wave was the 'Return of the Heraclidæ,' or the 'Dorian Invasion.' The result was to drive emigrants on to and over the isles of Greece to plant Greek cities and Greek culture on the coasts of Asia Minor. At later times Sicily, the Black Sea, Libya, &c. were dotted with Greek colonies; and wherever Greeks were, there, to the Greek mind, was Hellas, which is thus an ethnological rather than a territorial term. As for the name of the Greeks, they called themselves *Hellenes*, a designation the origin of which is still unknown; the inhabitants of Italy called them *Græci*; the Orientals, *Ionians*; while in Homer they are called *Danaans* and *Achæans*.

The modern Greeks are by no means pure-bred descendants of the ancient Greeks. Indeed, it has been maintained by Fallmerayer that from the 7th century A.D. there have been no pure Greeks in the country, but only Slavs. It is, however, pretty certain that the 1¾ million of modern inhabitants are descendants of the three races that occupied the soil at the time of the Roman Conquest—viz. Greeks, Thracians (mod. Wallachians), and Illyrians (Albanians).

Language.—The Indo-European family of speech includes, in addition to Greek, the following branches: Hindu-Persian, Armenian, Albanian, Italian, Celtic, Teutonic, and Slavo-Baltic. Of these that with which Greek was supposed to have the most affinities was the other classical language, Latin; and the two peoples were accordingly supposed to have dwelt together after leaving the original home, and to have jointly gone through a Græco-Italian period. This view, however, is exposed to many difficulties: the inflections of the Latin verb are more closely connected with Celtic; the syntax of Greek bears more resemblance to that of Sanskrit; and while the vocabulary of Latin is more closely bound up with that of the Teutonic languages, the Greek coincides more frequently with the Hindu-Persian. The dialects into which the ancient language was divided may be grouped as follows: (1) Ionic and Attic; (2) Dorian (covering the Peloponnese and its colonies); (3) the North-western dialects (those of Phocis, Locris, Ætolia, Acarnania, and Epirus); (4) Æolian (Lesbos, North Thessaly, Bœotia); (5) Elis; (6) Arcadian and Cyprian; (7) Pamphylian.

The ancient dialects continued to be spoken at anyrate till the time of Tatian (*adv. Græc.* 171)—i.e. the end of the 2d century A.D. By 263 A.D.,

W & R CHAMBERS, LIMITED, LONDON & EDINBURGH

however, as appears from a letter of the Emperor Julian, and an anecdote told a few years later of Chrysostom, the common people were beginning to have a difficulty in understanding ancient Greek. Inflections then began to disappear, foreign words to debase the vocabulary, the quantity of syllables to be disregarded, Greek words to be mutilated in form and changed in meaning. None of these tendencies were new: they may be detected from the beginning of the life of the language, even in Homer. Nor are they peculiar to Greek. But the conditions were favourable to their development as they never had been before, and rarely have been elsewhere. Foremost amongst these developing conditions must be placed the fact that for centuries the language was not a nation's organ of speech, nor the expression of a national life. Attempts are being made at the present day to revert to the use of ancient Greek, 'correct' Greek (ἡ καθαρεύουσα or νεοελληνική or ἑλληνική), for literary purposes; but the spoken language (δημώδης or χυδαία) is too far decomposed to admit of a successful infusion of ancient forms, and not sufficiently advanced to throw off all connection with the ancient tongue.

Ancient Religion.—That the Greeks worshipped many gods, and those made in the image of man, needs not to be demonstrated. Let it be granted also for the purposes of this article that religion is not the same thing as Mysteries (q.v.), or Mythology (q.v. also), and that the reader may be referred to the special articles on the various Greek gods for their respective attributes and legends. The question at once arises: In what sense of the word could the Greeks have a religion? Their mythology taught them that the gods were deceitful and approved of deceit (Athene), were cowardly, even the god of war (Ares), were guilty of cannibalistic infanticide (Cronos), incest (Cronos and Rhea, Zeus and Hera), bestial amours (Zeus), and what was tantamount amongst immortals to parricide (Uranos, Cronos, and Zeus). And though Greeks did not spend all their days listening to these repulsive stories, they did every day perform a number of rites and ceremonies which were puerile, unmeaning, and absurd; while they showed the opinion they held of their gods by the faith which they had that they could buy their favour or buy off their disfavour by offerings. Nor can it be alleged that this is our way, not theirs, of regarding their myths and cults. From the time of Xenophanes to that of Euripides philosophers and poets did not weary of denouncing the immorality and bestiality of these myths. Plato protested that the current theory of offerings and sacrifice made religion a variety of higgling in the celestial market, a sort of political economy of the spiritual world. Aristophanes and the comedians of the old school could place a god in *propria persona* upon the stage to be derided for his cowardice, braggadocio, and gluttony. Under these circumstances, then, what sort of religion was it that the Greeks could have?

In the first place, whether it was that Zeus controlled the other gods, or that he as well as they was guided by fate or destiny or necessity, the universe was, the Greeks believed as well as we, ruled for some good end. In other words, they had faith; and—which enlists our sympathies—that faith was tried. They were not slow to observe that, though the good do often prosper and the wicked suffer in this world, the rule is far from absolute; and we find, e.g. in Theognis and Solon, that they could not reconcile this with their faith, but for all that they did not cease to believe. Again, whatever faith they put in the efficacy of sacrifice and rites and ceremonies, they also believed that a good life was that which was most acceptable in the sight of the gods. They certainly believed that wrong-doing provoked the displeasure of heaven, and Æschylus was led to discover that the sins of the father were visited on the children, while to Herodotus and the Greeks generally their gods seemed jealous gods. If it be asked how all this could be reconciled with a belief in their revolting myths, there are various answers: what was right for the gods might be not right for men, just as the schoolboy has no doubt that it is right for his father but not right for himself to smoke, sit up late, or the like; or the myths might be the invention of misguiding or misguided poets, or might mean something and were not to be interpreted literally.

Next, as to their conception of a future world. In the earliest (Homeric) times it could scarcely have been a potent religious factor; it is almost purely mythological. If a wrong-doer like Sisyphus or Tantalus is punished in Hades, merit can hardly be said to be rewarded: the ghost of Orion continues, like the Red man's spirit, to go hunting, but Achilles thinks the meanest life on earth preferable to being king of the shades below. But in course of time, when it became impossible to believe that the good were always rewarded and the bad punished in this world, and when even the theory that the sins of the father are visited on the children was found an inadequate explanation of the sufferings of the innocent, the belief in a system of future punishments and rewards grew in strength, and in Plato's time (*Rep.* 330 D. and 363) was firmly held by the average respectable Greek. On the whole then it seems probable that in Greece myth did not kill religion, and that it was not myth but religion which dominated the morality of Greece, as it also dominated Greek art, especially sculpture.

The Greeks, therefore, were not without religion. How then did it differ from modern systems? The more educated Greeks were, in many cases, monotheists, Zeus being supreme, and the other gods his angels; and the conception of the paternal love of God was not strange to them. The essential difference is that the Greeks were not taught their religion by authority, whether of revelation, the state, or a priesthood. They had no revealed book (Homer and Hesiod fixed the theogony indeed, but not the religion); they had no priests having authority, and as long as a Greek performed the rites prescribed by the state he might interpret them as he pleased. Thus, though on the one hand there was nothing to prevent a man becoming a practical monotheist, on the other, for want of organisation and authority, the many elements of good there were in the religion of the Greeks doubtless acted less potently than they might have acted. Let us remember, however, that had any dogmas been enforced, they might have been the wrong ones. Finally, it is in harmony with the Greek character generally that in Greece there was no devil.

In modern Greece the church is the Orthodox Greek Church, which is 'endowed' in that bishops and archbishops are paid by the state (the inferior clergy, however, by voluntary fees), and is 'established' in that the archbishops and bishops are nominated by the king, as is the Synod of Five which is supreme in the church; and that, except in purely spiritual matters, the synod is dependent on the government.

History.—The earliest fact in the history of Greece of which we can feel certain is the Dorian invasion, or as the mythical version of this undoubtedly historic fact terms it, 'the return of the Heraclidæ.' Its date can of course only be approximately conjectured, but we may take it that the changes in the ethnological map occasioned by the Dorian invasion took about a couple of centuries to effect, and were completed about 1000 B.C.

The Homeric poems relate events which the author or authors supposed to be prior to the Dorian invasion; but the supposed facts belong probably to the domain of myth, and the poems themselves were certainly composed after the Dorian invasion. Whether the remains discovered by Schliemann at Troy, Mycenæ, and Tiryns date from before or after the invasion is still a moot point. The balance of opinion is in favour of the earlier period, on the ground that nothing but such a political cataclysm as the invasion could sweep away so completely the very memory of the dynasties which erected the marvellous monuments that remain to us. But even if the earlier date be assigned to these remains we are still in complete ignorance as to the name and even the race of which they are the sole memorials. It was once the fashion to call everything dating from before the Dorian invasion Pelasgic, and imagine that thereby all was explained. The Pelasgi were a mysterious people about whom nothing was known, and conjectures were most divergent. Very frequently they were identified with the common ancestors of the Greeks and Italians. But a Græco-Italian period and people are now on the way to being discredited: and the Pelasgi, if we confine ourselves to facts, were an insignificant tribe of Greeks. Finally, we may dismiss the period antecedent to the Dorian invasion by noting that in it the Phœnicians were believed to have largely influenced Greek culture; but the extent of their influence is now universally admitted to have been exaggerated, and it is a question whether it must not be referred wholly to a later period.

Of the Dorian invasion itself, what we know is that the tribe which had occupied Epirus moved into the valley of the Peneus, and were henceforth known as Thessalians; that probably in consequence of this the Arnæans, who had occupied Thessaly, were forced forward into the basin of the Copais, where they are known to history as the Bœotians; while from Doris bands of warriors kept crossing the Corinthian Gulf, finding their way across Arcadia to the south and east of the Peloponnese, and there forming Dorian settlements. Possibly to the same period we may assign the occupation of Elis by the Ætolians. Attica lying out of the direct line of impact, which was from north to south, was unaffected by these movements, except that fugitive families, especially of the same Ionic race as the inhabitants of Attica, took refuge there. On the other hand, it is to this movement that the Dorian state, Sparta, which was to be the great and victorious rival of Athens, owed its origin, and indeed we may say its subsequent greatness. The constitution and the peculiar institutions which made the Spartans a nation of soldiers are indeed referred, rather by myth than tradition, to a great legislator, Lycurgus. But they are in truth partly Indo-European customs preserved more faithfully by Sparta than by other Greeks, and still more the outcome of the perpetual struggle for existence which for generations was waged by the handful of Spartans against the large numbers of the native inhabitants. The Dorians settled in Sparta were indeed but a garrison in the beginning; and, to the end, their national life was that of the camp. Amongst the other consequences of the Dorian invasion that which most calls for notice is that in the various districts affected by it the original inhabitants were reduced to slavery; some being like the Helots in Sparta, serfs attached to the soil and belonging to the state rather than to any individual owner, others like the Perioeci, in Sparta, enjoying personal freedom, local self-government though not political rights; and both being very different from the bought slaves (frequently or mostly foreign) who formed the foundation on which Athenian civilisation, for instance was based.

The effects of the Dorian invasion, however, were not confined to Greece proper; amongst them must be included the expansion of Hellas in the wider sense of the word, and the colonisation of the coasts of Asia Minor. Not all the original inhabitants of the districts invaded remained to be enslaved: many fled over seas, the Æolians to found the Æolian cities, the Ionians to plant the Ionic colonies south of the Æolian, while the Dorians found their way by Crete to the shores south of the Ionic colonies. Of the law that colonies are more rapid in their development than the mother-country, the most conspicuous example is afforded by the Greek colonies in Asia Minor. The seeds of literature, art, and philosophy were all sown and first nurtured in the colonies, though to come to maturity it was in many cases necessary that they should be transplanted to the mother-country. In political life and constitutional history the stages through which Greece proper went were anticipated in the colonies; the change by which monarchy was set aside by aristocracy did indeed perhaps take place about the same time at home and in the colonies—we have little evidence how it took place anywhere—but the change by which aristocratical government was overthrown and democracy established was incomparably more rapid in the colonies. A colony is not the place in which privilege flourishes; tradition is less potent and individual energy more certain of its reward than at home. It was in the colonies, the western not the eastern, that the custom which preceded law was first reduced to writing, and the sole right of expounding it withdrawn from the privileged classes. It was in the colonies also that tyranny was first invented. A Greek tyrant was usually an aristocrat who, under the pretence of relieving the misery of the people, acquired a power which he used for crushing his own class and the people alike beneath his own illegal, personal, and violent sway. As he acquired his power by force, so by force he maintained it, and so by force he lost it, generally in a very brief time; though we must not forget that Syracuse under the tyrant Gelo defeated the Carthaginian power, and under his successor, the magnificent Hiero, almost made Sicily one state.

The rapid, indeed the premature, development of the Greek cities in Asia Minor is testified to by nothing more clearly than by the large number of colonies which they, themselves colonies, founded. The settlements on the Black Sea—e.g. Sinope, Trapezus, Cyzicus—were their creation, as were those in the remotest west—e.g. Marseilles. Many colonies, however, were founded direct from home: the coasts of Macedonia and Thrace were colonised from Eubœa, and it was the Chalcidians of Eubœa who led the way in the colonisation of the west—e.g. in Italy, Cyme and Rhegium; in Sicily, Naxos. A notable mother of colonies too was Corinth: Corcyra, Leucas, Anactorium, Ambracia, Apollonia, and Syracuse were all sprung from Corinth, and themselves in their turn sent out colonies. Thus all three of the basins of which the Mediterranean consists passed out of the hands of the Phœnicians, who had hitherto monopolised them, into the hands of the Greeks, as a rule without bloodshed, for the Phœnicians were traders and loved not fighting. But eventually the Carthaginians made a stand, and in 532 B.C., in alliance with the Etruscans, defeated the Greeks off Corsica, and secured the safety of their possessions in Africa and of the few towns left them in Sicily. Great, however, as was the expansion of Hellas and her colonies, no Greek state ever possessed a colonial empire; the colonies could not and would not be governed from home.

The difficulties of communication and the Greek love of autonomy secured the independence of the colonies as far as the mother-states were concerned, but not as against neighbouring and foreign powers. Thus, the Asiatic Greeks fell an easy prey, first to the Lydian monarch Crœsus (560), and then to the Persian Cyrus, the conqueror of Crœsus (546). And thus the Persian empire was brought into the necessity of absorbing or endeavouring to absorb Greece in the same way as the Roman empire was compelled to annex Britain; in the one case Britain, in the other Greece, offered a refuge and a *point d'appui* to fugitives and instigators to revolt. In the one case Gaul, in the other the Asiatic colonies, would never cease struggling for independence as long as their kinsfolk across the sea were free. What the course of events was which raised up in Greece a power competent to repel the flood of barbarism which threatened to extinguish the art, literature, and philosophy of Greece, and therefore of the world, we must now briefly state.

The weakness of Greece in the face of an invader was that although the Greeks were no longer nomads but had reached the stage of city life, and although the bond of blood and kinship was being displaced by the tie of neighbourhood and territorial organisation, the numerous communities were subject to no central government. The state of things in Greece may be compared—reasonably, for it had its origin in similar circumstances—with that in England at the time of the so-called Heptarchy, except that there were many more than seven independent states in Greece, and scarcely any of them were as large as even a small English shire. Most of them were cities with but three or four miles of territory; only two succeeded in reaching the size of an English county. Those two were the greatest names in Greece, Attica and Sparta. By what process of coalescence (or *synoikismos*, as it is called) the various village-communities of Attica became united with Athens for the seat of government we know not. Nor can we do more here than say that before the Persian wars Attica had passed through several social and political and politico-economical crises; Solon's reforms remedied the latter, but his political measures did not prevent the institution of a tyranny, that of Pisistratus and his sons. The tyrants, however, were expelled, and the democracy of Athens placed on the path which it was to follow by Clisthenes.

Meanwhile in the Peloponnese Sparta was obtaining that position of supremacy which subsequently enabled the Greeks to offer resistance to the Persians with some show of unity. Not only did Laconia stand to Sparta somewhat in the same relation as Attica to Athens, but Sparta conquered the neighbouring territory of Messenia (after two desperate wars), and deprived Argos, hitherto the leading state in the Peloponnese, of the district between Parnon and the sea, and of Cythera. Here, however, Sparta's career of conquest and annexation was arrested by the sturdy and successful resistance of the small city of Tegea; and henceforth Sparta's policy was confederation, not annexation. The league of states which had followed Argos was broken up; Epidaurus, Phlius, Trœzene, Hermione, and even Ægina went over to Sparta. Elis had become bound by community of interest to Sparta in the Messenian wars; and Tegea and Arcadia having resisted annexation, submitted to confederation. Thus, in the Peloponnese at least, Sparta was the undoubted leader of the Greeks; and, outside the Peloponnese, Athens promptly set the example of acknowledging Sparta to be the proper leader of all Greece against the Persians. But in 490 B.C., when Datis and Artaphernes, at the command of Darius, led the first Persian expedition against Greece, it was Athens alone that withstood them, and single-handed won the glorious victory of Marathon, thanks to the genius of Miltiades and the valour of her sons. For a time the danger of invasion was averted, but only for a time. If, however, Xerxes, the successor of Darius, availed himself of the interval for enormous preparations, Athens, also under the keen-sighted guidance of a great statesman, Themistocles, was also preparing that navy which was to deal the final, fatal blow at Xerxes. The number of that monarch's troops we have no means of estimating; we may safely say it was the greatest army that ever took the field. The Greeks' first line of defence—the pass of Tempe—was given up because it could be turned. The second—Thermopylæ and Artemisium—was turned, and the famous band of Spartans were sacrificed by the hesitation and procrastination of the Spartan government. Then the Persians ravaged Attica and destroyed Athens, but not the Athenians. They had fled to the neighbouring island of Salamis, and there they defeated, thanks to Themistocles, the Persian fleet, and sent the Persian monarch home in flight (480 B.C.). Then, indeed, the Spartans made up their minds to join the Athenians in attacking the Persian commander who had been left behind in Greece with a large force. With his defeat at Platæa (479 B.C.) and the victorious attack made by the Greek fleet on the enemy in his own waters at Mycale (479 B.C.) the Persian wars came to an end, and the seeds of a far more fatal struggle, because internecine, were sown. That struggle was between Athens and Sparta.

The position of undisputed leadership which Sparta had enjoyed at the beginning of the Persian wars she had lost before the end of them. For this the main reason must be admitted to be that Sparta acted with disgraceful selfishness, Athens with glorious self-sacrifice, throughout. When, therefore, the Greeks of the islands formed a league—the Confederation of Delos—for defence against the Persians, it is not surprising that the foremost place in it was accorded to Athens. In course of time many members of the league preferred to pay monetary contributions rather than supply ships and men; Athens on the contrary was ever eager to provide both men and ships. Thus Athens came to have the power of the sword—and therefore of the purse—in the confederation, which now was practically constituted not of allies but subjects. Not content with the command of the sea she thus acquired, Athens by a series of victories and under the guidance of Pericles attained a position of commanding influence in continental Greece, which, however, only endured from 456 to 445. In spite, however, of the loss of influence occasioned to Athens by her defeat at Coronea (447), and in spite of the Thirty Years' Truce concluded in 445 between Athens and Sparta, in 432 Athens and Sparta, making a quarrel between Corinth and Corcyra their pretext, began their great duel, the Peloponnesian war. Sparta was by its constitution a predatory, Athens an industrial state. The Spartans were farmers, the Athenians merchants. Sparta's strength was on land, Athens' on sea. Sparta prided herself on the ignorance of her sons, Athens on being herself the instructress of Greece. Sparta represented and received the support of oligarchy; Athens, democracy. For thrice nine years, as the oracles prophesied, the war lasted. Its varied and tragic fortunes cannot here be traced. Suffice it to say that there were three things which brought about the defeat of Athens: the early death of her greatest statesman, Pericles; her attempt, magnificent and tragic, to conquer Sicily; and the Persian gold which Sparta was base enough to accept and use.

Thus the supremacy of Sparta (404–379) was established. But it was no sooner established than

a reaction set in against it. Sparta had proclaimed at the Peloponnesian war that her policy was to restore to the Greeks the freedom which the Athenians had robbed them of. True it is that Sparta broke up the confederacy of Delos; but she did not give freedom to Athens late subject allies. She merely displaced democratic by oligarchic governments, and placed in each town a Spartan harmost or governor, whose excesses and violence made Sparta loathed. At the same time it was not the interest of the Persian king to allow Athens to be entirely crushed, or any single state to have preponderating power in Greece. Thus an anti-Spartan coalition was formed; and in spite of the peace of Antalcidas (387), the terms of which were designed to prevent the formation of any more such confederations as that of Delos, in 378 Athens was enabled to form a new confederacy, and to carry on hostilities with Sparta. These hostilities were not decisive, but they allowed Thebes to unite all Boeotia into a single state, and by the genius of Pelopidas and Epaminondas, so to consolidate its power as to defeat Sparta at Leuctra (370), and establish a Theban supremacy. Sparta had to withdraw her harmosts from all cities; and everywhere the democrats in consequence came into power. Arcadia was made into one state with a new city, Megalopolis, at its head; and Messenia was made independent of Sparta. But Thebes was wholly unequal to the position which she aspired to occupy; Athens united with Sparta in resisting her, a great anti-Theban coalition was formed, and when Pelopidas fell at Cynoscephalæ (363) and Epaminondas at Mantinea (362) Thebes lost the only two men of genius she possessed, and with them all hope of maintaining the position she had attained.

Thus the village-communities with which Greek, like English history, begins had become city-states; but the Greeks travelled no further along the path of political coalescence or *synoikismos*. If the English did travel further through heptarchy to final unity, it was because in England 'war begat the king,' whereas in Greece monarchy (if indeed it ever existed) passed away before history begins; and the spirit of autonomy, begotten of republican rule, was centrifugal in tendency. Meanwhile in Macedonia, whose inhabitants, if not of Greek blood, were not distantly akin to Greeks, a kingdom was forming which was destined to impose on Greece, from without, the only unity it was capable of receiving. The steps by which Philip of Macedon made himself master of Greece were well marked and rapid. The first places to be absorbed by the expansion of Macedonia were the Greek colonies on the coasts of Thrace and Macedonia, in 357 Amphipolis and Pydna, in 356 Pangæum, in 353 Halonnesos, Abdera, Maroneia, Methone; and in 348 the fall of Olynthus and its thirty-two confederate towns gave the whole coast as far as the Hellespont into the hands of Philip. The next step to take was to obtain a footing in the internal affairs of Greece, and this he succeeded in getting, as far as northern Greece was concerned, in the Sacred War (355). Thebes having in vain endeavoured to impose its supremacy on Phocis, abused its influence over the Amphictyonic Council to declare a sacred war against the Phocians. The latter found assistance at the hands of the tyrants of Pheræ in Thessaly, and the aristocracy of Thessaly consequently placed themselves under the protection of Macedonia. Meanwhile, even Athens had at last given ear to Demosthenes' denunciations of Philip, and opened her eyes to the danger which threatened her, when her own colonies were captured by Philip; and war had been declared, though not immediately waged, against Philip by Athens. But the Sacred War ended (346) in the destruction of the Phocians, and Athens having ruined herself by procrastination—concluded a peace with Philip which confirmed all his gains and ratified all her losses. As yet Philip had found no excuse for interfering with the affairs of the Peloponnese; but this was afforded him in 344 by an ill-timed revival of Sparta's pretensions, which drove Messene, Argos, and Megalopolis into the arms of Philip, in spite of Demosthenes' propaganda in the first two places. In 340 Athens, having formed extensive alliances, felt strong enough to openly declare war against Philip. In 339 she saved Byzantium from his attacks, and thereby kept open the route by which her own corn came from the Black Sea. In 338 she at length (and too late) consented to Demosthenes' proposal to convert the moneys hitherto devoted to public amusement to military purposes. But the fatal field of Chæronea was followed by the peace of Demades. Philip was acknowledged master of Greece, and elected general of the Hellenic forces against Persia; but before he could commence his invasion of that country he was assassinated by a private enemy (336). A general rising against the Macedonian power was promptly nipped in the bud by Philip's son and successor, the world-famous Alexander. His first act was to suppress the attempted revolt by utterly destroying Thebes. In 334 he commenced his invasion of Persia. We can but enumerate his chief victories: in 334 his victory at Granicus gave him Asia Minor, on this side of Mount Taurus; in 333 he defeated Darius in the battle of Issus; in 332 he stormed Tyre and Gaza and founded Alexandria; in 331 he finally overthrew the Persian empire in the battle of Arbela; in 326 he crossed the Indus, but farther his troops refused to follow him. He then sailed down that river to the Indian Ocean, and thence marched to Babylon, where, while preparing to invade Arabia, he fell ill and died (323). Alexander not merely conquered Asia Minor—he planted Greek colonies in it, and these centres of culture discharged functions of the highest importance in the history of the world. They gave to Greek culture, Greek literature, thought, and art, even to the Greek language itself, a career independent of and unaffected by the fate or decay of Hellas itself. They made Greek the language of the civilised world, though it is true that it was not pure Attic, but the 'common' dialect, Hellenistic Greek—yet the language of the New Testament. In Alexandria were sown seeds for the fruits of which we refer to the section on the literature. Finally it was from these colonies that the Mohammedans made their acquaintance with Greek learning; so that in the time of darkness, when the very tradition of Greek learning had perished from out of western Europe, the Mohammedans were busy annotating Aristotle even in Timbuctoo.

The death of Alexander was the signal for a fresh struggle for independence; but this, the Lamian, war ended with the battle of Crannon (322) in the victory of the Macedonian general Antipater and the extinction of political liberty in Greece. In the struggles between the Diadochi ('the successors') for empire, Greece was the battlefield. Even when the various generals had made themselves monarchs of the kingdoms into which Alexander's empire split, and Greece was left unappropriated, the efforts of a statesman such as Demochares to obtain a position of independence for Athens by playing off one monarch against another were fruitless. All that lends interest to the next period—that of the Epigoni—is that a new form of political coalescence—federation—was tried, and with some success, by the Ætolian and Achæan leagues. But the centrifugal tendency in Greek politics was manifest in Sparta's

refusal to join the latter league, which thereon invoked the assistance of Macedonia. Macedonia's interference between Rome and Carthage led to the defeat of Philip V. at Pydna, 168 B.C.; and in 146 Corinth was destroyed by Mummius, and Greece became in fact, if not at once in form, a province of the Roman empire. As such there is nothing here to say of it. Nor at a later time has Greece a history separate from that of the Byzantine empire (q.v.). In 330 A.D. Constantine was converted to Christianity, and founded a 'new Rome' in Constantinople. In 395 Greece was ravaged by the Goths under Alaric. In 747 a great pestilence depopulated large parts of the country, into which Slavonic tribes immigrated. In 1018 the Bulgarians laid the country waste, but were finally defeated by Basil II. The final separation of the eastern and western churches took place in 1053.

In the year 1453 Mohammed II. made himself master of Constantinople and, amongst other portions of the empire of the East, of Greece proper. Cyprus and Crete (which had been in the possession of the Venetians) and the other Greek islands gradually passed into the hands of the Turks, Crete coming into their power in 1669. Twenty years after, the Venetians again began war in the hope of regaining their Greek possessions, and succeeded in winning back the Peloponnese only to lose it again in 1715. Under Turkish rule the Greeks were allowed to become comparatively wealthy, as in the Turkish empire the function of the subject races is to provide for the sustenance of the ruling Turks. With wealth came the spread of education and culture, and a revived consciousness in the Greeks of what mighty dead they were the descendants. Thus the soil was gradually and naturally prepared for the seeds sown by the French Revolution; and in 1821 the war of independence broke out. In less than a year the Turks were turned out, and Greek liberty recovered. But civil war ensued; nor was this unnatural. The leaders of the revolution were men who had acquired what capacity they had for leading in the service of the Turks, and had acquired it therefore in a bad school. The cold suspicion with which the struggle for liberty had at first been watched by Europe was eventually exchanged for warm sympathy and pity, owing to the horrible cruelties perpetrated by the Turks; so that when in 1824 the latter, by the aid of troops from Egypt, succeeded in regaining possession of Greece, there were not wanting volunteers from England and elsewhere to lead and fight amongst the Greek forces. In 1827 the Turkish fleet was destroyed at Navarino by the fleets of England, France, and Russia; by French aid the Turks were driven out of Greece, and in 1828 the Greeks had once more regained their liberty. In 1832 Otho of Bavaria was made king; but he ruled despotically, and in 1862 had to leave Greece in consequence. A son of the king of Denmark, born in 1845, was then made king under the title of George I., when the Ionian Islands (q.v.) were given back to Greece. He lost popularity by his unwillingness to be forced by the popular will into war with Turkey. The Berlin Treaty added a large area in Epirus and Thessaly to Greece (see TURKEY); and under George the country, in spite of mismanaged and embarrassed finances and frequent ministerial crises, was fairly prosperous till the disastrous war with Turkey in 1896. During the troubles in Crete the Greeks sent an expedition thither (in February); early in April 1500 irregular Greek troops crossed the Macedonian frontier; and the Sultan declared war on 18th April. The Turks not merely drove the invaders out of Macedonia and Epirus, but after a brief series of engagements, disastrous for the Greeks, occupied Larissa and other main points in Thessaly. The war came to an end about the middle of May, and peace was ultimately arranged, with a slight rectification of the frontier in Turkey's favour, and the payment of a war indemnity of £4,000,000, guaranteed by the Powers—the Greek customs meanwhile to be controlled by an international commission.

Modern Greece.—The legislative power is vested in a single chamber, which consists of at least 150 paid representatives, elected under the ballot by universal suffrage for a period of four years. Greece is divided into sixteen nomarchies or departments, which are again subdivided into eparchies and demarchies. The Greek Orthodox Church is established by law, and to it the great mass of the people belong (see GREEK CHURCH); but there are some 25,000 Mohammedans in Thessaly and Epirus. There are some 160 monasteries and nunneries, with 2600 monks and 500 nuns. Elementary education is compulsory for children between five and twelve; but the law is not enforced outside the towns. Of the army recruits 30 per cent. are illiterate, and only 15 per cent. can read. The revenue is between £3,000,000 and £4,000,000; but usually the actual expenditure has greatly exceeded the revenue. The total debt amounts to £33,000,000, without the last war indemnity. Fully a third of the expenditure is absorbed by the interest on the debt, and a fifth by the ministries of war and marine. The nominal strength of the army on a peace footing is 25,000—which in war is raised to 100,000; all able-bodied males are liable to service. The navy consists of four small ironclads, sixteen gunboats, twenty-one torpedo boats and launches, with nearly 3000 officers and men.

In 1879 the area of Greece was 19,809 sq. m., with a population of 1,679,775 (1,457,894 in 1870); the Thessalo-Epirot districts incorporated with the kingdom in 1881 (as an outcome of the Berlin Treaty) added to this a territory of 5161 sq. m., with a population of 299,677; total, 24,970 sq. m. (less than half the area of England), with 1,979,452 inhabitants. At the census of 1889 the population was 2,187,208. Besides the Greeks of the kingdom, the Greeks in various parts of the Ottoman empire —notably in Constantinople, Macedonia, the western parts of Asia Minor, Crete, Cyprus, and the smaller islands—number above 6,000,000. Most of the Albanians who have migrated into Greece have been completely Hellenised; the non-Hellenised Albanians in Greece number about 100,000. In Greece there is an excess of males over females in the proportion of 107·6 to 100. Athens, the capital, has a population of 110,000; the towns next in size being Patras, Piræus, Hermupolis, and Corfu, all above 20,000; and there are four others between 20,000 and 10,000. Greece, although one-half of its area is pasture-land or waste, is mainly an agricultural country; but the land is mostly in the hands of peasant proprietors; agricultural machinery is unknown in many districts, and the implements of husbandry are of the most primitive type. Besides cereals, fruits, sugar, tobacco, cotton, and dyestuffs are raised. The chief articles of export are currants (about half of the total, though depression in this trade has of late years caused great distress), lead and other ores, olive-oil, wine, honey, sponges, &c. The principal imports are cereals and textile goods. The exports have an annual value of about £3,000,000; the imports are valued at £4,400,000 a year. Nearly a third of the total trade is with Britain, and about one-seventh each with Russia and France. The herding of sheep (3,465,000) occupies about 9 per cent. of the people; the sponge and coral fisheries employ more than 900 boats. The minerals of Greece include lignite, argentiferous lead, zinc, magnetic iron, and marble. In 1895

there were some 1200 flour mills worked by water and wind, and less than 100 by steam; over 200 distilleries; and numerous dye works, tanneries, and manufactures of machinery, cotton and silk goods, &c. 570 miles of railway were open, and 300 in course of construction; and there were nearly 4900 miles of telegraph lines. For the canal across the isthmus of Corinth, see CORINTH.

Literature. The distinguishing characteristic of classical Greek literature and the clue to its development is the fact that it was oral, that it was in all cases composed not to be read with the eyes, but to be delivered by the lips and heard by the ears. It is the distinguishing characteristic, because when Greek literature ceased to be oral it ceased to be classical; and it affords the clue to the evolution of classical Greek literature, because that literature went through a series of forms—epic, lyric, and dramatic, historical, oratorical, and philosophical—which forms were impressed on it by the changing nature of the circumstances under which the composer addressed his audience. These circumstances varied not capriciously but directly with the change of social and political conditions. Thus, in ancient Greece the form of literature prevailing at any given period was the expression and outcome of the form of society existing at that time; and hence the history of the literature is but one aspect of the history of the people. That the place and occasion on which an audience is gathered together determines the form of that which is addressed to it is plain enough in the case of a sermon and a play. That it was not the author who determined whether a play or an oration should be most popular is explained by the fact that it is the great public which it is most artists' ambition to please; and it was circumstances which decided that the great public in Athens should be found at one period in the law courts rather than in the theatre, at another in the theatre rather than in the law-courts. When political liberty was extinguished in Greece there ceased to be a great public, works were composed for the approval of learned and narrow cliques, and classical Greek literature was at an end. Without a great public, no great artist.

We now propose to trace the successive forms through which classical Greek literature went, and to show to what social and political causes these were due. For details as to the lives and works, and for criticism on the genius, of individual authors, we must refer to the articles in which they receive individual attention. In the literature of Greece, as of other countries, verse preceded prose, partly because the pleasure verse gives to the ear is much more pronounced and more easily produced, and partly because verse is so much more effectually retained in the memory a point of cardinal importance when writing is as yet unknown. Of poetry, the first form to appear in Greece was epic. An epic poem is a narrative poem; and the epics of Homer—the only epics that have come down to us, though by no means the only epics composed—are of considerable length. This fact, which has been regarded since Wolf as indicating that the poems could not have existed at such length when writing was either unknown or not used for literary purposes, is really the best proof that they belong to the most ancient period of Greek literature. That poems as long as those of Homer may be handed down by memory is beyond doubt. The question is when and where could a public have existed for whom we may suppose them to have been composed? They cannot indeed have been recited at a single sitting; therefore they cannot have been composed for audiences such as those at the great Greek festivals. They must have been composed for an audience small enough to be gathered together night after night until the whole had been recited. Further, the audience must have been such as it was a pride for the artist to address. The only audience which satisfies all these conditions is that which is occasionally described in the Homeric poems themselves, that gathered in the hall of the chieftain of the village-community, which was the earliest form of Greek as of English society. At no other period in Greek history was there an audience for whom we can conceive a poet composing such poems as those of Homer.

When in the natural course of development the village-community expanded into the city-state, the village chieftain's hall ceased to be the centre of society. 'Society' now consisted of the members of the aristocratic or oligarchic families. They cared not to hear of the past glories of the heroic ancestors of those chieftains whom they may themselves have helped to turn out of power. Nor was the same audience gathered together night after night in any great house; *symposia*, or drinking-parties, were indeed given frequently, but the guests were not the same on each occasion. Song again was as much in request as wine at these drinking-parties, but the songs were from the nature of the case short, their subjects drawn from the present, not from the past, and their most frequent themes, love, wine, and politics. In a word, the second form assumed by Greek literature was that of lyric poetry—the lyrics of Sappho, Alcæus, Anacreon, Archilochus, Ibycus, Theognis. There was indeed another form of lyric, which was choral and religious; and it needs special mention, not because its genesis differed essentially from that of other lyric poetry, for it also was composed for a special occasion, with reference to the present and under circumstances which precluded length of treatment, but because from it was developed the third form of Greek verse literature—the drama. Choral lyric might celebrate the victory of some athlete at the national games, or the mighty works of the god at whose festival the poem was designed to be performed. The odes of Pindar which have come down to us belong to the former class. To the latter class belong the odes addressed to Dionysus (q.v.), the god of wine, from which the drama was evolved. Unfortunately of these odes, dithyrambs, we have not a specimen. Simonides of Ceos, Arion, and Alcman were the great composers of this class of lyric.

That an ode relating the adventures of a god should first be accompanied by sympathetic gesture and action, and should then come to be really acted, is readily comprehended. And that the gestures should be especially realistic at the festivals of the god of wine is not hard to believe. But it is not probable that literary form would have been given either to the more or to the less solemn side of this piece of ritual had it not been that present on these occasions was a public greater than any that a poet had hitherto been able to address—i.e. the whole of the community gathered together for an act of public worship. The development of the drama was the work of democracy. A greater audience was provided at the public festivals of a democratic state than could be found in the house of any oligarch; and genius at once deserted the form of literature adapted to the symposium for that by which it could reach the ears of the people at large. At the same time the drama, though it required other powers as well, afforded scope for the exhibition of both epic and lyric power. The chorus, out of which the drama grew, was still retained in the drama; and thus lyrics were an essential part of the play. On the other hand, much of a Greek play consists in the narrative of what has occurred off the stage. The number of

dramatic poets produced by Greece was very great; for us the tragedies of Æschylus, Sophocles, and Euripides—The Three—and the comedies of Aristophanes, are the Greek drama.

But the drama is not the only form of Greek literature for which we have to thank Greek democracy. To it we owe all three forms of prose literature—history, oratory, and philosophy. For now at length, after composition in verse had been practised for some four centuries, composition in prose was attempted, which—seeing that the Greeks had spoken prose all the time, even as M. Jourdain—seems strange. In fact, however, a really original idea, indeed even a moderate departure from what 'is always done' on a given occasion, is not of frequent occurrence in the history of the world. The mere conception that it was possible to compose otherwise than in verse seems not to have occurred to any one. Then, to put on paper a series of connected ideas, when one has them, is not a matter of absolute ease and simplicity. It is quite conceivable that it may have been easier to write in verse than in prose; the earliest philosophers Xenophanes, Parmenides, Empedocles apparently found it so. When, however, the idea of prose composition had been once struck out, it was, thanks to the encouragement afforded by the great public, rapidly worked out in various directions. So rapidly indeed that it is difficult to say whether oratory, though distinctly posterior to history, is or is not to be ranked as earlier than philosophy. As, however, the style of the greatest writer of philosophy, Plato, would certainly not have attained the perfection it displays had not some of the orators previously demonstrated what could be done with the language in certain directions, we may consider philosophy to be the latest of the three forms of Greek prose literature, and to correspond to the latest of the three forms of Greek verse literature, the drama, in that each resumes in itself the two forms which precede it. Narrative and argument both find their place in philosophy, as lyric and epic in drama. Oratory, like lyric, is the expression of the individual man dealing with the present. Prose begins with narrative in the form of history, as verse begins with narrative in the form of epic.

Again, it is somewhat difficult for us to realise that history could have been composed for oral delivery. But the fact remains that, though in the time of Xenophon, the most recent of the three historians whose works have survived, there was a trade in books, at the time when his predecessors Thucydides and Herodotus composed their works there was no reading public for whom they could have intended their histories. Herodotus, the 'father of history,' probably recited his at the great national festival of the Olympian games. Thucydides as much as states that he wrote for posterity, and implies that in so doing his design was singular.

In the case of oratory, the essentially oral nature of this form of literature is patent. That it should have been developed as a form of literature when it was is due on the one hand to the cultivated taste of the democratic *dicasts* or jurors, who demanded literary merit in the speeches addressed to them, and on the other to the frequent access to the great public afforded by the law-courts to aspiring genius. The accident that at Athens a suitor was compelled himself to speak on his own behalf, and therefore evaded the intention of the law by getting a professional speech-writer to compose a speech for him to learn and deliver as his own, did much to open the law-courts to literary genius and to develop eloquence. Of the orators we are fortunate enough to have considerable remains—of Antiphon, Andocides, Lysias, Isocrates, Isæus, Æschines, Hyperides, and, greatest of all, Demosthenes.

Finally, the third form of Greek prose literature, philosophy, was essentially oral. Socrates, who gave to philosophy the direction it has followed to this day, never wrote a word. Plato and Aristotle lectured, and if they also wrote, it was that their written teaching might be read aloud in the schools they founded, after they were gone.

In nothing is the post-classical period of Greek literature more remarkably distinguished from the classical than in the fact that we no longer find one form of literature cultivated at a time, but all kinds simultaneously. If the term 'post-classical' is sometimes employed, and sometimes justly resented as being almost a term of reproach, it must be admitted on the one hand that Theophrastus, Theocritus, Menander, Plutarch, Lucian, are names that would adorn even a 'classical' period, and on the other that, notwithstanding these great names, the post-classical period created no new form of literature, that, viewed as a whole, it can point to no progress made in any of the forms already created, and that all its activity, which was enormous, was in the direction of deterioration. When we pass from the classical period to the post-classical we have as our guiding principle not development but decay. In the Alexandrine period (332–146 B.C.) this is less notable than in the ages which succeeded it up to the fall of Byzantium (1453 A.D.), though it is unmistakable. The Alexandrine period is so called because Alexandria, the colony founded by and named after Alexander, became, thanks to the learned liberality of the first three Ptolemies, the seat of two great libraries, and the greatest centre of literary culture. But though the greatest it was by no means the only such centre of culture in the age to which it gives its name. Egypt was not the only one of the kingdoms that rose from the ruins of Alexander's empire which could boast of a literary capital supported by the liberality of its kings. Antiochia, Pella, and, above all, Pergamum, vied with Alexandria; and the rivalry of Pergamum was only extinguished when Antony sent its magnificent library of 200,000 volumes as a present to Cleopatra. But before this Pergamum had had time by its cultivation of rhetoric to affect Rome and Roman oratory in no small degree. Nor were the true Greek abodes of literature at once deserted by the Muses during this the first period of decline. In Athens the new comedy, with Menander for its great representative, and philosophy, with Theophrastus as its chief, still flourished. In Syracuse there was developed, not indeed a new form of literature, but a new mixture of ancient forms—bucolic poetry, which is a mixture of the narrative and the dramatic forms, while, although the (usual) employment of the hexameter might approximate it to epic, the recurrence of a refrain gives it a lyrical air. History can be said to exhibit, at the most, incipient decay in a period which can point to Polybius, to say nothing of Berosus and Manetho; and epigrammatists were numerous. Aratos indeed, the greatest of Alexandrine didactic poets, and Apollonius, the greatest epic poet of this period, have done nothing that they should be compared with 'classical' writers of hexameters. But it is not on its poetry that Alexandria can base its claims to our gratitude; it is on all that the librarians of Alexandria did to preserve the stores of classical literature.

Succeeding ages produced several respectable prose-writers—Pausanias the archæologist, Arrian 'the second Xenophon,' Josephus the historian—and two great prose-writers, Plutarch and Lucian; but in poetry they were yet more barren than the Alexandrine period. Again, a string of lexicographers and grammarians—Julius Pollux, Hesy-

chius, Suidas, Photius did valuable work on the classics. In fine, the post classical period was critical, not creative; it cared more for matter than for form, its poetry was based on classical models, and was generally frigid and pedantic, as its learning, though spent upon the classics, was not unfrequently pedantic and puerile; in two words, its chief features are imitation and annotation.

Compositions in modern Greek have been found dating from before the fall of Constantinople, but modern Greek literature is counted to have begun after 'the conquest.' For the first three centuries, however, we do not find prose works written in the modern language. We find poetical versions of Western romances, and we find the famous Klephtic songs, the songs of the Greeks who, rather than submit to Turkish rule, took to the mountains and lived a life of liberty, if of brigandage. But the prose works of this period are written in ancient Greek. If the rule of the Turk produced the songs of the Klephts, the dominion of Venice allowed of the production of poems which possessed more literary form though less poetical merit than the Klephtic chants. Such were the *Erotocritos* of Cornaro, an epic, or rather a pastoral poem, rather lacking in interest, and only occasionally relieved by a touch of imagination, and the *Erophile* of Chortakis, a tragedy defective in form, though containing lyrics of some value. In the 18th century poetry declined to a still lower level; and the honour of literature was chiefly maintained by the erudition of ecclesiastics, such as Lucaris, Miniatis, Meletios, Theotokis, Bulgaris. With the 19th century, however, began a new era in the history of modern Greek literature, and this was mainly the work of Corais (q.v.), himself the greatest name in the era which he inaugurated. Since his time the number of authors Greece has produced is strikingly large, some writing in modern, others in 'correct' Greek. Of them we may mention Panagiotis Sontsos, whose best work is contained in his dramas; Alexander Sontsos, the satirist; Rigas, the author of the song translated by Lord Byron, 'Sons of the Greeks, arise,' and of other poems which were the clarion whose notes still echoed in 1821 and first roused Greece from her slumbers; Villara, the lyric poet; Christopoulos, the Anacreon of modern Greek; Neroulos, the tragedian, distinguished for the fire of his imagination and the force and vigour of his diction; and last, the great scholar and still greater poet, A. R. Rangabé.

On the land of Greece, see W. M. Leake, *Travels in Northern Greece*, Wordsworth, *Greece*, Tozer, *Geography of Greece*, Lolling, *Hellenische Landeskunde und Topographie*, Bent, *Cyclades*, Freeman, *Studies of Travel in Greece and Italy*, Jebb, *Modern Greece*. On the history, works by Mitford, Thirlwall, Grote, Curtius, Holm, Cox, Smith, Evelyn Abbott, Duruy, Finlay (from the Roman Conquest, and Trikoupes, the War of Independence, in Romaic); Jevons, *Athenian Democracy*. On the literature, books by Muller, Cox, Mure, Mahaffy, Sittl, W. Christ, Susemihl, and the present author; and for modern Greek literature Rangabé, books by Miss Garnett (on folk songs) and Miss M'Pherson (poetry). For old Greek life, Becker's *Charicles*, and various works by Mahaffy. For the people of modern Greece, Rennie Rodd's *Customs and Lore of Modern Greece*, Miss Blunt's *People of Turkey*. Greek Architecture. The origin of what is popularly called Greek architecture is, like the origin of every art and science in that country, mixed up with mythical and fabulous history. It is divided into three styles, and each of these has its mythical origin. Thus, the Doric is said to have been copied from the early wooden huts of the aborigines; the Ionic, which sprung up among the Greek colonists in Asia Minor, to have been modelled on the graceful proportions of the female figure, as the Doric had been on the more robust form of a man—the volutes representing the curls of the hair, the fluting the folds of the drapery, &c. The story of the origin of the Corinthian style is very pretty: a nurse had deposited in a basket on the grave of a departed child the toys she had amused herself with when alive. The basket was placed accidentally on the root of an acanthus, and in spring, when the leaves grew, they curled gracefully round the basket, and under a flat stone which was laid on the top of it. Callimachus, the sculptor, seeing it, caught the idea, and worked out at Corinth the beautiful capital since called after that city.

Modern discoveries, however, have shown that Greece owed much to the earlier civilisation of the countries which preceded it in history. To the architecture of one or other of these, almost every feature of Greek architecture can be traced. But it is for the first idea only that the Greeks are indebted to Egypt and Assyria; whatever forms they adopted, they so modified and improved as to transform them into a new style. The so-called Cyclopean or Pelasgian (q.v.) architecture was wholly unconnected with the evolution of any style of Greek architecture subsequently developed. Its remains consist mainly of tombs or 'treasure-houses'—underground chambers, vaulted with overlapping stones, and approached by a narrow passage descending to the entrance-doorway. The interior was sometimes ornamented with plates of bronze attached to the masonry. The entrance-doorway was of a conical form, the upper portion being sometimes filled with sculpture, as in the well-known Gate of the Lions at Mycenæ. The ancient cities and tombs of Greece have in recent years proved a rich field of research. Schliemann's excavations at Mycenæ and Tiryns have brought to light a great number of specimens of very ancient art in the form of terra-cotta work, gold and silver smiths' work, and carved stonework. Whether native or imported, these show a strong affinity with Assyrian and other Eastern designs. The later Greek art took its rise under the Dorians, after the return of the Heraclidæ about 1100 B.C.

Greek architecture proper is divided into three styles—the Doric, Ionic, and Corinthian (see COLUMN, figs. 4, 5, 6). Of these the Doric is the oldest. The earliest example which remains is the

Fig. 1.

temple at Corinth, which was built about 650 B.C. The remains of this temple show the various members of the style fully developed, but they are all of a massive and heavy description, strongly resembling in this respect their prototype the architecture of Egypt. There is now no doubt, although the intermediate steps are lost, that the Doric style

took its origin from the rock-cut tombs of Beni-Hassan (q.v.) in Egypt, of which fig. 1 is an existing example. The pillars of this tomb appear at first sight to be Doric; it is only on close inspection that we find that the echinus (see MOULDING) is wanting under the capital. The echinus was, however, used by the Egyptians. We here find ourselves in the cradle of Greek art; here we must seek for the primitive elements of the style, not in Greece, where the earliest example is already complete in all its parts. There, the earlier the example, the more massive is the form. This completely disproves the theory that the pillars were copies of stems of trees used as posts. In Assyrian and Hindu architecture evidence is preserved in the forms of the bracket capitals of the wooden origin of the pillars and beams, but in Greek architecture there are no such indications. It seems more likely that the first pillars in Egypt were square piers of rubble or brickwork, with a flat stone or tile laid on the top to form a good bed for the beams to rest on. The lintels or architraves are short and massive, and the pillars are placed close together, as would naturally be the arrangement in stone construction. It has been supposed that the triglyphs represent the ends of wooden cross-beams resting on the architrave. But when the principles of Greek construction are analysed it becomes apparent that the triglyphs have been employed as stone supports set upon the architraves for the purpose of carrying the cornice, the mutules or spaces between the triglyphs being sometimes left open, although generally filled with sculptured slabs. It is also to be observed that the triglyphs are used on the ends as well as the sides of the temple, where they could not represent the ends of cross-beams. The rafters were certainly of wood, and gave their sloping form to the pediment. It seems also likely that the ends of the rafters and projecting roof-tiles at the eaves may have suggested the detailed features of the cornice with its modillions. It will, however, be observed that although the mode in which stone is employed in Greek architecture is quite appropriate for that material when the space to be spanned is small, still the *principle* involved is the trabeate one, or that of beam construction, which is more applicable to wooden framing than to stonework, for which the arch is the proper medium both of construction and expression. The square form of the pier may have been afterwards modified by cutting off the corners, and again cutting off the remaining corners, until the polygon suggested the fluted shaft. The same process was afterwards gone through by the medieval architects in developing the piers of Gothic architecture. Be this as it may, the circular and fluted form of the column had been developed before it was adopted in Greece.

After the temple at Corinth, the next remaining example is the temple at Ægina (q.v.), built about a century later, or 550 B.C. There may have been many temples of the same date, but none now exist; they were probably destroyed during the Persian war, or removed to make way for finer edifices during the great building epoch of Greece which succeeded that war, and when she was at the zenith of her power. Of this epoch we have many remains. The temple of Theseus and the Parthenon at Athens (438 B.C.), those of Zeus at Olympia (440 B.C.), Apollo Epicurius at Bassæ, Minerva at Sunium, and all the best examples of the Doric style of Greece are of the age of Pericles. Besides the Peloponnesus, there are the countries colonised by the Greeks to which we can look for remains of Greek architecture. The Dorian colonists of Sicily and Magna Græcia carried with them the architecture of their native country, and furnish us with many fine examples. In Selinus there are six temples, the oldest being about the same age as that at Corinth. At Agrigentum there are three Doric temples, one of them founded by Theron (480 B.C.); this is the largest Grecian temple of the period, being 360 feet long by 173 feet broad. At Syracuse, Ægesta, and Pæstum there still remain valuable examples.

As the Doric art progressed, the early massive forms gave place to more elegant and slender proportions. In the temple at Corinth the column is only 4·47 diameters in height; in the Parthenon (fig. 2), which is universally recognised as the finest

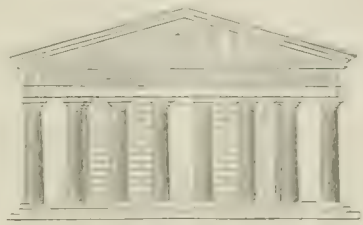

Fig. 2.

example of the style, the column is 6·025 in height; and in later examples it becomes still taller and thinner, until it runs into the opposite extreme from which it started, and becomes so meagre and attenuated as to lose entirely the boldness and vigour of design which are the chief characteristics of the style.

One thing to be particularly admired in the Doric style is the beauty of the sculpture with which it is adorned, and the appropriate manner in which the sculpture is placed in the building, and the building suited for the sculpture. Mr Penrose has endeavoured to prove by elaborate measurements and drawings that every line was the subject of the deepest study on the part of the architect, for the purpose of correcting and allowing for all optical aberrations. The result is that there is hardly a single straight line in the building; all the lines which *appear* to be perfectly straight are drawn with accurately calculated curves, so as to produce the smoothest and most pleasing effect to the eye. Every harsh angle is softened, and every disagreeable combination of lines avoided. For example, the columns instead of straight sides have an entasis or slight swelling formed by a hyperbolic curve; the architrave of the front is curved upwards, so as to correct the optical illusion caused by the sloping lines of the pediment, and the columns are sloped slightly inwards so as to give greater appearance of solidity. It must, however, be stated that in the part of Durm's *Handbuch der Architectur* (1881) which treats of Greek architecture, this extraordinary refinement of details is to a great extent denied. The Parthenon is built entirely of white marble, and the whole of the masonry in this, as in other Doric works of importance, is put together with the most perfect workmanship. There seems to be no doubt that this and other Greek temples were adorned externally with colour. To what extent this decoration was carried is not clearly ascertained; but it is probable that the exterior walls were covered with historical pictures, which were sheltered from the effects of the weather by the portico surrounding the temple. This colouring also served as a background against which the white-fluted pillars would stand well out. The sculpture was probably also relieved by a flat colour on the background, and the mouldings decorated with painted or gilded ornaments.

Ionic.—This style took its rise about 500 B.C., and as we have seen that the earlier Doric was

imported from Egypt, so the Ionic seems to have originated from the influence of Assyrian art. The discoveries of Layard and others have shown that many of the characteristic ornaments of the style were in common use in Assyrian architecture. The volutes of the capitals are particularly indicative of an eastern origin, the scroll being an ornament of very frequent occurrence in all eastern art. The finest examples of the Ionic style remaining in Greece are the temples of Wingless Victory (Athena Nike) and the Erechtheum at Athens, both about 450–420 B.C. In the Ionian and other colonies of Asia Minor also many fine specimens of this style were erected. The celebrated Temple of Diana at Ephesus was of the Ionic order. It was the largest temple we know of up to its time, being 425 feet long by 220 feet wide. The site was discovered and excavated by Mr Wood in 1869–74. The Ionic is a graceful and elegant style, but not so pure and severe as the Doric. The latter is distinguished by simple and beautiful outline, enriched with the most perfect sculpture; the former trusts rather to ornamental carving for its effect. This love of elaborate ornament is an indication of the eastern influence under which the style originated, and the mouldings and many of the ornaments are found to be borrowed from those of Assyrian architecture, only refined and simplified by the Greeks. The honeysuckle ornament (fig. 3), so commonly used both in Assyrian and Ionic architecture, is a good example of the improvement effected by the Greeks on the original type. In the Ionic as well as in the Doric, we find the most perfect execution and workmanship, the spirals, entasis, &c. being all drawn and cut with the greatest possible exactness.

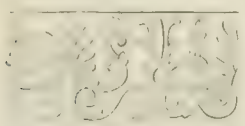

Fig. 3.

Corinthian.—This style was the latest introduced, and combines to some extent the characteristics of both the preceding. It unites and blends together the Egyptian and Assyrian elements, the cap being probably derived from the bell shaped capitals of the former country, ornamented with the carved leaves and spirals of the East. This order was first used about the time of Alexander the Great, the earliest example extant being the Choragic Monument of Lysicrates (335 B.C.). There are also the Temple of the Winds and that of Zeus Olympios at Athens, the latter being one of the largest and finest examples of the style. The Corinthian is the most florid of the Greek styles, and although invented by the Greeks, it was not brought into use till after the power of the republics, to which we owe the finest works of Greek art, had begun to wane. This style, from its richness and splendour, became afterwards the greatest favourite with the Romans, in whose hands Greek art spread over the whole empire.

Caryatides.—Besides the above styles, which constitute *the Greek orders* of classic writers, the Greeks also used *Caryatides* (q.v.), or female figures, in place of columns, as in the Erechtheum: and *Telamones* or giants, as at Agrigentum. These were probably derived from the figures used by the Egyptians in their architecture, but the latter never used them as columns; they always placed them as statues in front of the columns.

Fig. 4.

Greek temples are technically classed and designated by the mode in which the columns of the porticoes are arranged. The *cell*, or temple proper, is a square chamber contained within four walls; the simplest form of portico is called *distyle in antis* (fig. 4), the two side-walls being continued past the end-wall, and terminated with antæ, or pilasters, with two columns between. When the portico has four columns between the antæ, it is called tetrastyle. The temples have generally the same arrangement at both ends. In front of both ends of the plan *distyle in antis* (fig. 5), there is frequently placed a range of six columns, and from the flank columns a row is continued along both sides, thus forming a continuous portico all round the edifice. Such an arrangement is called *peripteral*, and the temple is designated hexastyle and peripteral. This was a common arrangement. The Parthenon is an exception to the general rule: it has a hexastyle portico at each end of the cell, in front of which is placed an octastyle portico, and seventeen columns at each side. The great temple at Agrigentum had seven columns at each end, and fourteen at each side, and was peculiar in having the space between the columns all round filled up with a wall. The reason probably was that the space between the columns was too great to be spanned by architraves in single stones. The wall was pierced with windows.

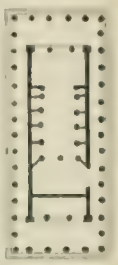

Fig. 5.

Considerable doubt has existed as to the mode adopted by the Greeks for lighting the interior of their temples; that suggested by Mr Fergusson seems the most probable, as being similar to the plan used by the Egyptians and Assyrians. The interior had generally a double row of columns, one over the other, dividing the width into three spans. This arrangement still exists in the Temple of Neptune at Pæstum. Fergusson supposes that the light was introduced by countersinking a part of the roof, so as to admit the light between the pillars of the upper range, thus forming a kind of clerestory, as shown on the annexed section of the Parthenon (fig. 6). Windows, however, were also used, as in the temple at Agrigentum and in the Erechtheum.

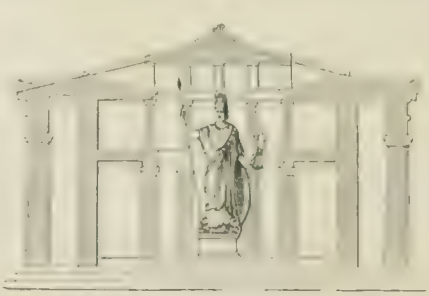

Fig. 6.

The theatres of the Greeks formed another very important class of works; they consisted of semicircular rows of seats cut in the rock, or partly built (see ATHENS). Remains of these structures are found in all the countries inhabited by the Greeks, and were frequently of great size—that at Dramyssus being 443 feet across. The proscenia were the parts on which architectural design was chiefly displayed; but these have unfortunately all perished.

None of the palaces or domestic edifices of the Greeks remain to us; we are thus totally deprived of a very interesting chapter in the history of domestic architecture, for it is highly probable that the houses of Greece, although not so splendid

and enduring as the temples, were more varied in style, and exhibited many picturesque and beautiful forms, which are now entirely lost. But from what is known of the jealous feelings which pervaded the republics of Greece, and from the aspect of the houses in the streets of Pompeii, we may conclude that the exterior appearance of the town-houses would be quite plain and unpretending, any richness or decoration being reserved for the interior.

The attempt was made in the early part of the 19th century to revive Greek architecture, and some ingenious modifications and adaptations of it have been carried out. But it was found that this style, so beautiful and appropriate in the warm and genial climate of Greece, was quite unsuited for our northern latitudes. The porticoes are useless in a climate where external painting cannot last, and where the sunshine is courted rather than excluded; the pitch of the roof is not high enough to throw off our snows; and windows of sufficient size for our dark skies are not admissible. Grecian architecture has therefore been abandoned; and its place is now taken by a style more appropriate to a northern climate, and more suited to the feelings of the people. See Fergusson's *History of Architecture* and other general works on the subject; *Antiquities of Ionia* (Dil. Soc. 4 vols. 1769-1881); *Athenian Architecture* (Dil. Soc. 1851; new ed. 1890).

Greek Church. THE (styled 'orthodox' by reason of its vindications of dogma, and 'Eastern' from its geographical distribution), is the church of those Christians who follow the ancient rite of the East and accept the first seven councils, but do not admit papal supremacy, and reject those innovations on the dogmas and the practice of the early church which were introduced by subsequent councils in the West. She is 'the aged tree beneath whose shade the rest of Christendom has sprung up:' and 'it is her privilege to claim direct continuity of speech with the earliest times, to boast of reading the whole code of Scripture, old as well as new, in the language in which it was read and spoken by the Apostles' (Stanley, *East. Ch.*). The dogmas of Christianity were first expounded by the Greek fathers; the earliest forms of Christian worship were composed by Greeks in Greek, and during the first five centuries the Eastern Church may fairly be said to have comprised the whole body of Christianity.

History.—The tendency and desire, natural to the Eastern mind, to endeavour to estimate and define in the abstract the attributes of Deity, pushed to extremes during a time of absorbing theological controversies, brought about, in the earlier period of the church, the formation of sects to which we shall hereinafter advert. But the great Schism between the eastern and western portions of Christendom, an event which has exercised abiding influence on the whole course of subsequent European history, was due to two primary causes—the inherent difference in the spirit and the traditions of East and West, and the transfer of the seat of empire from Rome to Constantinople.

As the Christian faith became predominant ecclesiastical jurisdiction necessarily coincided with civil government, so that, when the Council of Nicæa declared Rome, Alexandria, and Antioch to be patriarchal sees, it but recognised the political importance of those three centres of Christianity. As such, Rome was then the least important of the three. Indeed the early Roman Church was a colony of Greek Christians and Grecised Jews; the first popes themselves were Greeks, not Italians, and the very name of 'pope' is not a Latin name, but the Greek designation (*papas*) of every pastor of the Eastern Church. When, however, the seat of empire was transferred to Constantinople (330 A.D.), although Rome was thus deprived of its sovereignty and its courtly splendour, a signal opportunity for increase of power and self-assertion was given to the Roman pontiffs. Favoured by the absence in their diocese of theological controversies, such as distracted the East, and endowed for the most part with rare ability and worldly astuteness, they were not slow to seize upon and gradually appropriate the prerogatives and the civil authority of the absent emperors, and they soon arrogated to themselves even their pagan titles and military prestige. Constantinople, on the other hand, now rose rapidly to pre-eminence, not in the same sense of an ambitious ecclesiastical despotism, but as the official centre of a church already venerable, which had just received into its fold the first Christian emperor. A generation had hardly passed when Gregory Nazianzen (360) spoke of the city as a 'bond of union between East and West to which the most distant extremes from all sides come together, and to which they look up as the common centre and emporium of the faith.' It is true that, on the ground that 'Constantinople is the new Rome,' the second general council (381) assigned to it 'precedence of honour' next after Rome. But this declaration, and the subsequent decree of the fourth Council of Chalcedon (451), establish that these ecclesiastical honours were grounded upon the political distinction only to which both cities had successively risen. Jerusalem itself, in spite of its unrivalled associations, was included amongst the patriarchates—which thus reached the number of five—only at this latter council. Yet the initial advantages which the Greek Church already possessed never disappeared; they still subsist, 'a perpetual witness that she is the mother and Rome the daughter' (Stanley).

But other and irresistible inward causes militated against the maintenance of even outward unity. Rome was destined soon to detach herself from the sisterhood of patriarchates, and renounce even that venerated title. According as the political ties between the eastern and western halves of the empire grew weaker, antagonistic ideas seemed to guide the two rival sections of the church. In each the divergent genius of their pagan forerunners, no less than opposed local temperaments, reappeared with fresh vigour, and influenced both thought and action. The Greeks were still swayed, however unconsciously, by the liberal tradition of democratic Hellas; while the autocratic and centralising tendency of Rome never ceased to pervade the Latin pontificate. The fathers of the Greek Church inherited and christianised the philosophy of Plato and Aristotle; the Latin Church modelled its Christianity after Roman law. 'The East enacted creeds; the West discipline' (Milman). The one was controlled by a calm conservatism, the other was impelled by a restless desire for change. The one church remained ancient and catholic in spirit; the other was transformed into a medieval and Latin institution.

These contrasts, apparently superficial, were more deeply rooted and were fraught with weightier consequences than the outward theological differences which now mark the distinctions between other Christian churches. They were such as to lead to open rupture. Rome furthermore seemed again possessed by its traditional feeling of mingled jealousy and disdain for the Greeks, who were gradually becoming supreme at Constantinople, and who finally transformed the Roman empire into a Greek monarchy. Therefore, in the disputes which followed in quick succession, political considerations weighed more in proportion as the temporal power of the popes found sustenance in the gradual growth of an

independent confederation amongst the Italian states.

The first notes of disunion were sounded in Rome, by such innovations as the enforcement of clerical celibacy (385), followed by more or less peremptory demands for the recognition, first of the hierarchical, and later of the doctrinal supremacy of the Roman pontiff, which was ultimately to be admitted as 'by divine right.' Minor changes were gradually introduced into the Western Church, such as denying to priests power to administer confirmation, and the use of unleavened bread in the eucharist. These innovations the Greeks regarded as expressly designed to force upon them either a complete rupture or an unconditional submission to papal authority. But the chief and most abiding point of dogmatic difference consisted in the doctrine of the twofold procession of the Holy Ghost and the interpolation in the ancient creed of the church of the words *Filioque* ('and from the Son'). Without entering into the details of this interminable, hopeless, and bitter controversy, it may be safely said that the complete absence of such a doctrine from the deliberations of the early councils is not denied by the Latins; that popes, such as Leo III. and John VIII., admitted that its surreptitious insertion into the Creed was reprehensible; and finally, that the Greeks base their uncompromising reprobation of it on the explicit word of Christ: 'The spirit of truth which proceedeth from the Father' (John, xv. 26).

Such being the abundant sources of an estrangement which steadily increased, the pope was not at a loss for pretexts in hurling his first excommunication against the emperor and the patriarchs of Constantinople and Alexandria in 484. Thus the East and West were *de facto* separated for a period of nearly forty years. Efforts at conciliation followed, and successive excommunications were withdrawn to be renewed from both sides with intensified animus. But while the pope subordinated dogmatic differences to the recognition of his supremacy, the title of 'œcumenical,' which the emperor conferred on the patriarch of Constantinople, proved a fresh stumbling-block. The contest which followed (862) between the learned patriarch Photius and the popes Adrian I. and Nicholas I. was one of the most memorable periods of that long and eventful struggle, and although the so-called 'Photian Schism' was again compromised, the reconciliation proved neither cordial nor lasting. The same causes of difference, with others of a disciplinary nature, reappeared in the 11th century; and in 1054 Pope Leo IX. issued a formal excommunication against the patriarch Michael Cerularius. Since that time the separation has subsisted rigidly; for although more than one attempt was made by either side to restore intercommunion between the two churches, every effort failed before the unalterable demand for submission to papal supremacy and jurisdiction. Pope Gregory IX. conceded even the omission of *Filioque* by the Greeks, provided they burned publicly all books inimical to the Roman see; and the desire of many Greeks for reconciliation was so sincere that some sort of reunion might have been effected at a later time, if the old antipathies of East and West had not been rendered even more intense and irremediable through the conquest of Constantinople by the Latins in the fourth crusade (1204). The atrocities of this unprovoked and fanatical onslaught, which was instigated by the papal see, the outrageous desecrations of Greek churches, the horrors of the sack 'of a refined and civilised capital by a horde of comparative barbarians' (Stanley), and the cruel tyranny by which the Franks maintained their power, rendered the existing breach irreparable. The Frank invasion, by disorganising and weakening the Greek empire, opened the gates of Europe to the inroads of the Turks, whose rising power had carried before it everything in Asia. So that on his restoration to the throne of Constantinople (1261) the emperor Michael Palæologos, pressed by dangers, was compelled, on a promise of material assistance from the West, to submit to the dictates of Rome at the Council of Lyons in 1274. When, however, he endeavoured, at a synod held at Constantinople, to obtain ratification of that union, he failed to gain the assent of the body of bishops to what was a one-sided measure, resulting from political necessity. In the succeeding reign the breach was even more seriously widened by the councils held at Constantinople in 1283 and 1285. The last attempt at union was the one made by the Emperor John Palæologos, who, to save Constantinople, and with it the West, from the invasion of the Turks, appeared (1437) with the patriarch Joseph and several Greek bishops at the Council of Ferrara, better known from the place of its close as that of Florence. Protracted discussions took place on all the points at issue; but while received with marks of distinction and outward show of friendship, the Greeks were, as on former occasions, deceived, outreached, and entrapped into signing misleading and fraudulent documents, with the inevitable result that, even before their return to Constantinople, they renounced and repudiated the proceedings of what they characterised as one of the most scandalous of Roman conclaves. The capture of Constantinople by the Turks followed in 1453, and the fall of the Greek empire removed the political considerations which alone had dictated these latter attempts at reconciliation. Thus the Greek Church may be said to have died politically, but it has never surrendered its religious heritage.

Doctrines.—As already stated, the Greek Church receives the first seven œcumenical councils and the canons of the Trullan Council (from Τροῦλλος, the domed chamber of the imperial palace at Constantinople, where it was held). They adopt as their rule of faith not only the Bible, but also the traditions of the church '*maintained uncorrupted* through the influence of the Holy Spirit by the testimony of the Fathers,' amongst whom Basil the Great, Gregory Nazianzen, and St John Chrysostom are held in special veneration as 'the three hierarchs.' The Greek Church admits seven sacraments—viz. baptism, confirmation, penance, eucharist, matrimony, unction of the sick, and holy orders; but both in the acceptation and the use of them it differs widely from the Church of Rome. *Baptism* is administered by a triple immersion, in accordance both with the meaning of the term itself and with the indisputable practice of the early church. *Confirmation* (Μύρον or Χρῖσμα) follows immediately upon and in connection with baptism, even in the case of infants—again in obedience to apostolic precept. In the sacrament of *Penance* the church requires (*a*) admission before God of one's own sins, (*b*) faith in His mercy, (*c*) resolve of self-amendment: this confession to be made before a priest, (1) that he may offer spiritual guidance and admonition; (2) that he may announce to the penitent, in the name of Christ ('May the Lord absolve thee'), absolution and hope of salvation; (3) that he may recommend penitential work. 'Therefore the scandals, the influence, the terrors of the confessional are alike unknown in the East' (Stanley). As to the *Eucharist*, the Greeks admit the propitiatory sacrifice, the real presence of Christ, and transubstantiation, which, 'if used at all as a theological term, is merely one amongst many to express the reverential awe with which the eucharist is approached' (Stanley). They differ

from the Latins in the use of leavened bread and in the administration of communion in both kinds to all, even to children—this again in strict obedience to evangelical precept (John, vi.). *Marriage* is held to be dissoluble in case of adultery, but not till a probationary period has elapsed during which a bishop or priest mediates with a view to reconciliation. A fourth marriage is regarded as unlawful. *Unction* is administered not *in extremis*, as in the Latin Church, but in ordinary sickness, as laid down by St James (v. 14, 15), and is therefore called oil of prayer (Εὐχέλαιον). The sacrament of *Holy Orders* is celebrated by the observance of rites which have remained unchanged since the earliest times. With the exception of this last, all the sacraments may be administered by priests. The Greek Church not only reprobates clerical celibacy, but, although it has at all times favoured monastic orders, it requires that the parochial clergy should be married, so that they may not be cut off from the domesticity of the life of their flocks. Priests cannot marry after ordination, and consequently cannot contract a second marriage, nor may they wed a widow; but they must be married before ordination. Bishops are selected from the monastic orders, and are therefore single.

Monastic life originated in the East, and in countries of the Greek rite numerous convents of both sexes are established, most of which follow the rule of St Basil. The rule of St Anthony (the Egyptian hermit who first instituted Christian monasticism) prevails at Mount Sinai (established 527). This monastery, Jerusalem, and Mount Athos form the three great centres to which convents throughout the East are affiliated. According to their mode of life, monks are distinguished as (*a*) Ἀσκηταί, if leading the ascetic existence of hermits; (*b*) Ἀναχωρηταί, when living in retirement and in separate cloisters; and (*c*) Κοινοβιακοί, when assembled in a convent under an Ἡγούμενος or abbot. If several convents are subject to one abbot he is called Ἀρχιμανδρίτης, archimandrite; but bishops often hold the post of abbot. Nuns must either be virgins or widows, and they follow the rule of St Basil under an Ἡγουμένη, abbess. With both monks and nuns the duty of manual labour is a leading observance; the nuns, like their western sisters, apply themselves to the care of the sick and to the education of girls. But the chief glory of the Greek monastic institutions is that in them Greek learning and Greek nationality found refuge, protection, and succour during the long night of Turkish tyranny and Mohammedan persecution.

Worship and Liturgy.—Fasts in the Greek Church are many and rigorous. Besides four yearly fasts—the forty days of Lent, from Pentecost to the Feast of Saints Peter and Paul, the fifteen days before the festival of the Sleep of the Theotokos (August 15), and the six weeks before Christmas—Wednesdays and Fridays throughout the year should be observed. Indulgences are not recognised; and although prayers for the dead are practised they give rise to no ecclesiastical abuse. 'A general expectation prevails that, by some unknown process, the souls of the sinful will be purified before they pass into the Divine presence; but this has never been consolidated into a doctrine of purgatory' (Stanley). The Mother of our Lord is venerated, and homage (ὑπερδουλεία) is paid to her, but such homage has never been transformed into a dogma of immaculate conception; and the Greek Church speaks of 'the sleep' (κοίμησις) not the 'assumption' of the Virgin. Reverence (δουλία as distinguished from ἀληθινὴ λατρεία, actual worship) is paid to saints, and their *icons* freely adorn the churches; but, with the exception of the crucifix, no graven image is permitted. Instrumental music is forbidden in churches, but singing is universally in use. In public prayer the kneeling posture is used only at Pentecost; at ordinary times they stand, the body being turned towards the east, and the sign of the cross is frequently made during prayers. The ceremonial of the Eastern ritual is not inferior in splendour to that of the Western, but it is more solemn and archaic; though 'organs and musical instruments are as odious to a Greek or Russian as to a Scottish Presbyterian' (Stanley). Originally several liturgies were used in the East; but the liturgy of St James prevailed in the Greek Church. In its shorter form, as defined by St Chrysostom, it is read in churches throughout the year, with the exception of two or three festivals, when the longer version, attributed to St Basil, is said. This version is invariably used in convents. The Scriptures are in the hands of all believers, who are encouraged to study them in the vernacular, and although the idioms of some of the eastern churches into which the Bible as well as the liturgy were originally translated are now antiquated, 'the actual difference may be about that between Chaucer's English and our own.'

Hierarchy in the Eastern Church is thus defined in the catechism of Philaretus, which is in universal use in Russia: 'The four patriarchs, of equal dignity, have the highest rank among the bishops, and the bishops united in a general council represent the church, and infallibly decide under the guidance of the Holy Ghost all matters of faith and ecclesiastical life.' Thus the authority of the church is not despotic, centralised, or vested in one person. Each patriarch is independent in the exercise of his canonical authority, within his own diocese; but he is amenable to an œcumenical synod. The Greek clergy levy no tithes, claim no civil power over their flocks, and hardly possess any organisation as a separate body. 'The Eastern Church has never ruled that religious light and instruction are confined to the clergy.' And its strength 'reposes not so much on the power and influence of its clergy, but on the independent knowledge and manly zeal of its laity' (Stanley). The Eastern Church has become inactive since its subjection to Turkish rule. It is not a missionary church, and it abstains from proselytism. On the other hand, it never was intolerant, and its history has not been disgraced by persecutions, inquisition, or a St Bartholomew's massacre.

Relations with the Reformed Churches.—Owing to these reasons the early reformers turned their eyes to the Eastern Church in hope of support and eventual union. Melanchthon was the first to address a letter to the patriarch Joseph of Constantinople, through a Greek deacon, Demetrius Mysus, who visited Germany in 1558. Another Lutheran embassy, of a more formal character, headed by the well-known Tübingen divines Jacob Andreæ and Martin Crusius, visited Constantinople during the patriarchate of Jeremias (1576–81). Both missions were equally devoid of immediate practical results. But in the following century the celebrated Cyril Lucaris, a native of Crete, was educated in Germany, and was there imbued with the tenets of the Reformers. On assuming the patriarchate of Alexandria first (1602) and then of Constantinople (1621) he opened negotiations with the Calvinists with a view to union and the reform of the Greek Church; he corresponded with the English Archbishop Abbot and with Laud, and he presented the Alexandrian Codex (q.v.) to Charles I.; and in 1629 he issued a confession of faith of a decidedly Calvinistic tendency. But his efforts were bitterly opposed by the intrigues of the Jesuits, who brought about his deposition five times after successive reinstate-

ments in the patriarchal chair, and are supposed finally to have instigated his murder by the Turks. The innovations contemplated by Lucaris called forth a doctrinal declaration signed by the patriarchs of Constantinople, Alexandria, and Antioch, and defining the differences between the Greeks and the Reformers. This exposition was later (1672) adopted at a synod held at Jerusalem. But within our time the conciliatory spirit which animates these two branches of Christianity has found expression in practical measures of closer intercourse. In February 1872 the Greek bishop of Patras was present and delivered his benediction at the laying of the foundation-stone of an Anglican church in that town. And when later Lycurgus, the learned Archbishop of Syra and Tinos, and the Archbishops of Corfu and of Cyprus, visited England, they each attended Anglican services, and delivered their benediction in Anglican churches. But the most notable advance towards 'intercommunion' was made in 1859, and again in 1874, when the House of Convocation appointed a committee 'to establish such relations between the two communions as shall enable the laity and clergy of either to join in the sacraments and offices of the other without forfeiting the communion of their own church.' As a first step towards this end the patriarch of Constantinople issued an encyclical enjoining his clergy to bury deceased members of the Anglican Church in orthodox burial-grounds, and to celebrate their funeral rites with prayers taken from the funeral office of the orthodox church.

Sects.—The early theological controversies within the Greek Church itself, resulting in sectarianism, differ in this respect from the secessions from the Roman Church—that in the West the protest was directed mainly against abuse and ultramontanism, whereas in the East objections have always been raised against what was deemed innovation.

All the branches of the Eastern Church receive the first two councils, those of Nicea and Constantinople. But these two only are admitted by the *Chaldeans*, the earliest of Eastern separatists, whose dispute related to the meaning of *ἐνανθρώπησις* ('incarnation'). This doctrine gave rise to two distinct and opposed theories. The one accepted complete union of the human and the divine nature of Christ, and formed the belief of the *Monophysites*. The other maintained a separation of the two natures, so as to deny their co-existence in one person, and rejected the term *Theotokos* as applied to the Virgin Mary. Such were the tenets of Nestorius, whom the third Council of Ephesus (431) condemned, and after whom the Chaldeans are also called *Nestorians*. This sect spread rapidly throughout the interior of Asia, and became active in missions, not only to the neighbouring Persians and Indians, but to the Bactrians and Huns, as far north as the Caspian, to Samarkand and the very confines of China, and to Socotra, Ceylon, and the Malabar coast in the south. In this last locality a remnant of the former growth and power of this church still exists. They are the *Christians of St Thomas*, so called either from the apostle, or more probably from a Nestorian missionary of that name. Mussulman persecution, however, and the inroads of eastern barbarians have weakened, and at one time had almost annihilated, the Nestorians, who are now found principally in Kurdistan, and who believe themselves to be the lost tribes of Israel. Their sacred city is Edessa, the reputed birthplace of Abraham, and their 'catholikos' or primate assumes the title of 'Patriarch of Babylon,' his seat having been successively removed thence to Bagdad, Mosul, and Julamerk (or Giuliamerk), where he now resides. The Nestorian patriarch is the only Eastern prelate who may marry.

The tenets of the *Monophysites* were condemned by the fourth œcumenical council of Chalcedon (451), which established that Christ is to be acknowledged in two natures, 'indivisibly and unchangeably.' On this the larger portion of Syrian and Egyptian Christians, who had accepted the three former councils, seceded from the church, and soon broke up into three minor communities, largely through the influence of nationality.

In Syria the Monophysites were called *Jacobites*, from James the Apostle as they pretend, but more probably from Jacobus Baradeus, the Syrian heresiarch, since the name is equally applied to the other churches of the sect. The patriarch of the Syrian Jacobites bears in succession always the hallowed name of Ignatius, and resides at Diarbekir (the ancient *Amida*), on the right bank of the Tigris. The country beyond was originally under the charge of the 'Maphrian ("fruit-bearer") of the East,' so called from the fact that his was primarily a missionary see—it is now established at Mosul. This church, like the Nestorian, was formerly widespread and flourishing, extending to more than a hundred bishoprics, of which but five now survive.

The Jacobites of Egypt are better known under their national designation of *Copts* (q.v.), and form the great majority of the Christian population of northern Africa, as well as the most civilised of its native races. They have intercommunion with the Jacobites of Syria. Their patriarch, who takes his title from Alexandria, but resides at Cairo, claims jurisdiction over Jerusalem, Egypt, Nubia, Abyssinia, and the Pentapolis. He is elected by the body of bishops from candidates nominated by the four convents which possess this right. He alone has power of ordination, which is conferred, not by imposition of hands, but by the act of breathing.

A third branch of the great Jacobite communion is the *Ethiopian Church* in Abyssinia, where Christianity was first introduced in the 4th century by missionaries from Alexandria. The 'abouna' or metropolitan is, under the nominal supremacy of the Coptic patriarch at Cairo, primate of the Abyssinian Church, which presents an extraordinary combination of Christian and Jewish observances. Both baptism and circumcision are deemed necessary; both the Sabbath and Sunday are observed; polygamy is permitted, though not common; and the flesh of swine is forbidden. The old controversies as to the nature of Christ still continue in Abyssinia; and Pilate, because he washed his hands of the blood of Christ, is canonised by the Ethiopian Church.

The *Armenian Church*, which is often considered Jacobite, because it also receives only the first three councils, is, in all essential points, much more akin to the Church of Constantinople; and, indeed, the non-united section of the communion call themselves 'Orthodox.' The absence of the Armenian delegates from the Council of Chalcedon was due to the internal disorders of their country, but they were definitely separated from the Greek Church in 552. The Armenians were converted to Christianity by Gregory the Illuminator, and are therefore often called *Gregorians* (see ARMENIA). They, of all Christian churches, include as canonical Old Testament books the 'History of Joseph and Asenath,' and the 'Testament of the Twelve Patriarchs;' and in the New Testament the 'Epistle of the Corinthians to St Paul,' and 'Third Epistle of St Paul to the Corinthians.'

The decisions of the sixth œcumenical council held at Constantinople (680) resulted in the secession of the *Monothelites*, whose tenets as to the one will of Christ that council condemned. They included the Christian population of the Lebanon, who have since been better known as *Maronites*,

from St Maro, as they allege, the Syrian anchorite of the 5th century, after whom the famous convent near Cyrus is named, but more credibly from John Moro, their first patriarch in 701. Their primate is the patriarch of Kanobin. In the 12th century, however, by the influence of the Crusaders, the Maronites submitted (1182) to the Roman Church, of which they now form an integral part.

It is essential to observe that in each of the sects and churches so described there are, almost without exception, three divisions, resulting from the influence respectively of old traditions, nationalistic proclivities, and the Jesuit Propaganda. In each of these Eastern communions one should therefore distinguish (1) the 'Orthodox' section, with decided leanings towards the church of Constantinople; (2) the 'National' section, which maintains the independence of each particular heresy; and (3) the 'United' or 'Catholic' section, which acknowledges the supremacy of the pope.

Uniats or *United Greeks.* This last category forms an important fraction of the Greek Church itself. The fall of the empire facilitated the intrigues of the Roman Propaganda, which, especially after the Reformation, endeavoured actively to secure the submission to Rome of isolated Greek communities in the East; while, in the West, the influence of Catholic governments was brought to bear, to the same end, on the scattered Greek colonies, and on the outlying portions of the Greek Church. Thus, the numerous Greek and Albanian refugees from Epirus, who had settled in Sicily and southern Italy, were soon compelled to succumb; as also the indigenous orthodox populations in Austria and Poland—i.e. the Roumanians in Transylvania and eastern Hungary, and the Ruthenians in Galicia and Little Russia. The Polish Greeks, however, who had become 'Uniats' in 1590, reverted, for the most part, to the Russian Church in 1839. It is difficult to state exactly to what degree union has thus been attained. The primary, and in most cases, the only condition, was submission to papal supremacy; all else—clerical matrimony, communion in both kinds, church discipline, rites, and liturgy—being allowed to remain Greek. But when circumstances were favourable, more stringent conditions were gradually imposed. And therefore the 'Unia,' as the pact is styled, is not uniform in aught else but the unremitting efforts of the Propaganda to efface the individuality of these dismembered churches.

The Four Patriarchates.—The Mohammedan invasion submerged and curtailed the area, especially in Asia and Africa, over which the Eastern Church had spread; and the other vicissitudes to which reference has been made modified from time to time the extent of that area. Still, the four patriarchates claim jurisdiction within their original boundaries, with the exception of the independent states which were successively emancipated from Turkish rule.

The patriarchate of Constantinople includes the whole of European Turkey, Asia Minor and Pontus (Trebizond), and all the islands. The patriarchate of Antioch includes Syria, Phœnicia, Isauria, and Cilicia. This patriarchate, which at one time extended its influence to India and as far as China, has suffered most from the spread of Mohammedanism. The patriarchate of Jerusalem includes the whole of Palestine, and, prior to the Saracenic conquest, was one of the most flourishing, although the one established last (451). The patriarchate of Alexandria, once the most powerful and important, has shrunk, since the Mussulman occupation of Egypt, into the narrow limits of the see of that particular city.

The archiepiscopal see of Cyprus, which formed part of the patriarchate of Antioch, was raised to an independent position by the Council of Ephesus (431), and its primate, though inferior in rank to the patriarchs, has precedence over all other archbishops. He enjoys the exceptional privilege of affixing his signature in red ink.

The church of Constantinople is known as 'the Great Church' (Μεγάλη Ἐκκλησία), from its ancient pre-eminence as the see of the *œcumenical* patriarch—a title conferred by the emperor on John the Faster (587) against the remonstrances of Gregory I. The Church of Antioch claims to have been founded by St Peter, and that the similar pretensions of Rome are at once more recent and less certain. The name of Christians was first given to the believers in Antioch, and to its chief pastor alone the title of patriarch belongs by right. The patriarch of Alexandria is the first Christian primate who was styled 'pope.' His other title of 'œcumenical judge' arises from the right which the early Alexandrian Church possessed of fixing the period of Easter.

National Churches.—The authority which the Byzantine emperors exercised over the government of the Greek Church passed, with Constantinople, to the sultans. After the massacre which followed the capture of the city, and in which the patriarch had fallen with the emperor, Mohammed II. installed as patriarch George Gennadius, a Greek monk, renowned for his piety no less than for his scholarship, for which he was surnamed Scholarius. The courage and persuasiveness with which he expounded before the sultan the tenets of Christianity induced Mohammed to confer certain privileges on the patriarchate, enabling it to exercise a measure of authority over the orthodox church within Turkish dominions. This first concession constitutes to this day the charter regulating the relations of the church to the Porte. The patriarch is elected by a synod of bishops, but the candidate must be approved of by the Porte, which also issues firmans enabling the bishops to act within their dioceses. This gives to Turkish authority so effectual a control over the church, that its having survived at all is a proof of extraordinary vitality. But the abuse and scandal consequent upon the exercise of that authority was such as to make it the interest, both of the patriarchate and of the independent states which recognised its spiritual guidance, not to continue under a jurisdiction subjected to the sultan's will. Fortunately the constitution of the Eastern Church favoured the creation of autocephalous churches, which, while enjoying a separate internal administration, could remain bound to the Church of Constantinople and to each other by the unity of faith and dogma.

The *Church of Russia*, which alone of eastern churches presents historical continuity, was established when in 988 Anne, sister of the Emperor Basil, was wedded to Prince Vladimir, who was thus converted, and who at the same time ordered all his people at Kieff to be baptised in the Dnieper by the Greek clergy. From that time the Christian civilisation of Russia was Greek, from the alphabet which the Greeks adapted to the Slavonic language to the baptismal names of emperors and peasants alike; and Russia recognised this debt of gratitude by the powerful protection she has extended to the eastern Christians, amongst whom she is consequently known as 'Holy Russia.' The metropolitan, residing first at Kieff and later (1320) in Moscow, was subject to the patriarch of Constantinople. In 1582, however, with the concurrence of the whole church, the patriarch Jeremiah II. raised the Russian see to a patriarchate, still dependent on Constantinople. This dependency continued till the time of Peter the Great, who in 1700, again with the sanction of the whole body of eastern

patriarchs, suppressed the patriarchate of Moscow and confided the government of the Church of Russia to a synod composed of five or six bishops and a number of lay dignitaries, all appointed by the czar, who remained supreme head of the church. In Russia there are several dissenting sects.

The *Church of Georgia* (ancient Iberia) dates from the time of Constantine, when Nina, a Christian slave, converted the king and his people. It first formed part of the patriarchate of Antioch, and was subsequently transferred to that of Constantinople. But since the annexation of Georgia to the Russian empire the archbishop of Tiflis has been a member of the Russian synod.

The *Montenegrins*, who never acknowledged the suzerainty of the sultan, did not admit the jurisdiction of the Constantinopolitan patriarch. They were governed, since 1697, when they formally proclaimed their independence, by a 'Vladika' or prince-bishop of their own, chosen from the family of Petrović, and who exercised both spiritual and temporal power. In October 1851, however, Danilo I., on succeeding his uncle, the last Vladika, abandoned his ecclesiastical functions, and assumed the temporal title of hospodar or prince. The bishops of Montenegro have since been consecrated by the Russian synod.

In *Austro Hungary* there are over three millions of orthodox Christians, principally of the Servian and Roumanian nationality, besides four million Uniats. Of the former, who are there known as Byzantine Greeks, about half a million are scattered through the Austrian dominions, and the rest are in Hungary, with two archbishops (Carlowitz and Hermannstadt) and eight bishops, six in Hungary proper, and two in Croatia. The archbishops exercise their jurisdiction under Austria.

In *England* a Greek Church has existed since the middle of the 17th century. The periodical emigrations of Greeks to the west, consequent upon each fresh recrudescence of Turkish tyranny, resulted in the formation of a Greek colony in London, which must have been considerable both in numbers and position; for we find that many young Greeks were sent to Oxford, as a rule to St John the Baptist (Gloucester) Hall, where they replaced the Irish, who, after the establishment of Trinity College, remained in Dublin. A certain Nathanael Conopius, however, was at Balliol, where he first taught the Oxonians to make coffee, and whence he was expelled by the Puritans in 1648. When the Archbishop of Samos, Joasaph Georgirenes or Georgirenes, had to flee from his diocese, and arrived in England about 1666, he found amongst his co-religionists in London Daniel Bulgaris as priest, but there was no church. He therefore applied to the then Bishop of London, Henry Compton, who befriended him, and who with other English bishops collected a small fund, to which even King Charles II. is said to have contributed, for the erection of a Greek church on a piece of land in Crown Street, Soho Fields, given by the parish of St Martin-in-the-Fields. (See *A Description of the Present State of Samos, Nicaria, Patmos, and Mount Athos*, by Joseph Georgirenes, Archbishop of Samos; Lond. 1678.) This church, which was dedicated to St Mary the Virgin's Sleep, is still extant, and a marble tablet over the west door bears an inscription in Greek recording these facts, as well as the names then given to Greek Street and Compton Street in the same neighbourhood commemorate those events. The church, which is the one represented in Hogarth's well-known picture of 'Noon,' soon passed to the French Protestant refugees; it was subsequently fitted up as a meeting-house for the Rev. John Rees, and in 1850 it was reconsecrated as an Anglican church, to St Mary the Virgin (*Ecclesiologist*, xi. 120). A copy (made about 1760) of the original register, which seems to have perished, of that first Greek community exists in the chapel of the Russian embassy in London (Welbeck Street), and records the fact that when the Archimandrite Gennadius was priest in London, both the church and the community had become 'Greco Russian.' After the death of Gennadius (February 3, 1737), who was buried in St Pancras' Churchyard, the entries in the register record more and more frequent marriages between English and Greeks, who thus appear to have been absorbed by the indigenous element, their anglicised names which are still to be met with (Rodos, Pamphylos, Lesbos, &c.) confirming the fact. But in the beginning of the 19th century another Greek community sprung up in London by the arrival in 1818 from the island of Chios of three out of the five brothers Ralli, who founded the great firm of that name, and who were soon followed by others of their countrymen. They at first met at a chapel in one of the houses in Finsbury Circus, and in 1847 built a church in London Wall. As the community increased in riches and in numbers, this modest building was replaced in 1879 by a magnificent Byzantine church in Moscow Road, Bayswater, built after the model and bearing the hallowed name of 'Hagia Sophia.' Flourishing Greek churches exist also in Liverpool and in Manchester.

In the *United States* there are a Greek church in New Orleans and a Russian in San Francisco.

The *Church of Greece* offers a strong instance of the causes which militate against dependence upon a jurisdiction subject to the will of the sultan. The Greek struggle for freedom, which carried with it the active sympathy of the whole Greek nation, was, at the dictate of the sultan, put under the ban by the patriarch Gregorius, who, nevertheless, was soon afterwards hanged for complicity in the national cause. In the second year of the war the Assembly of the Greeks at Epidauros proclaimed (1822) the orthodox church as church of the new state, and the Royal Decree of 15-27th July 1833 organised the church on a plan similar to that of Russia, with a synod of five bishops, presided over by the Archbishop of Attica. A lay government commissioner attends the deliberations, but may not vote. The synod is the supreme ecclesiastical tribunal, and elects bishops under the confirmation of the crown. The clergy are excluded from all participation in politics, and are not eligible to sit in the legislature. In 1850 the patriarchate of Constantinople acknowledged the independence of the Church of Greece, which has already rendered to the other Greek-speaking churches great services in the education and training of priests. Of the large number of convents which existed in Greece, many were destroyed during the war of independence, and others have been utilised for educational purposes. Of those still extant the Meteora in Thessaly and Mega Spileon in the Peloponnesus are the most notable for extent and historical interest.

The *Church of Servia* existed, under the early Servian kings, as an independent church, with a patriarch at Belgrade (1300). The Turkish conquest disorganised that church, and, in 1679, 37,000 Servian families emigrated to Hungary under Arsenius Czernowitz, and established the see of Carlowitz. In 1765 the Servian patriarchate was suppressed by the Turks, and the Servian Church placed under the jurisdiction of the patriarch of Constantinople. When the semi-independence of Servia was achieved under Kara George (see CZERNY), in 1810, the government of the church was again transferred to the metropolitan of Carlowitz. Finally, in 1830, Servia declared her church autocephalous under the Bishop of Belgrade.

The *Church of Roumania* is the outcome of more violent and unfilial proceedings. The ecclesiastical administration of the two Danubian principalities of Moldavia and Wallachia was originally vested in the metropolitans of Jassy and Bucharest respectively, acting under the patriarch of Constantinople. The clergy in both principalities were almost exclusively Greek, few Roumanians having at that time either education or vocation for clerical life. The numerous conventual institutions in which they were assembled possessed immense landed estates, the bequests of Greek merchants and benefactors, who, through many generations adopted this as the only safe mode of endowing philanthropic and educational institutions within the reach of Turkish rule. Those estates, as well as others of an even greater extent and value in Russian Bessarabia (the revenues from which were sequestrated in 1873), furnished to the patriarchates of Constantinople and Jerusalem almost the only means of maintaining schools and hospitals throughout Turkey. When, however, the Moldo-Wallachians awoke to a sense of independent nationality and proclaimed the union of the two principalities under Alexander Couza (December 23, 1861), one of the first acts of the new Roumanian government was to sequestrate the Greek monastic property and declare the Roumanian Church autocephalous. It is now governed by the primate of Roumania, whose see is at Bucharest, with an archbishop of Moldavia at Jassy, and six bishops.

The *Bulgarians*, even before their political independence, had organised, for political purposes, a church of their own under an exarch. The Turkish government, anxious to foment disunion between its Christian subjects, encouraged the forcible appropriation by the Bulgarians of Greek churches and schools, and sanctioned their ecclesiastical policy. As, however, canon law does not admit of the co-existence within the same diocese of two separate churches of the same faith, the patriarch of Constantinople signified his readiness to acknowledge the independence of the Bulgarian exarchate, if its territorial limits were clearly defined, and if the exarch designated his see within those limits. This the Bulgarians refused to do, their avowed object being to extend their political influence through the exarchate, not only in mixed Græco-Bulgarian districts, but even over purely Greek dioceses. A general synod of the four patriarchs was therefore convened (1873) at Constantinople, and the excommunication of the exarchate followed. The Russo-Turkish war resulted in 1878 in the constitution of an independent Bulgarian state; but its ecclesiastical head, the Bulgarian exarch, continues to reside at Constantinople and to claim jurisdiction over the Bulgarians in Thrace and northern Macedonia also. He does not concede, however, to the patriarch of Constantinople a similar right over the Greeks in Bulgaria. The excommunication of 1873 is still maintained.

The total number of adherents of the Greek Church it is impossible to state precisely; the following are the only available reliable figures:

Orthodox Greeks.	
Russia	61,940,000
(Of these about 1½ million are dissenters.)	
Austria	493,000
Hungary	2,434,000
Greece	2,200,000
Roumania (about)	5,250,000
Bulgaria	2,007,000
Eastern Roumelia	734,000
Servia	1,939,000
Montenegro	232,000
Turkish Empire (approximately)	7,000,000
	234

Uniats.	
Russia	55,000
Austria	2,536,000
Hungary	1,500,000
Turkish Empire (approximately)	1,000,000

Sects.	
Nestorians	270,000
Jacobites	350,000
Maronites	250,000
Armenians –	
In European Turkey	380,000
In Asiatic Turkey	760,000
Abyssinians (about)	1,250,000

Literature. The first portion of this article is founded on Dean Stanley's admirable *Lectures on the History of the Eastern Church*, which have served as a basis to later treatises on the same subject. But the following authorities may also be consulted.—(1) *History*: Gibbon; Robertson; Gieseler's *Ecclesiastical History*, J. M. Neale, *History of the Holy Eastern Church*.—(2) *Controversies*: Dorner, *History of the Doctrine of the Person of Christ* (in Clark's translations); Swainson, *The Apostles' and Nicene Creed*; Walch, *Historia Controversiæ de processu Spiritus Sancti*; J. H. Newman, *The Arians of the Fourth Century*. W. Palmer, *Dissertations on Subjects relating to the Orthodox Communion*.—(3) *Councils and Canon Law*: Hefele, *History of the Councils* (Clark's translations); Photius, *Nomocanon* (Paris, 1615); G. A. Rallı and M. Potlis, Συνταγμα των θειων και των ἱερων κανονων (Athens, 1852-56).—(4) *Liturgy, Ceremonies, &c.*: E. Renaudot, *Liturgiarum Orientalium Collectio* (Paris, 1715-16); J. Goar, *Eucologium sive Rituale Græcum* (1647); H. A. Daniel, *Codex Liturgicus Ecclesiæ Orientalis* (1853); J. M. Neale and R. F. Littledale, *The Liturgies* (trans. 1869); H. A. Greek-fire, a composition supposed to have been of pounded resin or bitumen, sulphur, naphtha (the principal ingredient), and probably nitre, with which, from about 673 A.D. onwards, the Greeks of the Byzantine empire were wont to defend themselves against their Saracen adversaries. The accounts of its effects are so mingled with obvious fable that it is difficult to arrive at any just conclusion as to its power; but the mixture appears to have been highly inflammable, and to have been difficult to extinguish; though the actual destruction caused by it was hardly proportionate to the terror it created. It was poured out, burning, from ladles on besiegers, projected out of tubes to a distance, or shot from balistæ, burning

on tow tied to arrows. The invention of this material has usually been ascribed to Callinicus of Heliopolis, and to the year 668 A.D. At Constantinople the process of making Greek fire was kept a profound secret for several centuries. The knowledge, however, of its composition gradually spread; and the use of it spread to the West. Subsisting for some time concurrently with gunpowder, it gradually died out before the advances of that still more effective competitor. Combustibles with a similar aim were used at the siege of Charleston in 1863, composed of sulphur, nitre, and lampblack; and naphtha in shells was also tried. The petroleum bombs of the Paris Commune of 1871 corresponded more nearly to Greek-fire than does gunpowder.

Greeley, HORACE, American journalist, described by Whittier as 'our later Franklin,' was born at Amherst, New Hampshire, February 3, 1811. His father was a small farmer, always poor; and Horace, the third of seven children, after acquiring the rudiments of education at a common school, entered a printing-office as an apprentice (1826), at East Poultney, Vermont, and rose so far as to assist in editorial work on the *Northern Spectator*. Released from his apprenticeship in 1830 by the suspension of this paper, he worked for some time as a journeyman printer in various country offices, and in August 1831 made his way to New York with ten dollars in his pocket, and his stick and bundle over his shoulder. He had difficulty in obtaining work at first owing to the oddity of his appearance. For fourteen months he worked as a journeyman printer, when he started business along with a fellow-workman, and in 1834 commenced the *New Yorker*, a literary weekly paper, for which he wrote essays, poetry, and other articles. His first marked success, however, was the *Log Cabin*, a Whig campaign paper which contributed largely to bring about the election of General W. H. Harrison to the presidency in 1840, and which was afterwards continued for some months. On April 10, 1841, he published the first number of the *New York Tribune*, of which he was the leading editor till his death. In the same year he merged his weekly papers, the *Log Cabin* and the *New Yorker*, in the *Weekly Tribune*, which rose to have a large circulation in the rural districts. The *Tribune* has been an earnest advocate of temperance, co-operation, international copyright, a protective tariff, the abolition of slavery and capital punishment, and other reforms; was at first Whig, then anti-slavery Whig, and was finally recognised as the organ of the extreme or radical Republican party. Greeley advocated and adopted to some extent the social theories of Fourier. Among the contributors whom he gathered around him were such well-known writers as G. W. Curtis, W. H. Fry, C. A. Dana, Margaret Fuller, and Bayard Taylor; while he was amongst the first American journalists to recognise the genius of Dickens, Bret Harte, and Swinburne. His business faculty was indifferent, and he was easily imposed upon by impecunious people and adventurers.

In 1848 Greeley was elected to congress by one of the districts of New York, to fill a vacancy, but failed in his congressional career by agitating an unwelcome reform in the mileage payments to members. In 1851 he visited Europe, and was chairman of one of the committees of the Great Exhibition. He was again in Europe in 1855. His aspirations to political position were defeated by the more conservative party leaders, and he, in turn, is supposed to have helped the nomination of Lincoln instead of Seward in 1860. On the secession of the southern states from the union, Greeley at first advocated their right to secede, as being in accordance with the principles of the Declaration of Independence; but when the war began he became one of its most zealous advocates, rival newspapers alleging that he caused the premature advance that resulted in the defeat of the government troops at Bull Run, July 21, 1861. He published an impressive anti-slavery appeal in the *Tribune*, entitled 'The Prayer of Twenty Millions,' which, besides making a profound impression, drew from Lincoln a remarkable letter; and within a month thereafter the emancipation proclamation was issued. After Lee's surrender he warmly advocated a universal amnesty; and his going to Richmond and signing the bail-bond of Jefferson Davis awakened a storm of public indignation. In spite of oratorical defects Greeley was a good and popular speaker. In religious faith he was a Universalist. In 1872 he was an unsuccessful candidate for the presidentship, receiving 2,834,079 of the popular vote, as against 3,597,070 for General Grant; the strain proved too great for him, and he died 29th November of the same year.—A town in northern Colorado, which he helped to colonise, was named Greeley. Greeley's works include *The American Conflict* (2 vols. 1864-66); *Recollections of a Busy Life* (1868); *Essays on Political Economy* (1870); *What I know of Farming* (1871). There are Lives by Parton, Reavis, and Ingersoll, and a memorial volume (1873).

Greely, ADOLPHUS WASHINGTON, Arctic explorer, was born at Newburyport, Massachusetts, 27th March 1844. He served as a volunteer through the war of 1861-65, and shortly after its conclusion entered the regular army as lieutenant, and in 1868 was placed on the signal service. In 1881 he was selected to conduct the American expedition to the head of Smith Sound, for the purpose of carrying on observations in pursuance of the international scheme arranged at Hamburg in 1879. He and the survivors of his party were rescued in June 1883, when at the point of perishing from starvation, after spending three winters in the Arctic north. Their sufferings were so extreme that some of the party had even been reduced to eating the bodies of the dead. Lieutenant Lockwood of this expedition travelled to within 396 miles of the geographical pole, the farthest point north hitherto reached. In 1887 Greely was appointed chief of the signal service, at the same time being gazetted brigadier-general. In 1886 he published *Three Years of Arctic Service*. See also W. S. Schley, *The Rescue of Greely* (1885).

Green, JOHN RICHARD, historian, was born at Oxford in December 1837, and had his education at Magdalen College School and at Jesus College there. The atmosphere of his native city had filled him, while still a boy, with sympathetic interest in the past, but the reading of Gibbon at sixteen shaped him into a historian. His earliest writing was a striking series of papers in the *Oxford Chronicle* on 'Oxford in the last Century.' He took orders, and was in succession curate and vicar of two East-end London parishes, where he gave himself with characteristic unselfishness and enthusiasm to the pressing social problems around him. Yet he snatched time from his busy life to pursue his studies and to contribute historical articles to the *Saturday Review*. In 1868 he became librarian at Lambeth, and next year he was struck down with an attack of consumption, a disease which darkened all his remaining years, and made any kind of active work hereafter impossible to him. Yet he toiled on with noble and uncomplaining heroism, and at last the instant popularity of his *Short History of the English People* (1874) justified the patience and endurance with which he had laboured to bring his work up to his own ideal.

It was the first complete history of England from the social side, and showed at once marvellous grasp of the real significance of great historic movements, fine sense of historical perspective and proportion, and startling dramatic force in the realisation of men and motives; while its style was fluent and unforced, yet ever vigorous and effective. His vast yet intimate topographical and antiquarian knowledge of England added life and truth to the narrative to a degree hitherto unexampled among English historians. The work attained an unparalleled success, as many as 150,000 copies having been sold within fifteen years. He issued also a larger and independent edition of the work as *A History of the English People* (4 vols. 1877–80); *Stray Studies from England and Italy* (1876), the fruit of his winters in Capri; and a *Short Geography of the British Islands* (1879), written in conjunction with his wife, and lightened up by his genius for topography. In 1879 he received the degree of LL.D. from the university of Edinburgh. He brought out in 1880 a selection of essays of Addison, with an introduction. He also prepared for Macmillan's educational series a selection of readings from English history, in three parts, and was general editor of their well-known series of historical and literary primers. In 1881 his feeble health finally gave way, yet he continued to the last his heroic struggle against hopeless disease, publishing in 1882 his *Making of England*, and leaving *The Conquest of England* to be edited by the pious care of his widow. His death took place in March 1883. His last two books are fragments of a projected history of England to the Conquest. See the admirable memoir prefixed to the 1888 edition of the *Short History*, by his wife (born 1849), who with Miss Norgate edited a richly illustrated edition of the *Short History* 3 vols. 1892–93). Mrs Green is the author of *Henry II.* (1888) and of *Town Life in the 15th Century* (1894).

Green, Mary Anne Everett, *née* Wood, was born in 1818 at Sheffield. She received an excellent education, and her culture was promoted by James Montgomery, the 'Bard of Sheffield.' In 1841 she removed with her parents to London, where in 1845 she married Mr G. P. Green, artist. Having free access to libraries and MS. collections, she edited *Letters of Royal and Illustrious Ladies* (1846); *The Diary of John Rous* (Camden Soc. 1856); *Letters of Queen Henrietta Maria* (1857). By appointment of the Master of the Rolls she calendared the papers of the reign of James I. (1857–59), and those of Charles II. (1860–68). She next completed the calendar of the state papers of Queen Elizabeth, with addenda from Edward VI. to James I. (6 vols. 1869–74), and edited the papers of the Commonwealth (12 vols. 1875–88), besides contributing to periodical literature. She died 1st November 1895.

Green, Thomas Hill, philosopher, was born at Birkin in the West Riding of Yorkshire, where his father was rector, April 7, 1836. At fourteen he was sent to Rugby, then under Goulburn's mastership, and in October 1855 he entered Balliol College, Oxford, where he was profoundly influenced by Jowett, Conington, and C. Parker. In 1859 he took a first-class in the school of *litteræ humaniores*, later a third in law and modern history, and in November 1860 was elected to a fellowship in his college, and re-elected in 1872, becoming also its first lay tutor in 1866. He married a sister of John Addington Symonds in 1871, was appointed in 1877 to be Whyte's professor of Moral Philosophy, and died after an illness of but eleven days, March 26, 1882. By his will he left £1000 to the university for a prize essay in the department of moral philosophy, £1000 to found a scholarship at the Oxford High School for boys, and £3500 to Balliol College for the promotion of higher education in large towns. Green's singularly noble character, contagious enthusiasm, and rare union at once of profundity and subtlety in philosophical speculation with strong interest in practical life and in social questions, drew around him a school of disciples that included many of the best men of his time at Oxford. His philosophy grew out of Hegelianism, but was strikingly original and vital in its form, no less than in its applications to the duties of everyday life. Thus, popular education and the spread of temperance were two objects that lay near his heart, and he gave himself with earnestness to the business of the Schools Enquiry Commission of 1864–66, and of the Oxford Schoolboard (1874), and helped to force on the Bribery Commission at Oxford to purge the political conscience of its citizens; because the natural conclusion of his philosophy was towards an association of individuals as homogeneous co-factors in the eternal spirit; the supreme and comprehensive rule of life being the law of love which binds men at once to human society and to God, society itself the necessary condition for the development of personality, and religion but the highest form of citizenship. He had written but little before he contributed in 1874 his masterly introduction to the Clarendon Press edition of Hume's *Treatise on Human Nature*. His *Prolegomena to Ethics*, left incomplete at his death, was edited by A. C. Bradley (1883), and two unusually pregnant 'lay-sermons' by Arnold Toynbee in the same year. His scattered essays in *Mind* and elsewhere were collected and published as the *Works*, by R. L. Nettleship (3 vols. 1885–88; 2 vols. philosophical; 3d, miscellanies and a memoir). His lectures on *The Principles of Political Obligation* appeared in 1895. See Fairbrother, *The Philosophy of T. H. Green* (1896).

Greenbacks. During the civil war in America, from 1861 to 1865, the immense expenditure of the United States government led to the printing of an unprecedented number of bank-notes, bonds, and currency papers of various kinds. These documents, from the colour presented by them, or some of them, obtained the name of *greenbacks*, a designation which came to be loosely used for all United States bank-notes. The first 'demand notes' were issued in August 1861; the first greenbacks proper were of date March 10, 1862. Soon forged notes and bonds were in circulation; but by degrees a large establishment was organised at Washington, under the immediate control of the Secretary to the Treasury, and the precautions used were such as almost completely to baffle forgers. The paper currency, whose value had fluctuated greatly, was declared convertible into coin on 1st January 1879, and specie payments completely resumed. For the manufacture of the notes from first to last, see Bank-Notes.

The great inflation of the currency during the war, along with the heavy demand for all sorts of farm-produce, brought a period of prosperity to the western farmers, which ended with the war itself. In 1867–68 the 'Ohio idea,' as the demand for an irredeemable paper currency was called, found much favour with the Democrats, especially in the West; and in 1874 an independent Greenback party held a convention at Indianapolis and formulated its demands. In 1876 the party nominated Peter Cooper (q.v.) for the presidency; he received ·97 per cent. of the popular vote. In 1880 the Greenback candidate was James B. Weaver, who polled 3·33 per cent.; and in 1884 General B. F. Butler was put forward, and received 1·33 per cent. of the popular vote. None of the candidates

ever received electoral votes. In 1888 there was no Greenback candidate, and of late the two sides on the currency question have been championed by B. Harrison (q.v.) and Mckinley (q.v.).

Green Bay, county-seat of Brown county, Wisconsin, is at the head of Green Bay, in Lake Michigan, and at the mouth of Fox River, 65 miles NNE. of Fond du Lac. It exports lumber and grain, and has a handsome Roman Catholic cathedral. Pop. 1890, 9069.

Greenbush, a town in New York State, on the other side of the Hudson from Albany (q.v.), so that it is sometimes called East Albany. Pop. 1890, 7287.

Green Cloth, Board of, a committee of the royal household of England attached to the department of the lord steward (see STEWARD), who presides over its deliberations. Its duties are to examine and pass all the accounts of the household, and to correct all offenders within the verge or jurisdiction of the palace, which extends to two hundred yards beyond the gates.

Greene, NATHANAEL, a famous American general, was born 27th June 1742, at Warwick, Rhode Island. His father was a leading preacher among the Quakers, and educated his son very simply, training him from childhood to work on his farm, and at his forge and grist-mill. By his own perseverance, however, Nathanael the younger acquired considerable knowledge of ancient and English history, geometry, law, and moral and political science; he was also fond of reading books upon war. In 1770 he was chosen a member of the Rhode Island Assembly, and, to the great scandal of his fellow Quakers, was among the first to engage in the military exercises preparatory to resisting the mother-country. In 1774 he enlisted as a private, and in 1775 he was appointed to the command of the Rhode Island contingent to the army around Boston, with the rank of brigadier-general. Promoted to be major-general, he distinguished himself at the engagements of Trenton and Princeton. At the battle of the Brandywine he commanded a division, and by his skilful movements saved the American army from utter destruction; and at Germantown he commanded the left wing, and skilfully covered the retreat. In 1778 he accepted the office of quartermaster-general, retaining the right to command in the field. In 1778 he fought at Monmouth Court-house; in 1780 he foiled Clinton at the Rahway bridges, was president of the board that condemned André, and, having resigned the quartermaster-generalship owing to the delays of congress in providing supplies, was appointed to Arnold's post at West Point.

In December 1780 he succeeded Gates (q.v.) in the command of the army of the south. Gates had just been completely defeated by Cornwallis, and Greene found the army in a wretched state, without discipline, clothing, arms, or spirit. By dint of great activity he got his army into better condition, and in January 1781, one of his lieutenants having nearly annihilated an English detachment, and this having drawn upon Greene the whole army of Cornwallis, much his superior in numbers, he made a masterly and successful retreat. On 15th March, having drawn Cornwallis more than 200 miles from his base, he forced on him a battle at Guilford Court-house, which resulted in a victory for the British, but one so costly that Greene was allowed to pass unmolested into South Carolina. The inland portions of this state and Georgia were rapidly reconquered, and fort after fort reduced, until, at the battle of Eutaw Springs, the war in the south was practically ended in what was virtually a victory for the Americans. Congress presented Greene with a gold medal in honour of this battle, and the Carolinas and Georgia made him valuable grants of land. When peace was restored in 1783 he returned to Rhode Island, where he received numerous testimonials of the public admiration. In 1785 he retired with his family to his estate at Mulberry Grove, Georgia, where he died of sunstroke, 19th June 1786. Greene was one of the very best generals of the war of independence, second, perhaps, only to Washington, whose close friend he was. See the Life by his grandson, Professor G. W. Greene (3 vols. 1867–71), and that by Capt. F. V. Greene (1893).

Greene, ROBERT, an English poet and dramatist, was born at Norwich about 1560. He was placed at St John's College, Cambridge, and took his degree of A.B. there in 1578. He afterwards travelled in Spain and Italy. On his return he re-entered the university, and took his degree of A.M. at Clare Hall in 1583. He was incorporated at Oxford in 1588. On leaving Cambridge he proceeded to London, where he supported himself by writing plays and romances. He led a very irregular life, but his literary activity was ceaseless. 'Glad was that printer,' says Nashe, 'that might be so blest to pay him deare for the very dregs of his wit.' His romances, many of which are written in Lyly's manner, are frequently tedious and insipid; but they abound in beautiful poetry. One of them, *Pandosto, The Triumph of Time*, supplied Shakespeare with hints for the plot of *The Winter's Tale*. The most popular of his plays was *Friar Bacon and Friar Bungay*, which has an interesting story, and (in spite of occasional lapses into bombast) is attractively written. As Greene helped to lay the foundations of the English drama, even his worst plays are valuable in the eyes of students; but his literary fame rests on the poetry which he scattered through his romances—some of his pastoral songs being unsurpassed for tenderness and natural grace. Though his life may have been dissolute, his works are singularly free from grossness. He died of the consequences of a debauch, 3d September 1592, and was buried next day in the New Churchyard, near Bedlam. On his death-bed he sent a most pathetic letter to his wife, whom he had deserted. After his death appeared the singular pamphlet entitled *The Repentance of Robert Greene, Master of Arts*, in which he lays bare the wickedness of his former life. His *Groat's Worth of Wit bought with a Million of Repentance* contains one of the few authentic contemporary allusions to Shakespeare. Chettle, in *Kind-Harts Dreame*, describes him as 'of face amible, of body well-proportioned, his attire after the habite of a scholler-like gentleman, onely his haire was somewhat long.' Greene's plays and poems were edited by Alexander Dyce; his complete works (15 vols.), with a biography from the Russian of Storojenko, are included in the Huth Library of Dr Grosart, who also edited a selection, *Green Pastures* (1894).

Green Earth, a mineral of a green colour and earthy character, often found filling or lining the vesicular cavities of crystalline igneous rocks, sometimes also disseminated through highly decomposed basic eruptive rocks, in which it is evidently a product of the alteration of such minerals as pyroxene, amphibole, biotite, &c. It consists principally of silica, alumina, magnesia, and protoxide of iron, the silica constituting about one-half. There are probably several minerals included under the 'green earth' of such igneous rocks. Some of these closely resemble Serpentine (q.v.) and others Chlorite (q.v.), in their general appearance.—*Glauconite* is the name given to the green earth which is not infrequently met with in sedimentary rocks, such as some of the sandstones

in the Cretaceous system. In such rocks glauconite occurs in the form of grains, which in many cases are casts of minute shells. The same material has been met with in the shells of recent rhizopods and in fragments of coral dredged up in deep water. There is also a green earth used as a pigment by painters in water-colours, who know it by the name of *Mountain Green*. For their use it is mostly brought from Monte Boldo, near Verona, and from Cyprus.

Greenfinch, or GREEN LINNET (*Ligurinus chloris*), a bird of the finch family (Fringillidæ), a common resident in most parts of Britain, frequenting gardens and copses and cultivated districts generally. It occurs in many parts of Europe, and extends its range into Asia, also visiting in winter such regions as North Africa, Asia Minor, and Palestine. The bill is much thicker than that of the true linnets, to which, however, it is nearly allied. A prevailing green tint, mingling with gray and brown, characterises the plumage, and gives the bird its name. The female is much less brilliant and somewhat smaller than the male, which measures about 6 inches in length. The nest, usually placed in shrubs, is somewhat loosely built of fibres, moss, hair, and the like; the eggs (four to six) are greenish-white, with brownish or gray spots; two broods are often reared in a season. The food consists of insects, seeds, and berries. The proper song of the greenfinch is not very sweet, but in confinement it readily imitates the song of other birds, and in consequence of this and of its very easy domestication it is rather a favourite cage-bird. See Howard Saunders, *Manual of British Birds*.

Greengage, a variety of plum, of a green or yellow colour and roundish shape, the *Reine Claude* of the French, generally esteemed as one of the finest varieties in cultivation, if not certainly superior to all others. It is not of the largest size, but in delicacy and richness of flavour it is unsurpassed. Some reckon it a variety of *Prunus insititia*, others as a distinct species, *P. italica*.

Greenheart, or BEBEERU (*Nectandra Rodiæi*), a tree of the order Lauraceæ, a native of Guiana, of great value as a timber-tree, and also yielding a valuable medicinal bark. The timber is commonly called *Greenheart;* the bark is better known as *Bebeeru* (*Bibiri*, &c., or *Sipiri*), and its alkaloid as *Bibirine* or *Bebeerine* (q.v.). The wood is extremely strong and hard, resembling lignum-vitæ. It takes a high polish. It is so heavy as to sink in water. It is remarkable for its durability, and for being almost exempt from the attacks of the white ants on land and of the teredo in water. It is much valued by harbour engineers, and is admirably adapted for all purposes which demand exceptional strength and durability. Its costliness, however, largely restricts its use, save for turning. Other species yield valuable timber, notably *N. concinna*, the 'Laurier marbré' of Martinique. The seeds of *N. Puchury* are used as a digestive tonic, and in diarrhœa and dysentery, especially in Brazil; they are known as Pichurim Beans (*Faba pichurim* of pharmacy).

Greenhouse. See PLANT HOUSE.

Greenland, an extensive region, stretching, so far as we know, from 59° 45′ to 83½ N. lat. and from 17 to 73° W. long., its north-eastern extremity, however, being not yet accurately defined. It may be taken for proved that it constitutes an island engirt by smaller islands, but an island of almost continental size. Even its southern end has a thoroughly arctic character. It was discovered by the earliest Scandinavian settlers in Iceland. After having been sighted by Gunbjörn, it was visited by Erik the Red, who, after having explored it, founded there in the year 986 two colonies, the Osterbygd and Westerbygd (Eastern and Western Settlements). The colonies afterwards came under the dominion of Norway, but were neglected and suffered from disaster and privation. Finally, the Westerbygd was attacked and destroyed by Eskimo intruders from the north some years after 1340. Subsequently the connection with Europe gradually grew less and less, until, according to obscure accounts, it wholly ceased after 1448, and Greenland almost passed into oblivion. When it was rediscovered by John Davis in 1585 the Eskimo were the only inhabitants. In 1721 the modern Danish settlements on the west coast were founded by Egede (q.v.) as missionary stations. During the three centuries since Davis's discoveries the question of the site of the ancient colonies, and the possibility of remnants of a Scandinavian population being found somewhere, have been the subject of much discussion; they have even given rise to several expeditions. Remarkable ruins of undoubted Scandinavian origin were early discovered on two points of the west coast, one in the present district of Julianshaab between 60° and 61° N. lat., the other in Godthaab between 64° and 65°. In each case the ruins lie scattered over an area of some hundred square miles, occupying small flat and fertile spots around the heads of the fjords. The southern group contains about one hundred such spots, each with ruins of from two or three up to thirty houses (possibly the old Osterbygd); the northern group is smaller. In 1885 it was proved conclusively that no ruins of a similar description exist on the east coast. The part of the Greenland coast still unknown is that between Cape Bismarck in 76½° N. lat. and Independence Bay in 81° 37′, discovered in 1891 by Peary, about half a degree south of the NE. corner of Greenland, which he was the first to reach, and which he visited again in 1895. In 1898 he planned an expedition to the North Pole to start from this corner of Greenland.

The whole coast-line of Greenland may be roughly estimated at 3600 miles, or 192,000, following every island, fjord, and peninsula. The area again may be variously estimated at 512,000 and 320,000 sq. m., according as one includes or omits the islands and fjords running inland, which are 60 miles long on an average. The interior of Greenland is of great interest with regard to physical geography in general. Owing to its size and continental character, it is the only known home on the northern hemisphere of real icebergs. Nearly half of the supposed circumference of the interior has recently been explored by a series of expeditions, whose results explain adequately how the icebergs are produced. It has been proved that a huge ice-sheet covers the whole of the interior like a deluge. The surface of this enormous glacier, only occasionally interrupted by protruding mountain-tops, rises slightly towards the interior. Several travellers have tried to penetrate into this unknown region, crossing the ice till they reached heights of 7000 feet; but it was not until 1888 that Greenland was crossed from east to west (by Nansen), when the 'divide' was found to attain some 10,000 feet above the sea. On account of this ice-cap Greenland has no rivers corresponding to its magnitude; instead of its being drained by rivers, the inland ice at certain points of the coast is thrust into the sea by forces which have their origin in extensive lateral glaciers in the interior. These points are represented by the so-called ice-fjords, of which six or eight of first-rate magnitude are found in Danish Greenland (between 67° N. lat. on the east coast and 75° on the west coast). Five of these have been narrowly explored, and it has been ascertained that the inland ice, which produces the bergs, and whose thickness may be

estimated at 1000 feet, is pushed on an average with a velocity of 50 feet in twenty four hours into the sea, where it breaks into fragments—the bergs. The mass thus annually delivered into one of the largest class of ice-fjords would be equal in size to a mountain more than 1000 feet high and covering 4 sq. m.

The coast margin that surrounds the ice-covered inland is by no means devoid of perpetual ice itself, but its glaciers are more or less isolated. It is very mountainous; bold headlands, 3000 to 5000 feet high, are common in the north as well as in the south, and some mountains even rise to a height of 6000 to 7000 feet. Low flat land is found only in small patches, especially round the heads of some of the fjords. These inlets generally take the form of narrow channels, frequently more than 1000 feet deep. During the summer the whole east coast, and the west coast up to 64° N. lat., are more or less encumbered with drift-ice from the Spitzbergen sea.

The climate of Greenland, when contrasted with the climate of the eastern coasts of the Atlantic in the same latitude, shows a surprising difference. The southern point of Greenland has a mean temperature like that of the most northern shores of Iceland and Norway. But the difference consists more in the want of summer than in the severity of the winter. The following figures give the approximate mean temperature in Fahrenheit respectively of the summer, the winter, and the year for three stations on the west coast: Lichtenau (60½° N. lat.), 44°, 22°, and 33°; Upernivik (73° N. lat.), 38·2°, – 6·6°, and 13·3°; Renselaer Harbour (78½° N. lat.), 33·4°, – 28·6°, and – 2·5°. The minimum observed in the north was – 66·5°; the maximum in the south 68°. On the east coast, in 74½° N. lat., the summer heat was about 40°, the winter – 10°; the maximum was 55·6°, the minimum – 40·4°. The mean temperature of the winter months on the west coast is very variable from one year to another, owing especially to a warm wind from south-east and east.

The mountains of Greenland consist chiefly of granitic and gneissose rocks. On the west coast, between 69° 15′ and 71° 20′ N. lat., they are interrupted by high tablelands, consisting of trap and basalt, accompanied by sandstone and slate, with beds of coal. The fossil flora discovered in connection with the latter exhibits 613 species, partly Cretaceous, with subtropical forms, partly Tertiary, indicating a climate like that of southern Europe. Metallic ores have hitherto proved rather scarce. Besides coal, different varieties of graphite have been discovered, but the only mineral of real economical value hitherto made use of is cryolite, which is exported for the manufacture of soda and a very pure alum. The mine is situated at Ivigtut (61° 10′ N. lat.). It is worked by foreign labourers, and the export is about 10,000 tons annually. A remarkable collection of different minerals occurs in close connection with the cryolite, comprising lead and tin ore, but only in small quantities. Another peculiar group of minerals occur in connection with eudialyte somewhat farther south; this mineral also has become an object of commercial speculation. A mineralogical rarity is finally the native iron, of which a mass found on Disco Island was estimated to weigh 46,200 pounds.

In sheltered slopes and valleys around the fjords south of 65° N. lat. copse-woods are found, consisting of alder, white birch, more rarely rowan-trees, which grow to 6 or 8 feet high. The highest birch discovered measured about 14 feet. Berries are abundant, especially crowberries and whortleberries. An attempt to grow potatoes at the southmost settlement failed. The Greenland flora comprises 395 species of phanerogams and higher cryptogams, and 330 species of mosses.

The fauna numbers 33 species of mammalia, 124 of birds, 79 of fishes. It is from the animal kingdom, especially from the seals and whales, that the natives derive almost their whole subsistence. The number of these animals annually killed in the Danish trading districts on the west coast is estimated as follows: *Phoca fœtida*, 51,000; *Phoca vitulina*, 1000; *Phoca grœnlandica*, 33,000; *Phoca barbata*, 1000; bladdernose seals, 3000; walrus, 200; white whales, 600; narwhals, 100; humpback whales, 1 or 2. Reindeer, of which 25,000 were shot annually in the years 1845–49, are now rather scarce. Of fish sharks only have any commercial value, but several other kinds afford food for the inhabitants. American ships have for some years tried halibut-fishery on the banks off the west coast. The dogs used for draught are of great importance in the north. A few goats and horned cattle have been kept by the Europeans, but more as a curiosity.

The inhabitants of Greenland (see ESKIMO) are of the Eskimo race, more or less mixed with European blood. The individuals of the mixed race hardly differ as to language and habits from the genuine Eskimo. Besides the natives, about 250 Europeans usually reside in the country, thirty to forty of whom have married native women. The number of natives, including the mixed race, was, in Danish West Greenland, 9648 in the year 1855, 9983 in 1886; in Danish East Greenland, 548 in 1884; the Smith Sound tribe may number 150; and lastly some few must be added for the imperfectly known north-eastern coast, where natives have been met with. The whole population in this way may amount to 11,000.

Since 1774 the trade of Greenland has been a royal monopoly; the service employs 2 inspectors, 30 agents and clerks, and 180 handicraftsmen, boatswains, and labourers, most of the latter being natives. There are 12 chief stations for trading and the Danish Mission; the southernmost is Julianehaab (60° 42′ N. lat.), the northernmost Upernivik (72° 48′ N. lat.). At Godthaab there is a seminary for training native catechists; of late, too, natives have been appointed pastors. The Moravian Mission has four chief stations. Since 1863 a municipal system has been tried, for which native representatives are elected by their countrymen. During the twenty years from 1853 to 1872 the annual export by the royal trade was 1185 tuns of oil and 40,000 skins, besides some eider-down, feathers, &c. In 1890–95 the exports and imports were each a value of between £25,000 and £30,000 a year.

Further information will be found in *Danish Greenland*, by the present writer (Lond. 1877), and the series *Meddelelser om Grønland* (Copenhagen, 1879–95), which give the results of investigations since 1876. As regards the rest of Greenland, our principal sources are, for the east, the works of Scoresby, Clavering, and the second German north polar expedition; information about the north-western part is scattered over the reports of several well-known Arctic expeditions, especially those by Kane, Hall, Nares, and Greely. See also Nordenskiöld's record of his exploration on the east coast and the interior (German, 1886), and Nansen's account of his expedition across the interior of southern Greenland in 1888.

Greenlaw, a small town of Berwickshire (q.v.), on the Blackadder, 38 miles ESE. of Edinburgh (by rail 55). Its court-house (1834) is a large Grecian pile. Pop. 744.

Greenlet Island, a small island in the Strait of Belle Isle, in 51° 34′ N. lat. and 56° 36′ W. long., the proposed landing-place of a Canadian Atlantic cable, to extend from near Clew Bay, in Ireland.

Green Mountains, a portion of the Appalachian Range. See APPALACHIANS.

Greenock, an important seaport of Renfrewshire, the seventh largest town in Scotland, on the southern shore of the Firth of Clyde, 3¾ miles by water S. of Helensburgh, and 22½ by rail WNW. of Glasgow. For more than four miles it stretches along the level strip of ancient sea-margin, or climbs up the slopes of the hills, which rise rapidly behind it to a height of 813 feet, and which command splendid views of the opposite coasts of Argyll and Dumbarton shires, fringed with white gleaming villages, of Highland mountains, and of the firth itself, stretching away into narrow sea-lochs, and dotted with every variety of craft. Greenock has a reputation of being always wet, and the yearly rainfall does exceed 60 inches; but as the prevalent winds are from the south and west, they are generally mild. The west end of the town, with its elegant and commodious villas of every style of architecture, its beautiful esplanade 1½ mile long, its wide and well-paved streets, planted with trees, is particularly attractive. The public buildings are many of them very handsome. The chief among these is the town-hall and municipal buildings (1886), Renaissance in style, with a tower 245 feet high; then come the county buildings (1867), the custom-house (1818), the poorhouse and lunatic asylum (1876), Wood's Mariners' Asylum (1851), the temperance institute (1870), the Y.M.C.A. Institute (1887), and the Watt Institution (1837), containing a marble statue of Watt by Chantrey. There are several handsome churches. To Sir Michael Shaw-Stewart the town is largely indebted for the Well Park (1851), the Wellington Park (1872), and the Lyle Road (1880). The new cemetery, 90 acres in extent, with its Watt cairn, and the magnificent water-works (1827–83) also deserve mention. The harbour-works date from 1707, and have cost upwards of 1½ million pounds. Accessible at all states of the tide, they include Victoria Harbour (1850), the Albert Harbour (1866), and the James Watt Dock (1886). The tonnage of vessels belonging to Greenock rose from 29,054 in 1825 to 103,919 in 1867, and 229,912 in 1888 (besides 306 fishing-boats); whilst the tonnage of vessels entering the port ranges between 1 and 1½ million per annum. Shipbuilding has been carried on since 1760; and during the twelve years 1876–87, the tonnage of vessels built here (mostly iron or steel steamers) varied from 14,500 in 1877 to 52,744 in 1882. Sugar-refining, commenced in 1765, in spite of bad recent years has still its chief seat at Greenock; and there are also manufactures of steam-engines, anchors and chain-cables, ropes, sailcloth, paper, wool and worsted, &c. Since 1832 Greenock has returned a member to parliament. Pop. (1696), 1328; (1801) 17,190; (1851) 36,689; (1881) 66,704; (1891) 63,423. Created a burgh of barony in 1635, Greenock owes its growth from a mere fishing-village to the Shaw family and to the Treaty of Union (1707), by which free commerce was opened up with America and the West Indies. Besides being the birthplace of Watt, of Spence the mathematician, and of Principal Caird, it has memories of Rob Roy, John Wilson, and Galt, and contains the grave of Burns's 'Highland Mary.' See Provost Dugald Campbell's *Historical Sketches of the Town and Harbours of Greenock* (2 vols. 1879–81).

Greenough, HORATIO, an American sculptor, was born in Boston, 6th September 1805, studied for two years at Harvard, and from 1825 spent the greater part of his life in Italy. His principal work, and one remarkable both for accuracy and for lofty conception, is the colossal statue of Washington, which now stands in front of the national capitol building. Other important sculptures are his 'Medora,' 'Venus Victrix,' and a group of four figures, 'The Rescue,' for the purpose of placing which he returned to America in 1851. He died suddenly at Somerville, Massachusetts, 18th December 1852.

Green Pigments. These are numerous and some are very important. Several of them are mechanical mixtures of blue and yellow; a larger number are chemical compounds which are naturally green; but of either kind only a few are extensively used. All those which are serviceable or have any special interest are noticed in what follows.

Sap green is the only one of vegetable origin that need be mentioned. It is prepared from the gummy juice of the berries of a species of buckthorn (*Rhamnus catharticus*), and is a fine transparent yellowish-green. It is unfortunately fugitive, but is occasionally employed in water-colour painting.

Terra verte is a kind of ochre. This pigment is much used by artists for painting in oil, being one of the most permanent greens. It has not much body, but can be mixed with other colours without injurious results.

Oxide of chromium, like the last, is found native, but for use as a colour it is always artificially prepared. It is a sober, permanent green much liked by some landscape-painters. *Viridian* and *Veronese green* are also oxides of chromium, but the latter is often adulterated with arsenic.

Emerald green (cupric aceto-arsenite).—This very bright (but poisonous) green, also called *Schweinfurt green* and *Paris green*, is employed to a limited extent by artists and decorators, and is used as an insecticide.

Scheele's green (cupric arsenite) is another bright green, although not so vivid in colour as the last, which it resembles in stability and in other properties. This is a dangerous pigment, and is unfortunately a good deal employed for colouring paper-hangings, artificial leaves, and toys.

Brunswick Green.—Several distinct pigments are known by this name. One of the kinds employed by the house-painter is a basic carbonate of copper, mixed with gypsum or other bodies. It is fairly permanent. Mountain green, mineral green, and malachite green are also carbonates of copper. In chemical books Brunswick green is usually said to be the oxychloride of copper. Chrome green, noticed below, is likewise called Brunswick green.

Rinman's green, known also as zinc green and cobalt green, consists of 88 per cent. of oxide of zinc and 12 per cent. of protoxide of cobalt. This colour is permanent, and is not affected by strong heat.

Chrome green is a mixture of chromate of lead and Prussian blue. It is a bright, strong colour, and is suitable for ordinary mechanical painting. It is, however, not permanent; a more durable green, but one of less power, being formed with French ultramarine and chrome yellow.

Hooker's green is a mixture of Prussian blue and gamboge, and possesses some permanence as a water-colour. *Prussian green* is formed in the same way, but contains more blue.

Greens which are compounds of copper are all more or less poisonous even when they do not also contain arsenic.

Artists generally prefer to make up the shade of green they require by mixing blue and yellow pigments for bright shades, and blue and brown colours for dull shades. As a rule the green portions of pictures have stood the effects of time worse than other colours.

For the materials used in dyeing textile fabrics green, see DYEING and CALICO-PRINTING; and for

green colours used in painting or printing pottery, see POTTERY.

Green River (1) rises in Western Wyoming, flows SE. into Colorado, and then SW. and S. through Utah, joining the Grand River, a branch of the Colorado, after a course of 750 miles. — (2) Green River, Kentucky, rises near the centre of the state, flows west and north-west, passing near the Mammoth Cave, and crosses the northern boundary, entering the Ohio 9 miles above Evansville, Indiana. It is about 350 miles in length, and is navigable for small steamers for 150 miles; its lower course is through the coalfields of Western Kentucky.

Greenroom, a room near the stage in a theatre, so called because originally painted green, where, during a performance, the actors wait while off the stage.

Greens, the common name of all those varieties of kale or cabbage (*Brassica oleracea*) which do not boll, and of which the leaves are used for the table as boiled vegetables; some of which are also called colewort, &c., whilst others, particularly those with curled leaves, as German greens, have no other name than greens or kale. Young unbolled cabbages, and shoots from the stocks of cabbages, are often also called greens, as well as turnip-tops, and other leaves of plants used in the same manner.— The leaves of German greens are very much waved or curled. This herb is one of the best kinds of *open* greens. It is either sown in spring and planted out soon after, or it is sown in autumn and planted out in spring.

Greensand, the name given to two divisions of the Cretaceous System (q.v.). They are so called from the occurrence in some of the strata of numerous small green specks of glauconite (a hydrous silicate of iron, alumina, and potash; see GREEN EARTH), sometimes so abundant as to give a green colour to them. The term is, however, far from being descriptive of the various included strata; it must be considered simply as a name. In some districts, especially on the Continent, the green particles are entirely absent from the strata. The petrographical character of the Upper Greensand is so like that of the Lower, that it is scarcely possible to separate them when the intermediate Gault is absent, except by their organic remains, which are very distinct; so much so, indeed, as to have caused the placing of the one series in the Lower Cretaceous group, and the other in the Upper.

The *Upper Greensand* consists of beds of sand and sandstone, generally of a green colour, with beds and concretionary masses of calcareous grit, called firestone, and chert. In the Wealden district the average thickness of the formation is about 60 feet. It is only doubtfully present north of Folkestone: in Sussex it reaches 20 feet, and in the Isle of Wight 100 feet in thickness. This formation is supposed to have been a littoral or shore deposit of the cretaceous sea. While the chalk was being deposited out at sea these sands were being laid down along the shore contemporaneously with the chalk, although they appear inferior to it. Their position would necessarily result from the cretaceous sea widening its area; as the shore was submerged the greensand became covered with the chalk, and thus appears as an older and underlying deposit. The beds of this series are rich in fossils, abounding especially in the remains of sponges, mollusca, and echinodermata.

The *Lower Greensand* consists chiefly of yellow, gray, white, and green sands, but includes also beds and bands of clay, limestone, and ironstone. It attains a thickness of 500 or so feet. The sands preponderate in the upper, and the clays in the lower portion of the formation. In Surrey, Kent, Sussex, &c. it is subdivided as follows:

4. Upper Greensand beds.
3. Sandgate beds.
2. Hythe beds.
1. Atherfield clay.

Some beds of clay of considerable thickness, occasionally as much as 60 feet, are used as fuller's earth. The calcareous stone is a highly fossiliferous band of limestone, locally called Kentish rag, much used for building in Kent and Sussex. The formation was formerly known as the iron-sand, because of the sands being cemented together by an abundance of oxide of iron; this gives them a reddish colour. The Lower Greensand contains numerous fossil mollusca and other remains. It is a marine-deposit, and rests on the fresh-water Wealden strata, showing that while it was being accumulated the sea made considerable encroachments on the land. In the Isle of Wight the strata are well developed, reaching a thickness of some 800 feet. In the Midland counties the same beds are recognised and have assumed various names, such as 'Faringdon beds,' 'Shotover sands,' 'Woburn sands and Wicken beds.' The Tealby series is the name given to the Lower Greensand beds of Lincolnshire. Near Flamborough Head the Lower Greensand and Wealden beds are represented by the Speeton clay.

Greenshank (*Totanus canescens*), a bird of the snipe family (Scolopacidæ), in the same genus as the redshank and some of the sandpipers. It is about the size of a woodcock (14 inches in length),

Greenshank (*Totanus canescens*).

but has much longer legs; the general colours of the plumage are brown and gray, the latter prevailing in winter, when the under surface is pure white; the bill is about 2 inches long; the tail is short. The greenshank nests on the ground, which the eggs (four) more or less resemble in colour; when disturbed the bird behaves and cries very much like a lapwing. The food consists of small animals of all sorts. In spring and autumn small flocks occur on the British coasts or by inland lakes; in Ireland it often winters, and in the north of Scotland may even breed. Its general range is virtually co-extensive with the eastern hemisphere. See Howard Saunders, *Manual of British Birds.*

Green Sickness. See CHLOROSIS.

Greenstone, a rock term (now disused) for any dark green basic crystalline 'trap-rock.' The greenish tint which such igneous rocks so frequently show is now recognised as being in most cases due to the presence of serpentine, chlorite, or other products of decomposition. Most greenstones are thus

referable to the Basalts (q.v.) and the Diorites (see IGNEOUS ROCKS).

Greenville, capital of Greenville county, South Carolina, on Reedy River, 95 miles (143 by rail) NW. of Columbia, with a cotton-factory, and manufactures of oil, flour, furniture, and machinery. It is the seat of a Baptist university (1851) and of a Baptist ladies' college. Pop. (1890) 8607.

Greenweed, a name given to certain half-shrubby species of *Genista*. See GENISTA, and Dyer's Broom (*G. tinctoria*) under BROOM. Hairy Greenweed (*G. pilosa*) is sometimes grown in France on light soils as fodder for sheep.

Greenwell, DORA, religious poet, was born 6th December 1821 near Lanchester in Durham, and after 1848 lived in Durham. She died 29th March 1882. Amongst her works, all marked by a lofty strain of patience, Christian hope, holy confidence, and withal of deep-seated melancholy, are a volume of poems in 1848, and another in 1861; several short prose works, including *The Patience of Hope*, *Two Friends*, and a sequel, *Colloquia Crucis;* a Life of Lacordaire (1868), and *Carmina Crucis* (1869). See the *Memoirs* by William Dorling (1885).

Greenwich (A.S. *Green-wic*, 'green creek or bay'), a parliamentary borough of Kent, is situated 5 miles ESE. of London Bridge, on the south bank of the Thames, here crossed by a steamship ferry, on the American system, which was opened in 1888. The town is chiefly memorable on account of its great national institutions. First amongst these comes Greenwich Hospital, which occupies the site of an old royal palace, in which Henry VIII. and his daughters Mary and Elizabeth were born, and where Edward VI. died. The first idea of its foundation is said to have originated in 1692 after the great naval victory of La Hogue; it was then proposed to raise a suitable monument as a mark of the gratitude which England felt towards her brave sailors. According to the Latin inscription which runs round the frieze of the hall, 'The pious regard of Queen Mary dedicated this Palace of Greenwich for the relief and maintenance, at the public expense, of those seamen who have protected the public safety in the reign of William and Mary, 1694.' The hospital consists of four distinct piles of buildings, all of which are quadrangular and named according to the respective sovereigns in whose reigns they were successively built. King Charles's building, to the west, was erected in 1664, from the original design by Inigo Jones. On the other side of the square towards the east is Queen Anne's building; to the southward of these are King William's building, containing the Great Hall, and Queen Mary's building, containing the chapel. The last three were from designs by Sir Christopher Wren. The Great Hall is remarkable for its painted ceiling, a work carried out by Sir James Thornhill in 1707–27. It contains several valuable pictures of great naval battles and of the heroes who fought in them; there is still preserved the coat which Nelson wore when he was shot at Trafalgar. The chapel is a fine specimen of Greek architecture; it was restored in 1789 from designs by James Stuart. A statue of George II. by Rysbrach adorns the central square.

The first pensioners were received in the hospital in 1705; these numbered 100; in 1814 the maximum number was reached—viz. 2710. In 1763 outpensions were granted from the funds; in 1849 the number of in-pensioners began to decrease, until in 1865 they only numbered 1400. For some time the in-pensioners had been discontented with their manner of living at the hospital, and in 1869, when they had the option of receiving a grant of money in lieu of their board and lodging, a very large majority preferred to take the money and go to their friends. A few old or bedridden men were transferred to the various naval hospitals and the Seamen's Hospital Society, to be maintained at the expense of Greenwich Hospital Fund. Greenwich Hospital was thus disestablished by the votes of the very men for whose benefit it was originally founded. The revenues of the hospital are derived from different sources, the principal of which are gifts by King William and the original commissioners, the rental of the forfeited estates of the Earl of Derwentwater, contributions of the seamen and marines of Her Majesty's fleet, as well as from those who served in the mercantile marine; large sums have been acquired from unclaimed prize-money and fines. The annual income of the hospital is £167,259. From this sum numerous pensions are paid; 1000 boys, the sons of seamen and marines, are maintained and educated at Greenwich Hospital Schools at an average cost of £23,000 a year; gratuities are granted to widows of seamen and marines; and 50 children of officers who have died receive grants for their education. It is estimated that 9000 persons, exclusive of the children mentioned, derive benefit from the funds. In 1873 Greenwich Hospital became the college for the Royal Navy, and all naval officers belonging to the combatant branch are now compelled to take their degree at Greenwich. Having reached a certain seniority as midshipmen, they are entered at the college, and, after having passed through a course of instruction, they are examined and classified according to merit. Executive officers of different ranks have the privilege of studying and earning extra distinctions by passing meritorious examinations. A certain number of the engineer officers also go through a course of study at the Royal Naval College.

The Naval Museum contains many objects of interest connected with the navy, such as models of ships both ancient and modern, specimens of guns, torpedoes, and ammunition, plans of British dockyards, relics of Sir John Franklin's expedition, and, last but not least, the famous original Chatham chest—established at Chatham by Queen Elizabeth in 1588 for the relief of wounded and decayed seamen, and removed hither in 1803.

The Royal Hospital School was first established in 1712 for the purpose of clothing and educating the sons of the pensioners. One thousand boys enjoy its benefits, besides one hundred day-scholars nominated under the Boreman Trust. Entries are made at 11 years of age, and, if the boys prove fit for service in the navy, they are retained till they reach the age of 15½ years. The school is essentially a training place for the Royal Navy, the boys being passed thence to training-ships at Portsmouth and Devonport. The 'Queen's House' in the centre of the school buildings was a favourite residence of Queen Henrietta Maria. The school possesses a spacious gymnasium, a large swimming-bath, several good model rooms for seamanship instruction, and a very fine dining-hall. The admissions are limited to the sons of seamen of the Royal Navy, the Royal Marines, and the Royal Naval Reserve, with a few from the mercantile marine.

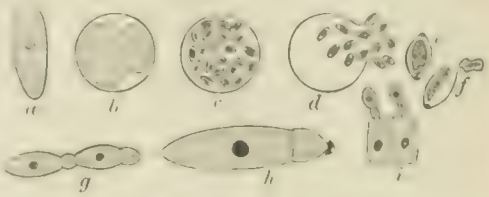
Another national institution at Greenwich, not less important than these naval establishments, is the Royal Observatory, which crowns the hill that rises in the park behind the hospital (see OBSERVATORY). It was built by Charles II. in 1675, the first astronomer-royal being Flamsteed. From here the correct time is flashed every day by the electric telegraph to the principal towns of the kingdom. From Greenwich, too, geographers and seamen reckon longitude. The park is a favourite

resort of Londoners on Sundays and holidays. The Whitebait (q.v.) Dinner, a banquet held by the cabinet ministers to celebrate the termination of a parliamentary session, is held at Greenwich, which is famous for the fish from which the dinner is named. Greenwich is well supplied with charitable institutions, chief among which may be mentioned the Jubilee Almshouses, Norfolk or Trinity College, Roan's Charity, the Green-coat and Blue-coat Schools. The manufacturing establishments of the town include engineering, telegraph works, chemical works, &c. It returned two members to parliament down to 1885, when the new parliamentary boroughs of Deptford and Woolwich were formed out of its boundaries, and it was restricted to one member. Pop. (1881) 65,411; (1891) 78,131. See the Rev. A. G. L'Estrange, *The Palace and the Hospital: Chronicles of Greenwich* (2 vols. 1886).

Greg, William Rathbone, author of several works in literature and politics, was born in Manchester in 1809, became a Commissioner of Customs in 1856, and acted as Controller of Her Majesty's Stationery Office from 1864 to 1877, when he resigned. He died November 15, 1881. He was a man of profoundly earnest character, had a conspicuous power of incisive writing, and was interested in many philanthropic measures. In his *Rocks Ahead* he took a highly pessimistic view of the future of England, and regarded some present tendencies as pregnant with danger, anticipating with foreboding the political supremacy of the lower classes, the approaching industrial decline of England, and the divorce of the intelligence of the country from its religion. His works include *The Creed of Christendom* (1851); *Essays on Political and Social Science* (1854); *Literary and Social Judgments* (1869); *Political Problems* (1870); *Enigmas of Life* (1872; 18th ed. with memoir by his widow, 1891); *Rocks Ahead, or the Warnings of Cassandra* (1874); *Mistaken Aims* (1876); *Miscellaneous Essays* (2d series, 1884).

Gregarinida, or Sporozoa, a class of parasitic single-celled animals or Protozoa. As adults they are entirely destitute of cilia or other locomotor structures, and emphasise in their history the encysted phase of cell-life. They are found in almost all kinds of animals, inside the cells, or loose in the alimentary canal, body-cavity, and other spaces. The food consists of the diffusible albuminoids of the host, absorbed by the general surface of the 'mouthless' unit. The Gregarine is wholly surrounded by a rind, and sometimes shows fibril-like, probably contractile, structures; there is a large spherical nucleus, but no contractile vesicle. They vary greatly in size, from minute forms which live within blood corpuscles to others visible to the unaided eye, and measuring sometimes $\frac{1}{12}$th of an inch. A typical life-history is indicated in the diagram, the important points being as follows: in early life the Gregarine usually lives inside a cell, whether it keep this habitat or not; the young forms not unfrequently divide; Gregarines are fond of associating in couples (or even in trios), but this union does not seem to be usually followed by fusion; at a certain stage the unit, or sometimes the pair, becomes encysted and divides into numerous clothed spores; each of these, when liberated by the bursting of the cyst, gives origin to a young Gregarine, or usually to several; these are at first flagellate or amœboid, or at least more active than the adults, but with nutrition and growth the juvenile activity is soon lost.

Among the most important Sporozoa are the following: Monocystis, represented by at least two species in the male organs of the earthworm; Gregarina, a type of those with the body divided by a partition, and furnished with a curious, anterior, proboscis-like appendage, found in the alimentary canal of crustaceans and insects—e.g. lobster and cockroach; Klossia, in molluscs, especially cuttle-fish; Drepanidium, in frog's blood, a



Life-history of Gregarine:

type of many with a similar habitat in birds and reptiles. Very imperfectly known are the Myxosporidia found in fishes—apparently very primitive forms—and the Sarcosporidia in the muscle-fibres of mammals, of which Sarcocystis ('Miescher's vesicles' or 'Rainey's corpuscles') is common, but apparently harmless in butcher-meat. *Coccidium oviforme* is definitely known as a Gregarine parasitic in man.

Grégoire, Henri, the most remarkable among the so-called constitutional bishops of France, was born of poor parents at Vého, near Lunéville, December 4, 1750. Educated by Jesuits at Nancy, he took orders, and lectured for some time at the Jesuit College of Pont-à-Mousson. His *Essai sur la Régénération des Juifs* (1788) breathed the toleration that was in the air, and became widely popular. Becoming curé of Emberménil, he was sent to the States-general of 1789 as one of the deputies of the clergy. He was an ardent democrat in all his views, and, attaching himself from the first to the Tiers-état party, acted a prominent part throughout the grand drama of the Revolution. One of the secretaries of the National Assembly, he supported enthusiastically the abolition of the privileges of the nobles and clergy alike, and the civil constitution of the clergy. He was the first of his order to take the oaths, and was elected the first 'constitutional bishop' of the department of Loir-et-Cher, which he accepted, although the old and legitimate bishop, Monseigneur de Thémines, was still alive. Grégoire carried into every department the stern democracy to which he was devoted, and which he identified with the Christian brotherhood of the gospel; and upon the fundamental doctrine of the Revolution—the rights of man—he sought to ingraft his own early advocacy of the Jews and of the negroes, and especially the doctrine of the duties of man. At the blasphemous Feast of Reason, the weak Gobel, constitutional Bishop of Paris, publicly renounced Christianity; but Grégoire faced the infuriated rabble with all the courage of the primitive martyrs, and refused to deny his Master. After the 18th Brumaire he became a member of the Corps Legislatif. His

extreme republicanism was highly distasteful to Bonaparte, and it was only after a third attempt that he was appointed member of the senate. On the conclusion of the concordat between Pius VII. and Bonaparte he ceased to exercise ecclesiastical functions, being unable conscientiously to give the retractations required by the church, and he died without reconciliation at Auteuil, near Paris, 28th May 1831. His *Mémoires* were edited by H. Carnot, with a life (1831). Of his numerous writings may be named *Histoire des Sectes Religieuses* (1814); *Essai historique sur les Libertés de l'Église Gallicane* (1818). See the studies by Krüger (Leip. 1838) and Böhringer (Basel, 1878).

Gregorovius, FERDINAND, a distinguished German historian, born in East Prussia, 19th January 1821. He studied theology at Königsberg, but soon devoted himself to poetry and literature. In 1852 he settled in Rome, where he died 1st May 1891. His great work is the *History of the City of Rome in the Middle Ages* (8 vols. 1859–72; translated from the 4th German edition, vols. i. and ii. 1895). He wrote also on Italian geography and history, on Corsica (1854), Capri, and Corfu, on the graves of the Popes (1857; 2d ed. 1881), on Lucrezia Borgia (1874), on Urban VIII. (1879), on Athens (1889), and on the Byzantine empress, Athenais (3d ed. 1891); also a tragedy on the death of Tiberius (1851), and an epic, *Euphorion* (6th ed. 1891).

Gregory, the name of sixteen popes, of whom five were specially noteworthy.

GREGORY I., THE GREAT, a father and saint of the Roman Catholic Church, was born in the city of Rome about the middle of the 6th century. His father Gordianus was a senator of the same family as that to which Pope Felix III. had belonged, and his mother Sylvia was famed for her surpassing virtues. At a comparatively early age Gregory was appointed by the Emperor Justin II. to the important charge of prætor of Rome; but he voluntarily relinquished this office, and withdrew altogether from the world into a monastery at Rome, one of seven he had founded. 'He lavished on the poor all his costly robes, his silk, his gold, his jewels, his furniture, and not even assuming to himself the abbacy of his convent, but beginning with the lowest monastic duties, he devoted himself altogether to God.' This was probably about 575. It was while here that he saw one day some fair-haired Anglo-Saxon youths in the slave-market—'non *Angli* sed *angeli*'—and was seized with a longing to devote himself to the conversion of their country to Christ. He set forth on his journey, but the clamour of the Romans at his loss led the pope Benedict to compel his return, and eventually to enrol him in the secular ministry by ordaining him one of the seven Regionary Deacons of Rome. Benedict's successor, Pelagius II., sent Gregory as nuncio to Constantinople, to implore the emperor's aid against the Lombards. He resided three years in Constantinople, during which time he commenced, and perhaps completed, his *Moralia*, an exposition of Job. On his return to Rome he resumed his place as abbot of his monastery, and on the death of Pelagius, in a plague which laid waste the city, was unanimously called by the clergy, the senate, and the people to succeed him. He used every means to evade the dignity, even petitioning the Emperor Maurice to withhold his consent, but was forced to yield, and was consecrated September 3, 590.

Few pontiffs have equalled, hardly one has surpassed, Gregory I. as the administrator of the multiplied concerns of the vast charge thus assigned to him. 'Nothing,' says Dean Milman, 'seems too great, nothing too insignificant, for his earnest personal solicitude; from the most minute point in the ritual, or regulations about the papal farms in Sicily, he passes to the conversion of Britain, the extirpation of simony among the clergy of Gaul, negotiations with the armed conquerors of Italy, and the revolutions of the Eastern Empire.' There is no department of ecclesiastical administration in which he has not left marks of his energy and his greatness. To him the Roman Church is indebted for the complete and consistent organisation of her public services and the details of her ritual, for the regulation and systematisation of her sacred chants. The mission to England, which he was not permitted to undertake in person, was entrusted by him, with all the zeal of a personal obligation, to Augustine; and, under his auspices, Britain was brought within the pale of Christendom. Under him also the Gothic kingdom of Spain, long Arian, was reconciled with the church. Nor was his zeal for the reformation of the clergy, and the purifying of the morality of the church, inferior to his ardour for its diffusion. His letters, which are numerous and most interesting, are full of evidences of the universality of his vigilance. On the occasion of the threatened invasion of Rome by the Lombards he showed himself in act and in influence, if not as yet in avowed authority, a temporal sovereign. Against the memory of his administration of Rome a charge was formerly made, that in his zeal against paganism he destroyed the ancient temples and other buildings of the pagan city. But Gibbon confesses that the evidence is 'recent and uncertain;' and, indeed, the only authority to which Gibbon himself refers, Platina, simply mentions the charge in order to repudiate it. Though Gregory had a contempt for mere letters, and thought the oracles of God were above the rules of grammar, it is not true that he burned the Palatine Library in his hatred of pagan literature. As regards the general government of the church, Gregory reprobated very strongly the assumption by John, patriarch of Constantinople, of the title of Ecumenical or Universal Bishop, the more especially as the object of John in assuming this title was to justify an exercise of jurisdiction outside of the limits of his own patriarchate. In his writings, too, the details of the whole dogmatical system of the modern church are very fully developed. His *Letters*, and, still more, his *Dialogues* abound with miraculous and legendary narratives, which, however uncritical in their character, are most interesting as illustrating the manners and habits of thought of that age. With all his zeal for the diffusion of Christianity, Gregory was most gentle in his treatment of heathens and Jews, and he used all his efforts to repress slave-dealing and to mitigate the severity of slavery. He died March 12, 604. Besides his *Moralia* he left homilies on Ezekiel and on the Gospels, the *Regula* (or *Cura Pastoralis*), and the *Sacramentarium* and *Antiphonarium*. In exegesis he is a fearless allegorist. The best editions of his works are the Benedictine (4 vols. folio, 1705) and that in Migne's *Patrologia* (vols. lxxv.–lxxix.).

See the studies by Lau (1845) and Pfahler (1852); Rev. J. Barmby's little book in the 'Fathers for English Readers' (1879); Kellett, *Gregory the Great* (1889); the monograph by Abbot Snow, O.S.B. (1892); and Zöpffel's article in Herzog-Plitt's *Real-Encyklopädie*.

GREGORY II., by birth a Roman, was elected pope in 715. His pontificate is specially noticeable as forming an epoch in the progress of the territorial pre-eminence of the Roman see in Italy. The eastern emperors having almost entirely abandoned the government and, still more, the defence of Italy, and the aggressions

of the Lombards becoming every year more formidable, the imperial authority in the West sank into little more than a name; and the tyrannical and barbarous measures by which the Emperor Leo the Isaurian attempted to enforce his decrees against image worship weakened still more the tie which bound Italy to the eastern emperors. The natural result of the diminution of the imperial authority in Italy was the growth of that of the pope, to whom the deserted Italian provinces looked, partly as their spiritual counsellor and head, partly as their mediator with the barbarous enemy, partly as the centre of the political federation for self-defence which their very isolation necessitated. Gregory convened a council in Rome on the subject of the honour due to images, and addressed a very energetic letter to the emperor, protesting against the sacrilegious outrages of which he had been guilty, explaining and defending the Catholic doctrine on image-worship, and warning the emperor that the feelings of his subjects were so completely alienated by his conduct that it was only the pope's influence which prevented them from throwing off all allegiance. Gregory has been accused of himself fomenting this disaffection. The contrary, however, is attested, not only by his own letters, but also by Paul the Deacon, in his *History of the Lombards* (book vi. chap. 39); and it is quite certain that the circumstances themselves, and the well-known character of the emperor, would sufficiently explain any degree of discontent in Italy. At all events, the result of the contest was a most notable aggrandisement of the political authority and influence of the popes in Italy. Gregory II. was distinguished by his zeal for the evangelisation of heathen lands; it was under his auspices that the famous Winfried or Boniface entered on his missionary work in Germany. He died in 731.

GREGORY III., a native of Syria, succeeded Gregory II. in 731. In the same year he hurled the anathema of excommunication against the Iconoclasts, and the retaliations of Leo the Isaurian did much to weaken the ancient tie between the popedom and the empire. The encroachments of the Lombards in Italy during his pontificate became so formidable that, as the eastern emperors still remained powerless or indifferent to the protection of the Italian provinces, the Romans charged Gregory to send a deputation to Charles Martel, soliciting his succour against the enemy, and proposing upon that condition to recognise him as their protector, and to confer on him the title of consul and patrician of Rome. This offer was made by the pope 'in virtue of a decree of the Roman primus,' and is of great historical importance in the consideration of the nature and origin of the papal power in Italy. The embassy failed, owing to the pressure of his war with the Saracens, to enlist the aid of Charles; but it was a step towards the consummation of the independence of the West. Gregory III. died in 741.

GREGORY VII., pre-eminently the historical representative of the temporal claims of the medieval papacy, was born, about 1020, at Soana, a village in the southern border of Tuscany. Whether his family belonged to the burgher or the noble class is disputed by his biographers. His family name, Hildebrand, would imply a Teutonic descent; but by birth and education at least he was Italian. His youth was passed at Rome, in the monastery of St Maria, on the Aventine, of which his uncle, Laurentius (afterwards Bishop of Amalfi), was abbot. From Rome he passed into France, where he entered the celebrated monastery at Clugny, in the schools of which he completed his education; and from the strict ascetic observances there practised by him he acquired those habits of austerity which distinguished his whole life. He visited the court of Henry III., and obtained by his preaching the reputation of great eloquence. On his return to Rome he became the chaplain of Gregory VI.; but after the death of that pontiff he again withdrew to his former retreat at Clugny, from which he was only recalled by the earnest appeal of the new and zealous pope, Leo IX., whom he accompanied to Rome in 1049. Under this active and devoted pontiff Hildebrand exercised great influence. He now for the first time received holy orders, and was eventually created cardinal. Besides the responsible domestic employments which were assigned to him, he was sent as legate to the important Council of Tours, in which the cause of Berengarius was examined. Under all the short but important pontificates of the successors of Leo IX., who are known in history as the German popes—Victor II., Stephen IX., Benedict X., and Alexander II.—Hildebrand continued to exercise the same influence, and by inspiring into their government of the church the great principles to which his life was devoted he prepared the way for the full development of his theory of the papacy.

He was unanimously elected at Rome, without awaiting the imperial authorisation, three days after the death of Alexander II. The German bishops, who feared the effect of those reforms of which his name was a guarantee, endeavoured to prevent the Emperor Henry IV. from assenting to the election; but Henry gave his approval, and the new pope was crowned, July 10, 1073. From the date of his election the pontificate of Gregory was one life-long struggle for the assertion of the principles with which he believed the welfare of the church and the regeneration of society itself to be inseparably bound up. Regarding as the great evil of his time the thoroughly secularised condition of the church in a great part of Europe, and especially in Germany and northern Italy, he directed against this all his efforts. The position occupied by the higher clergy as feudal proprietors, the right claimed by the crown of investiture with the temporalities of benefices, the consequent dependence of the clergy upon the sovereign, and the temptation to simony which it involved were, in the mind of Gregory, the cause of all the evils under which Europe was groaning; and of all these he regarded Investiture (q.v.) as the fountain and the source. While, therefore, he laboured by every species of enactment, by visitations, by encyclical letters, and by personal exhortations, precepts, and censures, to enforce the observance of all the details of discipline—celibacy, the residence of the clergy, the instruction of the people—and to repress simony and pluralism, it was against the fundamental abuse of investiture that his main efforts were directed. In the year after his election he prohibited this practice, under pain of excommunication both for the investor and the invested, and in the following year he actually issued that sentence against several bishops and councillors of the empire. The Emperor Henry IV. disregarding these menaces and taking the offending bishops under his protection, Gregory cited him to Rome to answer for his conduct. Henry's sole reply was a haughty defiance; and in a diet at Worms in 1076 he formally declared Gregory deposed from the pontificate. The pontiff was not slow to retaliate by a sentence of excommunication; and in this sentence, unless revoked or removed by absolution in twelve months, by the law of the empire at the time, was involved the forfeiture of all civil rights, and deposition from every civil and political office. Henry's Saxon subjects appealing to this law against him, he

was compelled to yield, and by a humiliating penance, to which he submitted at Canossa (q.v.) in January 1077, he obtained absolution from the pope in person. This submission, however, was but feigned; and on his subsequent triumph over his rival, Rudolf of Swabia, Henry resumed hostilities with the pope, and in 1080 again declared him deposed, and caused to be appointed in his place the antipope Guibert, Archbishop of Ravenna, under the name of Clement III. After a protracted siege of three years, Henry, in the year 1084, took possession of Rome. Gregory shut himself up in the castle of St Angelo. Just, however, as he was on the point of falling into his enemy's hands, Robert Guiscard, the Norman Duke of Apulia, entered the city, set Gregory free, and compelled Henry to return to Germany; but the wretched condition to which Rome was reduced obliged Gregory to withdraw first to Monte Cassino and ultimately to Salerno, where he died, May 25, 1085. His dying words are a deeply affecting but stern and unbending profession of the faith of his whole life, and of the profound convictions under which even his enemies acknowledge him to have acted—'I have loved justice and hated iniquity; therefore I die an exile.'

The character of Gregory VII. and the theory of church-polity which he represents are differently judged by the different religious schools; but his theory is confessed by all, even those who most strongly reprobate it as an excess, to have been grand in its conception and unselfish in its object. 'The theory of Augustine's city of God,' says Milman, 'no doubt swam before his mind, on which a new Rome was to rise and rule the world by religion.' In his conception of the constitution of Christian society the spiritual power was the first and highest element. It was to direct, to command the temporal, and, in a certain sense, to compel its obedience; but, as the theory is explained by Fénelon, by Gosselin, and other modern Catholics, the arms which it was authorised to use for the purpose of coercion were the arms of the spirit only. It could compel by penalties, but these penalties were only the censures of the church; and if in certain circumstances temporal forfeitures (as in the case of Henry IV.) were annexed to these censures, this, it is argued, was the result of the civil legislation of the particular country, not of any general ecclesiastical law. Thus, in the case of Henry, the imperial crown was forfeited, according to the Swabian code, by the mere fact of the emperor's remaining for twelve months under excommunication without obtaining absolution from the sentence. Moreover, whatever may be said of the power in itself, or of the lengths to which it has at times extended, the occasion and the object of its exercise in the hands of Gregory were always such as to command the sympathy of the philosophical student of the history of the middle ages. By his firm and unbending efforts to suppress the unchristian vices which deformed society, and to restrain the tyranny which oppressed the subject as much as it enslaved the church, he taught his age 'that there was a being on earth whose special duty it was to defend the defenceless, to succour the succourless, to afford a refuge to the widow and orphan, and to be the guardian of the poor.' Dean Milman sums up his history of Gregory VII. as of one who is to be contemplated not merely with awe, but in some respects, and with some great drawbacks, as a benefactor of mankind.

See Milman's *Latin Christianity* (vol. iii.); Giesebrecht, *Geschichte der Deutsch. Kaiserzeit* (vol. iii.); Bowden, *Life of Gregory VII.* (1840); Voigt, *Hildebrand als Papst* (2d ed. 1846); Gfrorer, *Papst Gregor VII.* (7 vols. 1859–61); W. R. W. Stephens, *Hildebrand and his Times* (1888); and the studies by Soltl (1847), Villemain (1872; Eng. trans. 1873) Langeron (1874), and Meltzer (1876). His whole literary remains are included within seven books or *Registers* of letters, which have been often printed.

Gregory XIII., Ugo Buoncompagno, was born at Bologna, January 7, 1502. He was educated in his native city, where he filled the chair of Law for several years. Having settled at Rome in 1539, he was distinguished by several important employments, and was one of the theologians of the Council of Trent; on his return thence he was created cardinal in 1565, and sent as legate to Spain. On the death of Pius V. Gregory was elected pope in 1572. Not one among the post-Reformation pontiffs has surpassed Gregory XIII. in zeal for the promotion and improvement of education; a large proportion of the colleges in Rome were wholly or in part endowed by him; and his expenditure for educational purposes is said to have exceeded 2,000,000 Roman crowns. The most interesting event of his pontificate, in a scientific point of view, is the correction of the Calendar (q.v.), which was the result of long consideration, and was finally made public in 1582. Under his care was published also a valuable edition of the *Decretum Gratiani* with learned notes. He was a zealous patron of the Jesuits, and supported the League in France against the Huguenots; and it was he who ordered a *Te Deum* in Rome on occasion of the massacre of St Bartholomew, and had a medal struck in honour of the occasion. He strongly supported Philip II. of Spain in his designs against England; and he left the mark of his energy on almost every department of church life and work. He died in 1585, in the eighty-third year of his age.

Gregory, St, surnamed Illuminator (Armenian *Lusavoritch*, Gr. *Phōtistēs*), was of the royal Parthian race of the Arsacidæ, and son of Anak, murderer of Chosrov I., king of Armenia. For this crime his whole family was slain save himself. He owed his escape to a Christian nurse, who secretly conveyed him, when he was two years old, to Cæsarea, in Cappadocia, her native town. He there married a Christian, who bore him two sons, and soon afterwards became a nun. Gregory proceeded to Rome, and entered the service of Terdat, Chosrov's son. After Terdat (Tiridates III.) had, with the help of the Romans, recovered his father's kingdom (286), Gregory, for his refusal to crown with garlands the statue of Anahit, tutelary goddess of Armenia, was thrown by Terdat into a deep pit, where a pious widow nourished him for fourteen years. About the end of that time Terdat was visited with the punishment of Nebuchadnezzar. Healed and baptised by Gregory, he became a zealous Christian, and established Christianity by force throughout his dominions. Gregory was consecrated bishop and head of the Armenian Church by Leontius, Archbishop of Cæsarea, and erected a great number of churches, monasteries, hospitals, and schools in which the sons of heathen priests were trained for the Christian priesthood, whereby a strongly national stamp was given to the church in Armenia. Having resigned the patriarchate in favour of his second son Aristaces, Gregory in 331 retired to a cave at the foot of Mount Sebuh in Upper Armenia, where he died in a few years. The patriarchate was held for many years by his descendants.

The sources for the history of Gregory, which is partly legendary, are two early Armenian histories written by Agathangelos and by Simeon Metaphrastes. A French translation of the former by Victor Langlois appears in vol. i. of the *Historiens de l'Arménie* (1867); the latter (evidently drawn from the former) is given in vol. cxv. of Migne's *Patrol. Græc.* The former was known to

Moses of Khorene, the Herodotus of Armenia, who flourished in the 5th century. The best edition of his work was printed at Venice in 1865; a Latin translation by the brothers Whiston appeared at London in 1736; a French by Levaillant de Florival at Paris in 1841. See S. C. Malan's Eng. translation (1868) of the life of Gregory, from the Armenian work of the Vartabed Matthew published at Venice, 1749.

Gregory Nazianzen was, by his own account, born about 330, at Arianzus, a village near Nazianzus, in Cappadocia, not far from Cæsarea. His father, whose name also was Gregory, and who had originally belonged to the heathen sect of Hypsistarians, worshippers of the Most High, but also of the fire, like the Persians, and keepers of the Jewish Sabbath and the law of the purity of meats, had, chiefly through the influence of his pious wife Nonna, become a convert to Christianity about the time of the great Nicene Council (325), and four years later was raised to the dignity of Bishop of Nazianzus. Formed to piety by domestic example, Gregory was at an early age sent to Cæsarea in Palestine, where the study of eloquence then flourished. He next attended the schools of Alexandria, and subsequently (about 348 to 358) of Athens, where he met Basil the Great, then also a young student, and became his most intimate friend. At the same time there studied at Athens Julian, later emperor and apostate, and there is no doubt that the three often met and had friendly discussions on the subjects of their common studies; although Gregory, even at that time, augured no good for Julian, who exhibited signs of 'an unsettled and arrogant mind.' Gregory, having made brilliant progress in eloquence, philosophy, and sacred literature, returned to Nazianzus, and in 360 received baptism at the hands of his own father, consecrating to God, at the same time, all 'his goods, his glory, his health, his tongue, and his talents;' and, in order to be still more able to pursue a life of austere devotion, he took up his abode with Basil in the desert near the river Iris, in Pontus. Recalled by his father, Gregory was ordained priest, but afterwards fled. Being recalled a second time, he returned to Nazianzus, assisted his father in the ministry, and preached to the people. In 371 or 372 St Basil, who in the meantime had become Bishop of Cæsarea, prevailed upon him to accept the see of Sasima, a small town in Cappadocia. But he had scarcely taken possession of his new dignity, when, overcome again by his innate repugnance to public life, he retired, a bishop without a bishopric, to Nazianzus, where he stayed until the death of his father in 374. He then went into a monastery at Seleucia, which, however, after the death of the Emperor Valens (378), he was induced to leave, in order to undertake the charge of a small Nicene congregation in Constantinople, where until then Arianism had held undisputed sway. Gregory was after a short time, when his erudition and eloquence became conspicuous, elected archbishop, upon which the Arians became so exasperated that his very life was in danger. Gregory, although upheld by Pope Damasus and the Emperor Theodosius, preferred resigning his see voluntarily, 'in order to lay the storm, like another Jonah, although he had not excited it.' He went back to Nazianzus, and took up his solitary abode near Arianzus, where, after some years of a most ascetic life, he died in 389. His ashes were conveyed to Constantinople, and thence, during the Crusades, to Rome. His day is, with the Latins, the 9th of May. His character and temper, ardent and enthusiastic, but at the same time dreamy and melancholy, hard, but also tender, ambitious and yet humble, and all his instability and vacillation between a life of contemplation and of action, are vividly depicted in his writings. These mostly serve the great aim of his life—to uphold the integrity of Nicene orthodoxy against the heresies of the Arians and Apollinarists. The merits of his writings are very unequal, sometimes rising to sublime flights of poetical genius, and displaying classical elegance and refinement, at other times redundant, pedantic, and heavy with far-fetched similes. Yet Gregory may fairly be pronounced one of the first orators and most accomplished and thoughtful writers of all times. His surviving works consist chiefly of about 45 sermons, 243 letters, and 407 poems (dogmatic and moral poems, prayers and hymns, autobiographic and historical poems, epitaphs, and epigrams). The poems were separately printed in a beautiful Aldine edition at Venice in 1504. The first edition of his complete works appeared at Basel in 1550, folio. All the earlier editions were set aside by the great and long-delayed edition that appeared under the auspices of the Benedictines, in 2 vols. (Paris, 1778-1842). The first volume was finally edited by Clemencet; the second by Caillou. His separate works have frequently been edited, and partly translated into different tongues.

See monographs by Ullmann (1825; Eng. trans. 1851; 2d ed. Gotha, 1867) and by A. Benoit (Paris, 1876); and Montant's *Récits critiques* (1878).

Gregory of Nyssa, the younger brother of Basil the Great. After being educated by Basil, he showed an inclination to become a teacher of eloquence, but by the influence of Gregory Nazianzen was prevailed upon to devote himself to the church. Though married, he was in 371 or 372 consecrated by Basil bishop of the little town of Nyssa, in Cappadocia. During the persecution of the adherents of the Nicene Creed in the reign of Valens, Gregory was, at the instigation of the governor of Pontus, deposed by a synod held in Galatia, on the pretext that he had wasted the church's goods. He made his escape, and after the death of Valens was joyfully welcomed back by his flock (378). He was present at the Council of Constantinople in 381, and (along with two other bishops) was appointed to the general oversight of the diocese of Pontus both by the council and by a decree of his friend Theodosius, by whom he had been called 'the common pillar of the church.' He travelled to Arabia and Jerusalem to set in order the churches there, and was again at a synod in Constantinople in 394. He must have died soon afterwards. Of the three Cappadocians Gregory was the greatest speculative theologian, the most faithful to Origenistic views, and not the least zealous defender of Nicene doctrine. He was a less able ruler than Basil, who sometimes lamented his untimely 'good nature' and 'simplicity.' His chief dogmatic work is his *Twelve Books against Eunomius* (the so called 13th book is an independent work). Among his other works are treatises on the doctrine of the Trinity, including *Antirrheticus* (against Apollinaris) and an appeal *To the Greeks, from 'common notions'* (axioms), an attempt to establish the doctrine on grounds of abstract reason; a treatise *On Destiny* (against pagan fatalism); *On the Soul and Resurrection* (ed. Krabinger, Leip. 1837), in the form of a dialogue with his sister Makrina on her deathbed; several ascetic treatises, many sermons, and 23 epistles. In his great *Catechetical Discourse* (ed. Krabinger, Munich, 1838), which was written to convince educated heathens and Jews, he argues that the incarnation is the best possible form of redemption, as manifesting the four chief attributes of God—his omnipotence, mercy, wisdom, and justice. God alone *is*, and all turning away from God to the things of sense (things without being) is death. Christ did not assume a single human nature, but human nature itself in its entirety. 'His return from death is for the mortal race the

beginning of their return to eternal life.' His incarnation is of cosmical significance, and extends to the whole spiritual creation, bringing the whole universe into harmony. 'Not only among men is he born man, but (with absolute consistency) coming also into being among angels he brings himself down to *their* nature' (*Discourse on the Ascension of Christ*). 'By this,' says Harnack, 'the incarnation is resolved into a necessary cosmical process; it becomes a special case of the omnipresence of the Deity in his creation. Alienation from God is as much included in the plan of the Kosmos as is restitution to him. Gregory helped to hand on to later times the pantheistic thought which he never himself conceived clearly and apart from the historical. There is a real kinship between him and the pantheistic Monophysites, the Areopagite, Scotus Erigena, and even the modern "liberal" theologians of Hegelian dye.'

His works were edited by Fronton du Duc (Paris, 1615; reprinted 1638), and more completely in Migne's *Patrologia* (series Græca, vols. xliv. xlvi.). A beginning was made towards a good critical edition by G. H. Forbes (Burntisland, 1855) and Fr. Oehler (Halle, 1865). The latter has published a selection with a German translation (4 vols. Leip. 1858–59). See J. Rupp's monograph on Gregory (1834); H. Weiss, *Die drei grossen Cappadocier* (1872); and Harnack, *Dogmengeschichte*, vol. ii. (1888).

Gregory of Tours, the 'father of Frankish history,' was born about 540 at Arverna (now Clermont), the chief town of Auvergne, and belonged to one of the most distinguished Roman families of Gaul. Originally called Georgius Florentius, he assumed the name Gregory out of respect for his mother's grandfather, Gregory, Bishop of Langres. He was educated by his uncle, Gallus, Bishop of Clermont, and after his death by Avitus, a priest of his native town. His recovery from a severe sickness, through a pilgrimage to the grave of St Martin of Tours, led Gregory to devote himself to the service of the church, and by the choice of the clergy and people and favour of Sigbert, king of Austrasia, to whom Auvergne had fallen on the death of Clothar I. in 561, he became Bishop of Tours in 573. He gave himself zealously to his sacred office and the public good. In the struggles between Sigbert and his wife Brunhilda on the one side against Chilperic and his wife Fredegond on the other he took the side of the former, and in the vicissitudes of a conflict in which Tours frequently changed masters had to suffer many persecutions. After the death of Chilperic, whom Gregory calls 'the Nero and Herod of our time,' he enjoyed great influence over his successors, Guntram and Childebert II. He died 17th November 594. The fame of Gregory rests on his *Historiæ sive Annalium Francorum libri x.*, the chief authority for the history of Gaul in the 6th century. It begins with a summary of universal history, but by the end of book i. reaches the Frankish conquest and the death of St Martin. From this point onwards the narrative is written with much greater fullness, the last seven years (585–91) extending to four books. Gregory himself laments his unskilfulness in writing—his wrong genders and cases, and misused prepositions. His ten books are the artless memoranda of a contemporary, bearing on their face the clear stamp of truth. It is entirely to him that we owe our exact knowledge of the dark and stormy times of the Merovingian kings.

Besides his *History*, he wrote *Miraculorum libri vii.*, a hagiographical compilation, including four books on the innumerable miracles of St Martin. A critical edition of his works was published by Ruinart in 1699 (1 vol. folio), and in Migne's collection (vol. lxxi.). Of the History the best editions are by Guadet and Taranne (1836–38), and that in the *Monumenta Germaniæ Historica* (1884–85). French translations are by H. L. Bordier (2 vols. 1859–61) and that edited by Jacobs (2 vols. 1861); there is a German translation by W. Giesebrecht (1851; 9th ed. 1873). The historical material supplied by Gregory is reproduced in Thierry's *Récit des Temps Mérovingiens* (Paris, 1840). A French translation of the *Books of Miracles* and lesser writings was published by H. L. Bordier (4 vols. 1857–64). See Lobell, *Gregor von Tours und seine Zeit* (1839; 2d ed. 1869); G. Monod, *Études critiques sur les sources de l'Histoire Mérovingienne* (Paris, 1872); and vol. i. of Mark Pattison's *Essays* (1889).

Gregory Thaumaturgus ('wonder-worker'), a celebrated disciple of Origen, and the apostle of the Christian church in Pontus. He was born about 210, of wealthy heathen parents at Neocæsarea, in Pontus, and was originally named Theodorus. His early education was for the practice of law, but, coming under the influence of Origen at Cæsarea in Palestine, he was his disciple for about eight years, with an interruption caused by the persecution under Maximin the Thracian, during which he probably studied at Alexandria. Origen, in a letter to him, expressed the wish that he would 'spoil the Egyptians' by placing the intellectual treasures he gathered from the Greeks in the holy service of Christian philosophy. After this he produced his *Panegyricus* on Origen, and, returning to his native country, was consecrated Bishop of Neocæsarea by Phædimus, Bishop of Amasea. The influence of Gregory in Asia Minor continued from the middle of the 3d century to far down into the 4th, and its extent may be inferred from the numerous legends of his miracles, and the tradition that at his death (about 270) there were only as many pagans in Neocæsarea as there had been Christians in it at his consecration—viz. seventeen. His celebrated *Ekthesis*, or *Confession of Faith*, said to have been derived by revelation from the Virgin Mary and the apostle John, is a summary of the theology of Origen, and was used as the basis of the instruction given to catechumens at Neocæsarea. It is of the greatest value as a record of the state of the theology at the middle of the 3d century. 'There is scarcely a sentence in it,' says Harnack, 'that recalls to us the Bible; it is a compendium of the sublimest speculation, only in the words "Father," "Son," and "Spirit" reminding us of the gospel.' Its genuineness is disputed, but is ably defended by Caspari. Gregory is said to have contended against Sabellianism, yet in his lost *Argument with Elian* Basil tells us there stood this sentence: 'the Father and the Son are two in idea, but one in essence.' But as Basil also testifies that he spoke of the Son as a 'creature' and a 'work,' the above sentence is probably no more than an Origenistic assertion of the substantial unity of the Deity in opposition to tritheistic views. The genuineness of two other treatises attributed to him, one addressed to Philagrius, on the co-essentiality of the persons in the Godhead, and the other, a dialogue with Theopompus, on the question whether the Deity is capable or incapable of suffering, is undecided. Gregory's works are printed in vol. iii. of Galland's *Bibliotheca Patrum*, and in Migne's collection, vol. x. His *Panegyricus* (which contains an autobiography of its writer) is printed among the works of Origen. A special edition was published by J. A. Bengel in 1722.

See Ryssel, *Gregorius Thaumaturgus, sein Leben und seine Schriften* (Leip. 1880); and Harnack, *Dogmengeschichte*, vol. i. (Freiburg im Breisgau, 1888).

Gregory, the name of a Scottish family distinguished, like that of the Bernouillis, in the history of science.—JAMES GREGORY was born at Aberdeen in November 1638, and studied at Marischal College there. Before completing his twenty-fourth year he invented the reflecting telescope known by his name, and described it in a work entitled *Optica Promota*. In 1665 he

were to the university of Padua, where in 1667 he produced *Vera Circuli et Hyperbolæ Quadratura*, followed in 1668 by *Geometriæ Pars Universalis* and *Exercitationes Geometricæ*. Shortly after his return home he obtained (1669) the professorship of Mathematics at St Andrews, a chair which he filled until his removal to a similar one at Edinburgh in 1674. He died in that city in the following year. To him is also attributed a satirical tract, *Great and New Art of weighing Vanity* (1672). For an account of his works and discoveries, see Hutton's *Philosophical and Mathematical Dictionary*.—DAVID GREGORY, nephew of the above, was born at Aberdeen in 1661, and there received the early part of his education, which was completed at Edinburgh. In his twenty-third year he was appointed professor of Mathematics in the university of the latter city. In 1691, through the friendship of Newton and Flamsteed, he obtained the Savilian professorship of Astronomy at Oxford. He died at Maidenhead in 1708. Among his works may be mentioned *Exercitatio Geometrica de Dimensione Figurarum* (1684); *Catoptrica et Dioptrica Sphærica Elementa* (1695); *Astronomiæ Physicæ et Geometricæ Elementa* (1702), an illustration and defence of Newton's system; and an edition of Euclid in Greek and Latin (1703). He also wrote a treatise on *Practical Geometry* (1745) and many memoirs in the *Phil. Trans.*, vols. xviii.–xxv.—JOHN GREGORY, grandson of James, was born at Aberdeen, 3d June 1724, where he received his early education; afterwards he studied medicine at Edinburgh and Leyden. After filling the chair of Medicine at Aberdeen from 1755, he was appointed in 1766 professor of the Practice of Medicine in Edinburgh, where he died, 9th February 1773. Among his works are *Elements of the Practice of Physic* (1772) and *A Comparative View of the State and Faculties of Man with those of the Animal World* (1765). In 1788 his works were collected in four vols. by Tytler (Lord Woodhouselee), who prefaced them by a life of the author.—His son, JAMES GREGORY, born at Aberdeen in 1753, became in 1776 professor of the Practice of Medicine at Edinburgh, and eventually a leading man in his profession. He died 2d April 1821. He was the author of *Conspectus Medicinæ Theoreticæ* and of two vols. of *Philosophical and Literary Essays* (1792).—This James's son, WILLIAM GREGORY, born 25th December 1803, professor of Chemistry at Glasgow (1837), in King's College, Aberdeen (1839), and at Edinburgh University (1844), is noticeable for his advocacy of Liebig's views in Great Britain. He died 24th April 1858. He wrote *Outlines of Chemistry* (1845), and translated (1855) Liebig's *Principles of Agricultural Chemistry*.—The stomachic and aperient known as Gregory's mixture was compounded by Dr James Gregory, and consists of rhubarb, magnesia, and ginger.

Gregory, OLINTHUS, mathematician and miscellaneous writer, was born at Yaxley, Huntingdon, 29th January 1774, and became a newspaper editor and then a teacher of mathematics successively at Cambridge and Woolwich. At Woolwich he died 2d February 1841. He wrote several works on mathematics, superintended almanacs, edited gentlemen's diaries, and published lives of Robert Hall and Mason Good.

Greifenberg, a town of Prussia, in the province of Pomerania, dating from 1262, is situated 55 miles by rail NE. of Stettin. Pop. 5636.

Greifenhagen, an agricultural town of Prussia, on the Oder, 13 miles by rail SSW. of Stettin. Pop. 6603.

Greifswald, a town of Prussia, in the province of Pomerania, is situated 2½ miles from the mouth of the Ryck and 25 miles by rail SE. of Stralsund. The university, founded in 1456, has 83 professors and 750 students, of whom one-half are medicals. The university is well equipped with medical museums, laboratories, &c.; the library contains about 135,000 volumes. There is a considerable shipping trade. The chief industries include the making of machinery, chains, and railway wagons, the curing of herrings, and iron-founding. Pop. (1875) 18,016; (1885) 20,333. Shortly after being made a town (1250) Greifswald joined the Hanseatic League. At the peace of Westphalia (1648) it came into the possession of Sweden; but, together with the whole of Swedish Pomerania, was ceded to Prussia in 1815. See Pyl's *Geschichte Greifswalds* (1879).

Greisen, a rock composed essentially of quartz and mica, but which almost invariably contains topaz. It is met with in regions where tin ores abound, and is believed to be a granite which has been metamorphosed in connection with exhalations of fluoric acid.

Greiz, capital of the German principality of Reuss-Greiz, and seat of the sovereign prince, is situated on the White Elster, 47 miles SSW. of Leipzig. It contains three castles and a 13th-century church, and manufactures cotton and woollen goods, also cashmere and shawls, and possesses dye-works and linen-printing establishments. Pop. (1875) 12,657; (1890) 20,141. The town was severely ravaged by fire in 1494, and again in 1802.

Grenada, an island of volcanic origin in the British West Indies, lying N. by W. from Trinidad, mountainous and picturesque, with an area of 133 sq. m. Some of the craters in the central ridge of mountains, rising to 3000 feet, have been transformed into large lakes. Streams and mineral springs abound. There are several good natural harbours, that of St George (pop. 4000), the capital of the island and the headquarters of the government of the Windward Islands, being accounted one of the best in the West Indies, though it is not now much used. The inhabitants, 42,403 in 1881, and 54,062 in 1891 (mostly negroes, with 2118 coolies), cultivate cocoa, coffee, and oranges. Further, a little rum is manufactured, and spices and fruits are grown. Exports, £280,000 a year; imports, £170,000. Grenada has been a crown colony since 1885; previous to that date it had a constitutional government. Columbus was the discoverer of the island in 1498. In the words of Mr Froude, Grenada was 'the home for centuries of man-eating Caribs, French for a century and a half, and finally, after many desperate struggles for it, was ceded to England at the treaty of Versailles' (1783).

Grenade, a small shell exploded by a time-fuse, about 3 inches in diameter, of iron or annealed glass, filled with powder, and thrown from the hand. They are chiefly used against the dense masses of troops assembled in the ditch of a fortress during an assault, and then are often rolled over the parapet through wooden troughs instead of being thrown by hand.

Grenadier, originally a soldier who was employed in throwing hand-grenades, and then a member of the first company of every battalion of foot, in which the tallest and finest men were placed. This company used to be distinguished by tall bearskin caps, and held the place of honour—viz. the right when in line, and the front when in column. In the British army the name is now only used as the title of the first three battalions of the foot-guards.

Grenadines, a chain of islets in the West Indies, extending between Grenada, on which they

are chiefly dependent, and St Vincent, with a total area of 13 sq. m., and about 7300 inhabitants. The largest is Carriacou, with nearly 11 sq. m.; pop. 6000.

Grenelle, a south-western suburb of Paris.

Grenoble (Lat. *Gratianopolis*), since 1839 a first-class fortified city of France, capital of the department of Isère, is finely situated in a beautiful valley 59 miles SE. of Lyons. It is divided by the Isère into two unequal portions, connected by three bridges. The 15th-century cathedral of Nôtre Dame, St Laurent, St André (with Bayard's monument, transferred hither in 1822), and the Gothic *palais-de-justice* are the most interesting buildings. The town has a university of three faculties, with about 275 students, and numerous other educational establishments, including an industrial school and a school of forestry. The library contains 170,000 volumes and 7500 MSS. The staple industry is the manufacture of kid gloves (employing 22,000 persons in 115 factories). Besides this, there are manufactures of liqueurs (Chartreuse), hats, cement, and hardware, and an active trade in hemp, corn, timber, wine, and cheese. Pop. (1872) 35,280; (1886) 49,338. Grenoble, originally a city of the Allobroges, was fortified by the Romans. It was Burgundian in the 5th century, and in the 11th belonged to the empire. Later on it became the capital of Dauphiné, along with which it passed to France in 1349. The town has been frequently inundated, the flood of 1778 being the most memorable. See Pitot's *Histoire de Grenoble* (2 vols. 1845-46).

Grenville, GEORGE, the English statesman who passed the Stamp Act which first drove the American colonies to resistance, was born on 14th October 1712. He was younger brother to Richard Grenville, Earl Temple (q.v.), and brother-in-law of the Earl of Chatham. He entered parliament in 1741, and from 1744 to 1762 filled several government offices. In 1757 he introduced a bill for the regulation of the payment of the navy. In 1762 he became Secretary of State, and then First Lord of the Admiralty; and in the following year he succeeded Lord Bute as prime-minister, uniting in himself the offices of Chancellor of the Exchequer and First Lord of the Treasury. The most prominent facts of his administration were the prosecution of Wilkes and the passing of the American Stamp Act. He resigned the premiership in 1765, and died 13th November 1770. Although an honest and honourable man, his overleaping ambition, want of tact, and imperious nature made him a highly unpopular minister. See the *Grenville Papers*, edited by W. J. Smith (4 vols. 1852-53).

Grenville, SIR RICHARD, one of England's unforgotten worthies, sprang from an ancient Cornish family, and early distinguished himself under Elizabeth by his courage both on land and sea. He was knighted about 1577, and in 1585 commanded the seven ships which carried out Raleigh's first colony to Virginia, the ill-success of which, according to Ralph Lane, its leader, was mainly due to the commander's tyranny. Linschoten speaks of the fierceness of his temper, and how at table he would crush the glasses between his teeth till the blood ran out of his mouth. Grenville fought and spoiled the Spaniards like other heroes of his time, and while preparing another fleet for Virginia was stayed by the queen at Bideford to take his share in the glory of the Armada fight. In August 1591 he commanded the *Revenge* in Lord Thomas Howard's squadron of six vessels, when they fell in with a Spanish fleet of fifty-three sail off Flores, in the Azores. Grenville took off his ninety sick men from the island, and, while the admiral made good his escape, refused with splendid disobedience 'to turn from the enemy, alleging that he would rather choose to die than to dishonour himself, his country, and her majesty's ship.' The great *San Philip*, of 1500 tons, towering in height above the *Revenge*, soon took the wind from her, and now she found herself in the midst of a ring of enemies, and a battle almost unequalled in the history of the world began. From three in the afternoon, and all through the night till morning the battle raged, the stars above blotted out by the sulphurous canopy of smoke, while as many as fifteen several Spanish ships were beaten off in turns, and no less than 800 shot of great artillery endured. Two ships were sunk by her side, two more so disabled that they soon foundered, while as many as 2000 men were slain or drowned. But the *Revenge* was by this time a helpless wreck, all her powder spent, the pikes broken, forty of her 100 sound men slain, and the most part of the rest hurt, the vice-admiral himself sore wounded, both in the body and in the head. Sir Richard would have had the master-gunner to blow up the ship, but was overborne by his surviving men, and carried on board one of the Spanish ships, where he died of his wounds the second or third day after, with the words on his lips, according to Linschoten's account: 'Here die I, Richard Grenville, with a joyful and quiet mind: for that I have ended my life as a true soldier ought to do, that hath fought for his country, queen, religion, and honour. Whereby my soul most joyfully departeth out of this body, and shall always leave behind it an everlasting fame of a valiant and true soldier, that hath done his duty as he was bound to do.' 'What became of his body,' says Raleigh, 'whether it were buried in the sea or on the land we know not: the comfort that remaineth to his friends is, that he hath ended his life honourably in respect of the reputation won to his nation and country, and of the fame to his posterity; and that, being dead, he hath not outlived his own honour.' A few days after the fight a great storm arose from the west and north-west, in which fourteen Spanish ships, together with the *Revenge* and in her 200 Spaniards, were cast away upon the Isle of St Michaels, besides fifteen or sixteen more upon the other islands. 'So it pleased them to honour the burial of that renowned ship the *Revenge*, not suffering her to perish alone, for the great honour she achieved in her lifetime.' 'Hardly,' says Froude, 'as it seems to us, if the most glorious actions which are set like jewels in the history of mankind are weighed one against the other in the balance, hardly will those 300 Spartans who in the summer morning sat combing their long hair for death in the passes of Thermopylæ have earned a more lofty estimate for themselves than this one crew of modern Englishmen.'

This great exploit was told in noble English by Sir Walter Raleigh in *A Report of the Truth of the Fight about the Iles of Açores, this last Summer* (1591); in good verse by Gervase Markham, in *The Most Honorable Tragedie of Sir Richard Grinuile, Knight* (1595); by Jan Huygen van Linschoten, in his diary (Dutch, 1596; Eng. 1598), the three reprinted together by Arber (1871); by Froude, in 'England's Forgotten Worthies,' in the *Westminster Review* for July 1852, since included in the first volume of his *Short Studies on Great Subjects*; and by Tennyson in *The Revenge*, the noblest heroic ballad in the English tongue—set not unworthily to music in Villiers Stanford's cantata produced at Leeds in 1886.

Sir Richard Grenville was grandfather of the English Bayard, Sir Bevill Grenville (born 1596), the hero of Hawker's spirited ballad, who was killed at the battle of Lansdown, near Bath, 5th July 1643.

Grenville, WILLIAM WYNDHAM, LORD GRENVILLE, third son of George Grenville, was born 25th October 1759. After studying at Eton and Oxford,

he became in 1782 a member of the House of Commons and secretary to his eldest brother, Earl Temple (afterwards Marquis of Buckingham), just appointed Lord-lieutenant of Ireland. Soon after he became Paymaster-general of the Army, and in 1789 was chosen Speaker of the House of Commons. But in 1790, on his appointment as Secretary of State for the Home Department, he was raised to the peerage with the title of Baron Grenville. He became Foreign Secretary in the ensuing year. He resigned office, along with Pitt, in 1801, on the refusal of George III. to give his assent to the Catholic Emancipation Bill, of the aims of which Grenville was one of the principal supporters. In 1806 he formed the government of 'All the Talents,' which, before its dissolution in the following year, passed the act for the abolition of the slave-trade. From 1809 to 1815 he acted along with Earl Grey, and he generally supported Canning. Lord Grenville was an able speaker and an excellent scholar, and, though he was not of first-rate abilities, his conscientiousness, industry, and knowledge of affairs gave him much influence among the peers and as a statesman. He died at Dropmore, Buckinghamshire, 12th January 1834.

Grenville-Murray. See MURRAY.

Gresham, SIR THOMAS, founder of the Royal Exchange, was born in 1519, the only son of Sir Richard Gresham, an opulent merchant of Norfolk ancestry, who in 1537 was elected Lord Mayor of London. Apprenticed awhile to his uncle, Sir John Gresham, a wealthy London mercer, and then sent to study at Gonville Hall, Cambridge, in 1543 he was admitted a member of the Mercers' Company, and in 1551 was employed as 'king's merchant' at Antwerp. In two years he paid off a heavy loan, entirely restored the king's credit, and introduced a new system of finance. As a Protestant, he got his dismissal from Queen Mary, but, on presenting a memorial of his past services, was soon reinstated. By Queen Elizabeth he was in 1559 knighted and appointed for a short time English ambassador at the court of the regent at Brussels. The troubles in the Netherlands compelled him, in 1567, to withdraw finally from Antwerp, to which city he had made more than forty journeys on state service; in one, in 1560, he was thrown from his horse and lamed for life. In 1569, by his advice, the state was induced to borrow money from London merchants, instead of from foreigners, to the great advantage of the mercantile body. Having in 1564 lost his only son, Richard, in 1566–71 he devoted a portion of his great wealth to the erection of an Exchange (q.v.), in imitation of that of Antwerp, for the London merchants, who were wont to meet in the open air. Renowned for his hospitality and liberality, he frequently entertained foreign personages of distinction, and erected a magnificent mansion at Osterly Park, near Brentford, where he was visited by Queen Elizabeth. For the endowment of a college in London he directed by his will that his town-mansion in Bishopsgate Street should be converted into a residence and lecture-rooms for seven professors, to be salaried out of the Royal Exchange revenues. Gresham College gave place to the Excise Office in 1768, and the lectures were delivered in a room in the Exchange till 1843, when the lecture-hall in Basinghall Street was built out of the accumulated fund. The subjects of lectures (all of which since 1876 are delivered in English only, not Latin) are divinity, physic, astronomy, geometry, law, rhetoric and music. Gresham also provided for the erection and support of eight almshouses, and made many other charitable bequests. He died suddenly, 21st November 1579. See his Life by Dean Burgon (2 vols. 1839). For Gresham's Law, see BIMETALLISM.

Gretna Green, a village of Dumfriesshire, near the head of the Solway Firth, 10 miles NNW. of Carlisle. After the abolition of Fleet marriages by Lord Hardwicke's Act (1754), English persons wishing to marry clandestinely had to get out of England, to which alone that act had reference. Thus the practice arose of crossing the Border into Scotland, where Gretna Green, or Springfield, as the first village, had by 1771 become, in Pennant's words, 'the resort of all amorous couples whose union the prudence of parents or guardians prohibits.' The 'priest' or 'blacksmith' might be any one—ferryman, toll-keeper, or landlord; his fee might be anything from half a guinea to £100; and 'church' was commonly the toll house till 1826, and afterwards Gretna Hall. At the toll-house nearly 200 couples were sometimes united in a twelvemonth. Coldstream and Lamberton, in Berwickshire, were chapels-of-ease to Gretna for the eastern Border, as also till 1826 was Portpatrick, in Wigtownshire, for Ireland. One of the earliest Scottish runaway matches on record is Richard Lovell Edgeworth's (1763); amongst his successors were Lords Brougham, Dundonald, Eldon, and Erskine, besides numerous scions of the noble families of Villiers, Fane, Beauclerc, Coventry, Paget, &c. In 1856 all irregular marriages were rendered invalid unless one of the parties had been residing in Scotland for three weeks previously; this proviso observed, a Gretna Green marriage is still possible. See P. O. Hutchinson's *Chronicles of Gretna Green* (2 vols. 1844).

Grétry, ANDRÉ ERNEST MODESTE, composer, was born at Liège, 8th February 1741, studied at Rome, and settled at Paris, where he became famous as author of more than forty comic operas, of which *Le Huron* (1768) and *Lucile* (1769) were the earliest, and *Raoul* and *Richard Cœur-de-Lion* among the best known. He was made inspector of the Conservatoire, and a member of the Institute; later a pension from Napoleon enabled him to retire to Ermenonville, where, in Rousseau's old house, he died, 24th September 1813. His operas are noted for their rich and bright melody, and did much to form the musical taste of the time. He also wrote *Mémoires* (4 vols. Paris, 1796). See the Lives by Gregoir (1883) and Brenet (1884).

Greuze, JEAN BAPTISTE, genre- and portrait-painter, was born at Tournus, near Macon, on 21st August 1725. He received instruction in art from Grandon, a painter of Lyons, who took him to Paris, where he studied in the life-school of the Academy, and produced a subject-picture of such excellence—'A Father explaining the Bible to his Children'—that much doubt was expressed as to its being the work of so young an artist. His skill, however, was amply proved by productions which followed, and his 'Blind Man Cheated' procured his admission as an Associate of the Academy in 1755. In that year he visited Italy with the Abbé Gougenot, and on his return exhibited in 1757 several Italian subjects, but having failed to comply with the regulations of the Academy he was interdicted from contributing to the salon. Having painted in 1769 his 'Severus reproaching Caracalla,' now in the Louvre, he was readmitted as a genre-painter, instead of to the higher class of historical painters, and upon this he indignantly withdrew. He was the friend of Diderot, who praised his productions in his criticisms of the salon; but in the days of the Directorate and the classical revival of David his works were little esteemed; and he died in poverty in Paris, 21st March 1805. His art possesses charming qualities of delicacy and grace, but is marred by its triviality, by the insincerity of its sentiment, and by its pursuit of mere prettiness. He is seen at his best

in his domestic interiors with figures, and especially in such fancy studies of girls as 'The Broken Pitcher' in the Louvre, the 'Innocence' and 'Girl with Doves' in Sir Richard Wallace's collection, and 'Girl with Dead Canary' in Scottish National Gallery. See monograph by Normand (1892).

Greville, Charles Cavendish Fulke, writer of memoirs of his time, the eldest son of Charles Greville by his wife, Lady Charlotte Cavendish Bentinck, was born in 1794. He was educated at Eton and at Christ Church, Oxford. Before he was twenty he was appointed private secretary to Earl Bathurst. In 1821 he became Clerk of the Council in Ordinary, an office which he discharged until 1860. During the last twenty years of his life he occupied a suite of rooms in the house of Earl Granville, in Bruton Street, and there he died, 18th January 1865. In advocacy of the completion of the measure of relief to the Catholics by the payment of their clergy he wrote *Past and Present Policy of England towards Ireland* (1845). His position as Clerk of the Privy-council brought him into intimate relations with the leaders of both political parties, and gave him peculiar facilities for studying court life from within—advantages which the shrewd intelligence and cultured versatility of Greville turned to the best account by penning miscellaneous memoirs dealing alike with public and private affairs, and containing many lively, immediate sketches of the distinguished personages of his time, political, social, and literary. The first part of the *Memoirs*, covering the reigns of George IV. and William IV., edited by Mr Reeve, appeared in 1875. The second part, embracing the period 1837–51, was published in 1885; and the third, 1852–60, in 1887.

Greville, Sir Fulke, poet and friend of much greater poets than himself, was born of a good Warwickshire family in 1554. He studied at Cambridge, travelled abroad, made a figure at court, was knighted in 1597, and created Lord Brooke in 1620. He was murdered in an altercation with his serving-man, 30th September 1628. Several didactic poems, more than a hundred sonnets, and two tragedies were printed in 1633; his Life of Sir Philip Sidney in 1652. Grosart edited his works (4 vols. 1870), and published a selection (*The Friend of Sir Philip Sidney*) in 1895.

Gréville, Henry, the pseudonym of Madame Alice Durand (*née* Fleury), who was born at Paris, 12th October 1842, accompanied her father when he was called to a chair at St Petersburg in 1857, and there married Émile Durand, a French professor of law, with whom she returned to France in 1872. Already at St Petersburg she had contributed romances to the journals; when at Paris she began to issue with almost too great rapidity a series of novels, often bright, vigorous, and original in their pictures of Russian society, but unequal, occasionally feeble, and sometimes even not free from the one fatal fault of dullness. *Dosia* (1876) received from the Academy the Montyon prize, and was followed by *La Princesse Ogheroff* (1876), *Les Koumiassine* (1877), *Suzanne Normis* (1877), *La Maison Maurice* (1877), *Les Epreuves de Raissa* (1877), *L'Amie* (1878), *Un Violon Russe* (1879), *Lucie Rodic* (1879), *Le Moulin Frappier* (1880), *La Cote Monard* (1880), *Perdue* (1881), *Madame de Dreux* (1881), *Rose Rozier* (1882), *Un Crime* (1884), *Louis Breuil* (1883), *Idylles* (1885), and *Cléopâtre* (1886).

Grévy, François Paul Jules, President of the French Republic, was born at Mont-sous-Vaudrey, in the Jura, August 15, 1807. He studied law in Paris, and was admitted an advocate, acquiring distinction as the defender of republican political prisoners. After the Revolution of 1848 he was commissary of the provisional government in his native department, for which also he was returned to the Constituent Assembly. While preserving an independent attitude, he usually voted with the Left, and his ability as a speaker soon brought him into prominence. He became Vice-president of the Assembly, and took a leading part in the constitutional debates. He opposed the government of Louis Napoleon, and condemned the expedition to Rome. After the *coup d'état* he retired from politics and confined himself to the bar, but in 1869 he was again returned as deputy for the Jura. He denounced the Second Empire during its closing days, and in February 1871 was elected President of the National Assembly, being re-elected in 1876, 1877, and 1879. The Monarchists were triumphant from 1873 to 1876, but their schemes were trenchantly attacked by Grévy, who likewise published a pamphlet entitled *The Necessary Government*. Upon the resignation of Marshal MacMahon in 1879 Grévy was elected President of the Republic for seven years, securing 563 votes out of a total of 713. Although his presidency was not brilliant, it was frequently marked by much tact, as on the occasion of the hostile demonstration against the king of Spain, on his visit to Paris in 1883. The republic was consolidated and strengthened at home, but the foreign policy of France was inglorious, and in March 1885 President Grévy closed the Tonkin difficulty by concluding peace with China upon his own initiative. In December 1885 Grévy was elected president for a further period of seven years, but, hampered by ministerial difficulties, resigned in December 1887. He died at Mont-sous-Vaudrey, 9th September 1891.

Grewia, a genus of Tiliaceous trees yielding good bast for ropemaking, &c. in the East Indies. Some yield timber, and others their leaves as fodder.

Grey, Charles, Earl, statesman, was born at Falloden, Northumberland, 15th March 1764, and educated at Eton and Cambridge. On attaining his majority he was returned to parliament as member for Northumberland in the Whig interest, and ultimately succeeded to the leadership of the party. He was one of the managers of the impeachment of Warren Hastings, and in 1792 helped to found the Society of the Friends of the People, whose object was the reform of the representative system. Taking advantage of the alarm caused by the French Revolution, Pitt suppressed the society, and at a later period Grey expressed regret for his share in the movement. Grey introduced the futile motion for the impeachment of Pitt, and took a prominent part in the temporary 'secession' of the Whigs from a parliament which was hostile to reform, and which he and his friends maintained did not represent the nation. He also strongly denounced the union between England and Ireland. On the advent of the Fox-Grenville administration in 1806, Grey, now Lord Howick, was appointed First Lord of the Admiralty, and on the death of Fox he became Foreign Secretary and leader of the House of Commons. Grey was compelled by circumstances to continue the war policy of Pitt. To his honour he carried through parliament the act abolishing the African slave-trade introduced by Wilberforce in 1807. The king quarrelled with his ministers on the Catholic relief question, and as Grey declined to give a promise not to press forward a measure for absolving Roman Catholics in the army and navy from the oath, the government was broken up.

In 1807 he succeeded his father as second Earl Grey. He ably led the Opposition for a period of

eighteen years after the death of Perceval. He opposed the renewal of the war in 1815; denounced the coercive measures of the government against the people; condemned the bill of pains and penalties against Queen Caroline; defended the right of public meeting; and supported the enlightened commercial policy of Huskisson. He declined to lend any aid to Canning in 1827. Two years later he had the gratification of seeing the Catholic Emancipation Act carried. On the fall of the Wellington administration in 1830, Grey accepted the commands of William IV. to form a government in which he became prime minister and First Lord of the Treasury. It was understood that parliamentary reform was to be treated as a cabinet question, and the new premier announced in the House of Lords that the policy of his administration would be one of peace, retrenchment, and reform. The first reform bill was produced in March 1831, but its defeat led to a dissolution and the return of a House of Commons still more thoroughly devoted to the cause of reform. A second bill was carried, which the Lords threw out in October, and riots ensued in various parts of the country. Early in the session of 1832 a third bill was carried in the Commons by an enormous majority, and it weathered the second reading in the Upper House; but when a motion by Lord Lyndhurst to postpone the disfranchising clauses until the enfranchising clauses had been discussed was adopted, ministers resigned. The Duke of Wellington was charged to form an administration, but upon his failure Grey returned to office with power to create a sufficient number of peers to carry the measure. Wellington now withdrew his opposition, and on the 4th of June the Reform Bill passed the House of Lords. Grey was the chief of a powerful party in the first reformed parliament, but he was not destined long to remain at the head of affairs. One other great measure, the act for the abolition of slavery in the colonies, he carried, as well as a number of minor reforms; but dissensions sprang up in the cabinet, and in consequence of his Irish difficulties Grey resigned office in July 1834. He now ceased to take any active part in politics, and spent his closing years chiefly at Howick, where he died, 17th July 1845. Grey was a chivalrous, able, and high-minded man. While not in the first rank of parliamentary orators, his speeches on those subjects in which he was deeply interested frequently attained to real eloquence. Though he was the leader of the aristocratic Whigs, his greatest claim to remembrance in history is the fact that he opened the portals of the Constitution to the people. See George Grey, *Life and Opinions of the second Earl Grey* (1861).

His son HENRY GREY, third Earl, was born December 28, 1802. He was educated at Trinity College, Cambridge, and in 1826, as Lord Howick, was returned to the House of Commons for Winchelsea. He next sat for a brief period for Higham Ferrers, and after the passing of the Reform Bill of 1832 was elected for North Northumberland. He was appointed Under-secretary for the Colonies in his father's ministry, but retired in 1833 because the cabinet would not support the immediate emancipation of the slaves. He subsequently held for a short time the post of Under-secretary in the Home Department, and in Melbourne's administration of 1835 became Secretary for War. In 1841 he was rejected for Northumberland, but returned for Sunderland, and now opposed Peel's policy. He succeeded his father in the peerage in 1845, and in the following year entered Lord John Russell's cabinet as Secretary for the Colonies. After the resignation of the government in 1852, he published his *Defence of the Colonial Policy of Lord Russell's Administration*. He now took his seat on the cross-benches, and never afterwards held office. He opposed the Crimean war, and at a later period condemned the eastern policy of Lord Beaconsfield. He also frequently adopted a hostile attitude towards Mr Gladstone, to whom he was especially opposed at the general election of 1880. For many years past Lord Grey rarely spoke in the House of Lords, but from his retirement he wrote trenchant letters to the *Times* upon public affairs, and notably on colonial questions. In 1858 he issued his *Essay on Parliamentary Government as to Extent*, in 1867 he published his father's *Correspondence with William IV.*; and on various occasions he has printed speeches and letters of his own, including those to the *Times* on 'Free Trade with France,' which appeared in 1881. He died 9th October 1894.

Grey, SIR GEORGE, Baronet, English statesman, was the son of the first baronet, and nephew of the great Reform leader, Earl Grey. Born at Gibraltar, May 11, 1799, he was educated at Oriel College, Oxford, where he took a first-class in classics. He was called to the bar at Lincoln's Inn in 1826, but relinquished the law after succeeding to the baronetcy in 1828. In 1832 he was returned to the House of Commons for Devonport, which he continued to represent for fifteen years. He was appointed Under-secretary for the Colonies in 1834, having already made his mark in parliament, and Lord Melbourne reappointed him to the same office in 1835. For some years his chief speeches were delivered in connection with Canadian affairs and the constitutional difficulties in Jamaica. When Lord John Russell brought in a bill for the temporary suspension of the Lower Canadian constitution, Grey ably defended the measure against Mr Roebuck, who had been heard at the bar in opposition to the bill. In 1839 Grey became Judge-advocate, an office which he exchanged in 1841 for that of Chancellor of the Duchy of Lancaster, but the same year he went out of office with his colleagues. When Lord John Russell became premier in 1846, Grey accepted the onerous post of Home Secretary. During the time of the Chartist disturbances he discharged the difficult duties of his office with vigour and discrimination, this being the culminating point of his career as a practical and administrative statesman. He carried in the teeth of much opposition the Crown and Government Security Bill, a measure providing for the more effectual repression of seditious and treasonable proceedings. The Alien Bill was also under his charge. Owing to Grey's measures in view of the Chartist demonstration in London in 1848, when 150,000 special constables were sworn in, a threatened popular rising was averted. In consequence of the condition of Ireland, Grey carried a measure in 1849 for the further suspension of the Habeas Corpus Act. Three years later the Russell ministry was wrecked on the Militia Bill. At the general election in August 1847 Grey was returned for North Northumberland, but, being defeated at the election in July 1852, he was elected for Morpeth in the following January. In June 1854 he accepted the seals of the Colonial Office, and on the formation of Lord Palmerston's first administration in 1855 took his old post of Home Secretary. He carried an important measure on the subject of secondary punishments, in which the ticket-of-leave system was remodelled. On the return of Lord Palmerston to office in 1859, after his defeat in the previous year on the Conspiracy Bill, Grey was appointed Chancellor of the Duchy of Lancaster; but in 1861 he once more returned to the Home Office. He introduced and carried through several useful measures, including the Prison Ministers Bill. After the death of

Palmerston he continued in office under Earl Russell, carrying measures for stamping out the cattle plague, for amending the Parliamentary Oaths Act, and for suspending the Habeas Corpus Act in Ireland at the time of the Fenian activity. On the defeat of the Russell-Gladstone ministry in 1866 upon the reform question, Grey's official career closed; but he continued to sit in parliament until 1874, when he finally retired from public life. He died at his seat of Falloden, near Alnwick, September 9, 1882.—His grandson and successor, SIR EDWARD GREY (born 1862), studied at Oxford, became Radical M.P. for part of Northumberland in 1885, and in 1892–95 was Foreign Under-Secretary.

Grey, SIR GEORGE, K.C.B., governor and commander-in-chief of New Zealand, was born at Lisbon, in Portugal, in 1812. He was educated at the Royal Military College at Sandhurst, and on attaining his captaincy undertook in 1837 the exploration of the interior of Australia. In September 1838 he organised another expedition to explore the Swan River district. He returned to England in 1840, and published his *Journals of Two Expeditions in North-western and Western Australia*. His enterprise and ability obtained for him, unasked, in 1841, from Lord J. Russell, then Colonial Secretary, the post of governor of South Australia. In 1846 he was made governor of New Zealand. Both here and in Australia his first task was to acquire the language of the natives, with whom he became more popular than any preceding governor. His government appeared to the authorities at home to be so wise and conciliatory that in 1848 he was made K.C.B. (civil), and in 1854 was appointed governor and commander-in-chief of the Cape of Good Hope. The task of allaying the asperities and irritation left by the Kaffir war demanded high powers of statesmanship; Grey was, however, equal to the occasion. Industry revived, and brighter days began to dawn upon the colony. In 1858, however, the Colonial Office interfered with measures which he considered necessary, and he threw up his post and came to England. Public opinion at the Cape was so strongly manifested in his favour that he was requested by the government to resume his governorship. On the breaking out of the Indian mutiny Grey sent every soldier he could spare to the assistance of the Indian government, and received the acknowledgments of the British government and parliament for his promptitude and energy. In 1861 he was again appointed governor of New Zealand, in the hope that he would bring the war then raging in the colony to a satisfactory conclusion. The natives received him with joy and veneration, and he succeeded in bringing about pacific relations with the Maoris. He resigned his office and came to England in 1867, but afterwards returned to the colonies. Grey accepted the office of Superintendent of Auckland in 1875, with a seat in the Legislature, and he strongly but fruitlessly opposed the Abolition of the Provinces Act. After its passing his office of superintendent ceased; but in 1877 he became premier of New Zealand, and carried various acts of great practical utility. Grey had almost unbounded influence with the Maori chiefs, which he used in cultivating friendly relations between the natives and the white population. He resigned in 1884, but lived till 19th September 1898. He published *Journals of Discovery in Australia* (1841), *Polynesian Mythology* (1855), and *Proverbial Sayings of the Ancestors of the New Zealand Race* (1858). See Lives by Rees (3d ed. 1893) and Milne (1899).

Grey, LADY JANE, the 'nine days' queen,' was born at Bradgate, Leicestershire, in October 1537. She was the eldest daughter of Henry Grey, Marquis of Dorset, who in 1551 became Duke of Suffolk, and of Lady Frances Brandon. The latter was the daughter of Charles Brandon, Duke of Suffolk, by Mary, younger sister of Henry VIII., and widow of Louis XII. of France. Lady Jane was brought up rigorously by her parents, every petty fault punished with 'pinches, nips, and bobs;' but Aylmer (q.v.), her tutor, afterwards Bishop of London, endeared himself to her by his gentleness, and under him she made extraordinary progress, especially in languages—Latin, Greek, French, Italian, and Hebrew. Roger Ascham tells how in December 1550 he found her reading Plato's *Phædo* in the original, while the rest of the family were hunting. She also sang and played well, and was versed in other feminine accomplishments. In 1553, after Somerset's fall, the Duke of Northumberland, foreseeing the speedy death of the boy-king Edward VI., determined to change the succession and secure it to his own family. Lady Jane, not sixteen years old, was therefore married, strongly against her wish, to Lord Guildford Dudley, Northumberland's fourth son, on 21st May 1553; and on 9th July, three days after Edward's death, the council informed her that his 'plan' had named her as his successor. On the 19th, the brief usurpation over, she found herself a prisoner in the Tower; and four months later, pleading guilty of high-treason, she was sentenced to death. She spurned the idea of forsaking Protestantism for love of life, and bitterly condemned Northumberland's recantation: 'Woe worth him! he hath brought me and our stock in most miserable calamity by his exceeding ambition.' Queen Mary might have been merciful; but Suffolk's participation in Wyatt's rebellion sealed the doom of his daughter, who on 12th February 1554 was beheaded on Tower Hill. She was 'nothing at all abashed, neither with fear of her own death, which then approached, neither with the sight of the dead carcass of her husband, when it was brought into the chapel—a sight to her no less than death.' From the scaffold she made a speech: 'The fact, indeed, against the queen's highness was unlawful, and the consenting thereto by me; but touching the procurement and desire thereof by me or on my behalf, I do wash my hands thereof in innocency. . . . I die a true Christian woman.' With Lord Guildford she is buried in the Tower church of St Peter ad Vincula. See the articles EDWARD VI. and MARY; also *The Chronicle of Queen Jane*, edited by J. G. Nichols for the Camden Society (1850).

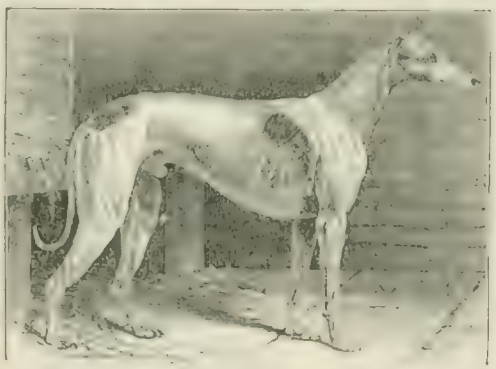
Greybeard.

Greybeards are big-bellied, narrow-necked stoneware jugs or bottles, made in Flanders about the beginning of the 17th century, and so called from generally having a grotesque head, with a large, square-cut beard, modelled on the short neck. The face was a Protestant burlesque of Cardinal Bellarmine's.

Grey Friars. See FRIAR, FRANCISCAN.

Greyhound, a breed of great antiquity, the only breed of dog which has retained its original

shape; many Egyptian monuments are decorated with figures of dogs closely resembling the smooth English greyhound. The greyhound has been known in England since the time of King Canute, who confined its use to the nobility by statute. Until comparatively modern times only land owners were permitted to use the greyhound. When the game-laws were relaxed, coursing became open to all, until now upwards of five thousand greyhounds are kept for public Coursing (q.v.). Clubs were formed for the encouragement of the sport, and a scale of points by which competing greyhounds could be tested was arranged. When it is desired to test two rival greyhounds, they are placed in the hands of the 'slipper,' towards whom the hares are driven. After getting the dogs in a straight line behind the hare, he liberates them by means of a mechanical contrivance, allowing the hare from 50 to 80 yards start. The 'judge,' who follows on horseback, then notes the points scored by either greyhound, giving his decision, from which there is no appeal, at the end of each course. The scale of points adopted is as follows: 'the run-up,' first reaching the hare, one to three points, according to lead gained; 'the turn,' causing the hare to turn at an acute angle, two points; 'the wrench,' turning at an obtuse angle, one point; 'the go-by,' starting behind a competitor and passing him, two points; 'the trip,' knocking the hare over but not killing, one point; 'the kill,' not more than two points, sometimes none, according to merit. Many greyhounds, after they have been repeatedly coursed, 'run cunning' or 'lurch'—i.e. allow their opponent to do all the work, only waiting for an opportunity to kill; this vice is hereditary, and must be guarded against in breeding. The greyhound is a large and graceful dog, conveying an impression of great speed. His



Greyhound.

head should be long and narrow, with powerful jaws; shoulders, sloping back, allowing free play for the fore-legs; fore-legs, strong and muscular; chest, deep and narrow; hind-legs, very long from hip to hock, and 'well-bent.' The points of the greyhound are neatly summed up in the 15th century rhyme:

> The head of a snake,
> The neck of a drake,
> A back like a beam,
> A tail like a stream,
> The foot of a cat,
> And the tail of a rat,

which is still a fairly accurate description. The greyhound is rarely kept as a companion, its intelligence not being of a high order. The Russian and Circassian greyhounds are identical in shape with the English greyhound, but much rougher in coat, and slower. The Italian and Turkish greyhounds are shaped very much the same way, but on a very reduced scale; they are used entirely as pets, being too delicate for any active work. See H. Dalziel, *The Greyhound: its History, Points, and Breeding* (1886).

Greymouth, a rising port of New Zealand, on the west coast of South Island, at the mouth of the Grey River, 190 miles SSW. of Nelson. Extensive harbour-works, including two breakwaters and the addition of 600 feet of wharf, have been erected since 1885, and railways to Nelson and Christchurch were commenced in 1887. The entire district is auriferous, and 55,036 ounces of gold (value £220,503) were exported during 1887–88. Greymouth, however, is famous chiefly for its coal, of which over 130,000 tons, of the best quality in Australasia, were raised in 1887 in the neighbourhood. Pop. (1891) 3787.

Greystone, a rock-term (now disused) for certain light gray lavas intermediate in character between trachytic and basaltic lavas. The greystones are probably all varieties of Trachyte (q.v.), but perhaps to some extent of liparite and even of basalt.

Greytown (*San Juan del Norte*), the only Nicaraguan port on the Caribbean Sea, is on the northern delta of the San Juan River, which until 1889 was nearly choked with sand. In that year labourers were despatched from the United States to commence work on the interoceanic canal, of which Greytown is the proposed terminus on the Atlantic side, and to construct a breakwater here. Greytown was neutralised under the Clayton-Bulwer treaty, and has been a free port of Nicaragua since 1860. Pop. 1500.

Greywacke (Ger. *Grauwacke*), a partially translated German word, used as the name of an indurated sedimentary rock, which occurs extensively among the Palæozoic systems, where it is associated with similarly indurated shales and conglomerates. It is an aggregate of rounded subangular and angular grains and splinters of quartz, felspar, and slate, sometimes with mica and grains of other minerals and rocks, embedded in a hard paste or matrix, which may consist of siliceous, calcareous, argillaceous, or felspathic matter. The rock is generally harder than most sandstones, and is usually gray or dark blue in colour, but green, red, brown, yellow, and even black varieties are met with. It varies in texture from fine-grained and compact up to conglomeratic and brecciiform, and occurs in thick massive beds like liver-rock (see SANDSTONE), and in thinner beds and layers like ordinary sandstones and flagstones. It represents the muddy sediments of the Palæozoic seas, and often retains ripple-marks, sun-cracks, worm burrows and castings, and other superficial markings.

Greywethers, the name given to large blocks of hard sandstone, which are scattered sporadically over the southern and south-eastern parts of England. The name has probably been suggested by their resemblance in the landscape to sheep lying about. Other names by which they are known are *Sarsden Stones*, *Druid Stones*. They are as a rule roughly oblong, and are of all sizes up to 10 or 15 feet in length, and 2 or 4 feet in thickness; and are believed to be the relics of beds of Eocene age which formerly extended over all the region where they occur. These beds probably consisted chiefly of loose sand, &c., the greywethers representing concretionary portions hardened by siliceous cement, which have thus withstood the denudation that has swept away the incoherent deposits of which they once formed a part. The outer ring of monoliths at Stonehenge is formed of greywethers.

Grieg, Edvard, a Norwegian composer, born at Bergen, 15th June 1843. He was of Scotch descent, his ancestors, Greigs, having emigrated from Fraserburgh during the Jacobite troubles. Grieg received instruction in music from his mother, till at the age of fifteen, on the recommendation of Ole Bull, he was sent to the Conservatorium at Leipzig. Thence, in 1863, after a severe illness, he went to Copenhagen, and afterwards to Christiania, where he was settled as a teacher for about eight years, and enjoyed the intimate friendship of Björnson and Ibsen. He visited Liszt in Rome in 1869. For a while a wanderer, he occupied for some years a romantic hut on the Hardangerfjord, and subsequently settled near Bergen. The Norwegian parliament conferred a pension on him to enable him to devote himself to composition. His works are mainly for the pianoforte, and in small forms, but embrace a sonata and a concerto for pianoforte, three violin and pianoforte sonatas, numerous songs, and a few orchestral and small choral pieces. Beyond that of any other composer, his music is characterised by the strongest national peculiarities, extreme gloom and brilliance alternating like the Norwegian summer and winter; its merriment is often wildly elfish in its freaks, and its pathos sometimes has a ghostly weirdness. He is as far removed from the commonplace as Chopin. He is of course immensely popular with his countrymen, and the great and growing favour with which he is regarded in England was strongly expressed on his visits in 1888, 1889, and 1897.

Grierson, Sir Robert, of Lag, persecutor of the Covenanters, was born about 1655, and succeeded his cousin in the family estates in 1669. He acted for some years as steward of Kirkcudbright, and carried out the infamous work of harrying the peasantry with such zest and vigour as to leave his name after two hundred years a byword in Galloway for ferocious cruelty. And his brutal speech to Kenmure about a martyr's body which he had denied the decency of burial: 'Take him, if you will, and salt him in your beef-barrel,' shows the popular tradition to be in harmony with fact. He was brother-in-law to the Duke of Queensberry, and through his influence was made a Nova Scotia baronet in 1685, and awarded a pension of £200. He was one of the judges of the Wigtown martyrs, and his name survives in infamy upon their tombstone. After the Revolution he was heavily fined and imprisoned for his obstinate opposition, and later was charged with coining false money when experiments in stamping linen alone were in question! He died 31st December 1733. A rough but really vigorous piece of verse, *Lag's Elegy*, was current in Dumfriesshire soon after his time, and was admired in the next century by Carlyle. The popular imagination wove many a gloomy and awful fancy around Lag's memory, and all the most effective of these Scott worked with marvellous art into 'Wandering Willie's Tale'—a magnificent phantasy of genius. Old Redgauntlet, with the horseshoe frown upon his brow, and his pre-eminence among the damned in hell, is but a creative realisation of the Laird of Lag traditional in Galloway. See Colonel Fergusson's book, *The Laird of Lag: a Life Sketch* (1886).

Griesbach, Johann Jakob, author of the first critical edition of the New Testament, was born at Butzbach, in Hesse-Darmstadt, January 4, 1745. He studied theology at Tübingen; at Halle, where Semler influenced his whole after-life; and at Leipzig, where he became acquainted with Ernesti. He commenced lecturing as *privat-docent* in Halle, and in 1773 was made extra-ordinary professor; but in 1776 he was called as ordinary professor to Jena, where he continued to teach with great success till his death on 24th March 1812. The great work with which his name is associated is his critical revision of the New Testament text. Amongst his notable works are the *Synopsis Evangeliorum* (2 vols. 1774–75; 3d ed. 1809); his edition of the whole New Testament (1775; new ed. 1796–1806); *Populäre Dogmatik* (1779; 4th ed. 1789); *Commentarius Criticus in Textum N. Test.* (1798–1811); and the *Opuscula Academica* (1825). The grand feature of Griesbach's critical system is his threefold division or classification of the New Testament MSS.: (1) The Alexandrine recension; (2) the Latin or Western recension; (3) the Byzantine or Eastern recension. See Bible; and the Lives by Köthe (1812), Augusti (1812), and Eichstädt (1815).

Griffin (Lat. *gryphus*; Gr. *gryps*), a chimerical creature, first mentioned by Aristeas about 500 B.C. The griffin is variously described and represented, but the shape in which it most frequently appears is that of a cross between a lion and an eagle, having the body and legs of the former, with the beak and wings of the latter, and the addition of pointed ears. Sometimes the four legs are all like those of an eagle, and the head is that of a cock. The figure seems to have originated in the East, as it is found in ancient Persian sculptures. Amongst the Greeks it appears on antique coins, and as an ornament in classical architecture. Griffins abound in the legendary tales of the Teutonic nations, and the name (Ger. *greif*, Dan. *grif*, &c.) has passed into most Teutonic dialects. In the bestiaries of the middle ages the appearance and habits of the griffin were discussed with much particularity; it was the emblem of vigilance, and was understood to guard hidden treasures in Bactria; and the griffin (or gryphon) is still familiarly known to heraldry. As such it appears in the arms of the city of London, griffins being the supporters; and on the removal of Temple Bar a sculptured griffin was erected on the site (November 1880). For the Griffin Vulture, see Vulture.—Griffin is a name jocularly given in India to a newcomer from England, a greenhorn.

Griffin (Heraldry).

Griffin, Gerald, novelist, was born at Limerick, 12th December 1803, and early began to write for the papers and magazines. He came to London in 1823, resolved to 'revolutionise the dramatic taste.' Of course he failed to get his tragedies acted, but he was more successful with novels—*Holland Tide* (1827), *Tales of the Munster Festivals* (1827), and *The Collegians* (1828), on which the drama of the *Colleen Bawn* is founded. These were followed by some dozen more novels and many minor tales. Griffin joined the Society of Christian Brothers, and died in the North Monastery, Cork, 12th June 1840.

Griffith's Valuation, the main authority for the adjustment of rents under the Irish Land Act, was calculated by Mr (afterwards Sir) Richard Griffith, appointed commissioner to carry out the scheme resolved on by the government in 1825. The results were first published in 1850, and have been much discussed in recent years; but the valuation may be regarded as a most minute and exact basis for equitable taxation and the fixing of fair rents.

Grig, or Glut (*Anguilla latirostris*), a widely distributed species of eel, found on British and European, Chinese, West Indian, and other coasts. See Eel.

Grigoriopol, a town of Kherson, South Russia, on the left bank of the Dniester, 82 miles NW. of

Odessa. Its 7918 inhabitants cultivate tobacco, wine, and fruit, and manufacture leather.

Grille, a lattice, or grating, or screen, or open work of metal, sometimes also of wood, generally used to enclose or protect a window, or some shrine, or tomb, or sacred spot. A grille should be all hammered and punched, without filing. The small screen of crossed iron bars inserted in the door of a monastery or prison, for holding conversation and reconnoitring through, is also called a grille.

Grillparzer, FRANZ, an Austrian dramatic poet, for some time popularly regarded as the greatest poet of his nation, was born at Vienna, 15th January 1791, and laboured in the imperial civil service from 1813 to 1856. He died 21st January 1872 at Vienna. Grillparzer first attracted notice in 1816 by a 'fate' tragedy, *Die Ahnfrau*. His next tragedies, *Sappho* (1819) and *Das goldene Vlies* (1821), the latter a trilogy, are beautiful pieces of work, modern in sentiment, classic in style. And the same features, with that of lyric force added, characterise the dramas *Des Meeres und der Liebe Wellen* (1840) and *Der Traum ein Leben* (1840). Besides these he wrote the historical plays *König Ottokar's Glück und Ende* (1825) and *Ein treuer Diener seines Herrn* (1830), with others. In lyric poetry he likewise produced a good deal of meritorious work; and he wrote one good prose novel, *Der Spielmann*. A collected edition of his works, including an autobiography, was published in 10 vols. at Stuttgart in 1872, and another of 16 vols. in 1889. See Lives by Faulhammer (1883) and Laube (1884), and works by Volkelt (1889) and A. Farinelli (1895).

Grilse. See SALMON.

Grimaldi. See MONACO.

Grimaldi, JOSEPH, the typical representative of 'the genuine droll, the grimacing, filching, irresistible clown' of the English pantomime, was born in London on 18th December 1779, the year in which Garrick died. He first appeared on the boards of Drury Lane when one month short of two years old, and in his third year he had his first engagement at Sadler's Wells Theatre, where he regularly performed (except for one season) down to the date of his retirement from the stage, prematurely worn out by sheer hard work, in 1828. He used regularly for some months every year to perform nightly at two theatres, and once he achieved the feat of acting at three different theatres on the same night. He died in London, 31st May 1837. See *Memoirs of Joseph Grimaldi*, edited by Charles Dickens (1838).

Grime's Dyke. See ANTONINES' WALL.

Grimm, FRIEDRICH MELCHIOR, BARON, a clever German critic, who knew every one worth knowing at Paris in the later half of the 18th century. He was born at Ratisbon, 25th December 1723, and after completing his studies at Leipzig, and making an egregious failure with a tragedy, accompanied the young Count de Schönberg to Paris, and soon after became reader to the Crown-prince of Saxe-Gotha. He was still in very straitened circumstances when he became acquainted with Rousseau in 1749, and was by him introduced to Diderot, Baron Holbach, and Madame d'Epinay. The intimacy of his relations with this lady cost him later the friendship of the jealous Rousseau. Grimm quickly became a general favourite, and his connection with the Encyclopédistes, added to his own multifarious acquirements and versatility of mind, opened up to him a brilliant career. He became secretary to Count Friesen, next to the Duke of Orleans, and now began to write for several German princes those famous literary bulletins which cover about forty years, and contain the most trenchant criticism of all the most important of current French books. In 1776 he was raised by the Duke of Gotha to the rank of baron, and appointed minister-plenipotentiary at the French court. On the breaking out of the Revolution, he withdrew to Gotha, and afterwards to the court of Catharine II. at St Petersburg whence he was sent in 1795 as minister of Russia to Hamburg. He died at Gotha, 19th December 1807. His *Correspondance Littéraire, Philosophique et Critique*, extending from 1753 to 1790, was published in three divisions (16 vols. 1812-13); a supplementary volume in 1814. Later editions are those by Taschereau (15 vols. 1829-31), and Tourneux (16 vols. 1878-82). The *Correspondance inédite de Grimm et Diderot* was published in 1829. See Sainte-Beuve, *Études sur Grimm* (1854); and Edmond Scherer's *Melchior Grimm* (Paris, 1887).

Grimm, JAKOB LUDWIG KARL, the founder of scientific German philology, and one of the noblest of ancient or modern scholars, was born January 4, 1785, at Hanau, in Hesse-Cassel. He studied law at Marburg, and learnt scientific method from Savigny, at whose invitation he spent the greater part of the year 1805 in study at Paris. On his return he was appointed to a clerkship in the war-office, and in 1808, private librarian to Jerome Bonaparte, king of Westphalia, who also made him auditor to the council of state. His brother Wilhelm had also by this time settled at Cassel. The first fruit of his studies was the treatise *Ueber den Altdeutschen Meistersang* (1811), which was followed in 1812 by the first volume of the famous *Kinder- und Hausmärchen*, collected by the two brothers—a work which has carried their name over the civilised world in the happiest and most enduring kind of immortality, and has formed a foundation for the new science of comparative Folklore (q.v.). Nor has a contribution to storiology since been made equal in importance to the earliest. The second volume followed in 1814; the third, containing the notes, in 1822. In 1813 Grimm was secretary to the ambassador of the Elector of Hesse, whom he attended at Paris, and at the Congress of Vienna. In 1815 he was sent to Paris to claim the books carried off by the French. His brother Wilhelm had already received a post in the Cassel library, and in 1816 Jakob became second librarian under Völkel, on whose death in 1828, the two brothers being disappointed of the first and second places in the library, removed to Göttingen, where Jakob became professor and librarian, and Wilhelm under-librarian. Here for seven years he studied the language, ancient laws, history, and literature of Germany, but never made an effective lecturer. He was one of the famous seven professors who protested in 1837 against the abolition of the constitution by the king of Hanover, for which act he was dismissed, together with his brotker, and obliged to retire to Cassel. In 1840 they were both invited to Berlin, where they received professorships, and were elected members of the Academy of Sciences. Here Jakob continued his studies with the most single-minded devotion, producing a series of works still unsurpassed for their stupendous erudition. Working up to the last with a devotion undivided by wife or children, he died 20th September 1863.

His *Deutsche Grammatik* (1819; 2d ed. entirely recast, Gött. 1822-40) is perhaps the greatest philological work of the age, and may be said to have laid the foundation of the *historical* investigation of language. It traces the German language historically through all its dialects. His *Deutsche Rechts-Alterthümer* (1828; 2d ed. 1854) and *Deutsche Mythologie* (1835; 3d ed. 1854; 4th ed. by Meyer, 1875-78; Eng. trans. by J. S. Stallybrass, 4 vols. 1879-88) are works of exhaustive

erudition upon the society of the middle ages in central Europe, and the religious traditions and superstitions of the Teutonic races from the earliest times. Only less important is his *Geschichte der Deutschen Sprache* (1848; 3d ed. 1868), and his *Reinhart Fuchs* (1834). In company with his brother Wilhelm he published many editions of old German classics, *Deutsche Sagen* (1816-18; 2d ed. 1865-66); and projected and commenced the great and still unfinished *Deutsches Wörterbuch* (vol. i. 1854; three-fourths finished by 1897, with the collaboration of Heyne, Hildebrand, Lexer, and Weigand). The first volume of Grimm's *Kleinere Schriften* (8 vols. 1867-86) contains an autobiography which reveals a character entirely free from jealousy or envy, full of warm human sympathy, and combining in an almost unexampled degree a noble simplicity of life with lofty elevation of purpose. Many collections of his letters have been printed. See the studies by Scherer (2d ed. 1884), Berndt (1884), and those devoted to the two brothers by A. Duncker (1884) and Schönbach (1885).

Grimm's Law is the name given to the rule which regulates the *Lautverschiebung*, or permutation of certain primitive consonants, which takes place in the Teutonic languages. The law, as finally formulated by Jakob Grimm, is that if the same roots or words exist in Sanskrit, Greek, and generally in Latin, Celtic, Lettic, and Slavonic, and also in Gothic, English, Dutch, and other Low German dialects on the one hand, and in Old High German on the other, the following correspondences are to be expected: (1) Gothic has a soft mute, and High German a hard mute, in place of the corresponding aspirate in Sanskrit and Greek; (2) Gothic has a hard mute, and High German an aspirate, in place of the corresponding soft mute in Sanskrit and Greek; (3) Gothic has an aspirate, and High German a soft mute, in place of the corresponding hard mute in Sanskrit and Greek. Thus, a primitive *th* becomes *d* in Low German, and *t* in High German, as in the words *th*ugatēr, *d*aughter, *t*ochter. A primitive *d* becomes *t* in Low German, and *z* in High German, as in *d*uo, *t*wo, zwei; or *d*ens, *t*ooth, zahn; or *d*ecem, *t*en, zehn. A primitive *t* becomes *th* in Low German, and *d* in High German, as in *t*res, *th*ree, *d*rei; or *t*u, *th*ou, *d*u; or *t*enuis, *th*in, *d*ünn. Similar changes affect the labials and gutturals, as in *p*ecus, *f*ee, vieh; *p*ater, *f*ather, vater; *f*agus, *b*eech, *p*uoche; and in *o*culus, *e*ye ('eye'), auge; *qu*is, *wh*o, wer; or *ch*ortos, *g*arden, *h*orto. The normal changes are set forth in the following table:

	Labials.			Dentals.			Gutturals.		
Greek, &c.	p	b	ph	t	d	th	k	g	kh
Gothic, &c.	f	p	b	th	t	d	(h)	k	g
Old High German.	b(v)	f	p	d	z	t	g(h)	ch	k

The credit of the discovery of the *Lautverschiebung* is not wholly due to Jakob Grimm. Thre and Rask had discovered, as early as 1818, the law of the transmutation of consonants in Greek and Gothic, while Grimm, in the second edition of his *Deutsche Grammatik*, which appeared in 1822, added the corresponding changes in Old High German, and formulated the Law as it now stands.

Grimm's Law may be interfered with by the action of other laws, especially by the position of the accent, as formulated in Verner's Law (q.v.). Thus *frāter* is accented on the first syllable and *patēr* on the second, consequently, though we have *brother* and *father* in English, we find *bruder* and *vater* in High German. The accent in *patēr* has interfered with the regular action of the *Lautverschiebung*, and prevented the normal change of *t* to *d* from taking place.

Thus Grimm's Law may be defined as the statement of certain phonetic facts which happen invariably unless they are interfered with by other facts. The great use of Grimm's Law, in addition to the identification of words in different languages, is in the detection of loan words. Any etymology which violates Grimm's Law, as qualified by other phonetic laws, must be rejected unless it can be explained as a loan word.

The causes which brought about the changes formulated in Grimm's Law are obscure. They are probably due to the settlement of Low German conquerors in central and southern Germany.

See Douse's *Grimm's Law: a Study of Lautverschiebung* (1876); Max Müller's *Lectures on the Study of Language*, 2d series, lecture v. (1864); Morris' *Historical Outlines of English Accidence*, chap. ii. (1872).

Grimm, Wilhelm Karl, brother of the preceding, was born at Hanau, February 24, 1786. Great part of his life has already been told in that of his brother. He was his companion in study at the Lyceum of Cassel, the university of Marburg, and again at Göttingen, where in 1830 he was appointed under-librarian and supernumerary professor of Philosophy. He joined his brother in the protest against the king of Hanover, shared his exile, and also his call to Berlin. There they laboured together, and were commonly known as the Brothers Grimm. Under that name also they have a certain immortality in the affections of the children of the civilised world. Wilhelm died 16th December 1859. His earliest independent work was a German translation of the Danish *Kompe-Viser* (1811-13). He edited many old German texts, and collaborated with his brother Jakob in several of his works. His own most important book is *Die deutsche Heldensage* (1829; 2d ed. 1867). His *Kleinere Schriften*, ed. by Hinrichs, fill 4 vols. (1881-86), and contain an autobiography.

Grimma, a town of Saxony, on the Mulde, 19 miles SE. of Leipzig by rail. It has a town-hall (1442), a former royal castle (now a court-house), a celebrated school (1550, the 'Moldanum Illustre'), and 8992 inhabitants, who support themselves by manufactures and agriculture. See Bora, K. von.

Grimmelshausen, Johann Jacob Christof von, a German novelist of the 17th century. There is some uncertainty as to the date and place of his birth, but in all probability he was born at Gelnhausen in Hesse-Cassel about the year 1625. In early boyhood he was carried off by a troop of soldiers, and became a soldier himself, serving on the imperial side in the Thirty Years' War up to its close. For several years after the end of the war he seems to have led a wandering life, but ultimately settled down at Renchen, near Kehl, where he held the post of bailiff for the Bishop of Strasburg, and passed the remainder of his days in peace and prosperity, dying Amtmann of the town in 1676. In the leisure of his later life he produced a series of remarkable novels, all the more remarkable for appearing in the sterile period that succeeded the Thirty Years' War. His first attempt was an imitation of Cyrano de Bergerac, or perhaps of Godwin's *Voyage of Domingo Gonsales to the Moon*, but his best works are on the model of the Spanish picaro, or rogue and vagabond romances, and deal with the abundant materials furnished by his own life. The form was all that he borrowed; the rich humour, dramatic power, and local colour of his tales are all his own. The sufferings of the German peasantry at the hands of the lawless troopers who overran the country have never been more powerfully pictured than in the opening chapters of *Simplicissimus* (first printed in 1669), which is evidently autobiographical to a great extent. It was followed in 1670 by *Trutz Simplex*, the story of an adventuress of the same sort as the *Picara Justina* of Andres Perez, and *Springinsfeld*, the history of a soldier of fortune, which was

succeeded in 1672 by the *Wonderful Bird's nest*, a fanciful production somewhat like Guevara's *Dial of Princes*. Besides these Grimmelshausen wrote the *Ewig währender Calender*, and three or four other tales or tracts. His writings, especially *Simplicissimus*, seem to have been very popular in his own time, but to have fallen into neglect in the last century. Their merits, however, have been recognised of late years, and the best of them have been reprinted with introductions and notes, e.g. in the edition of Von Keller (4 vols. Stutt. 1854–62), that of Heinrich Kurz (4 vols. Leip. 1863), and of Julius Tittman (4 vols. Leip. 1874–77).

Grimoire (whence the English *grammar*, 'magic'), the French term for the book of formulas which sorcerers used for invoking demons; hence also gibberish. The older forms of the word (*gramaire*, *gramaire*) approximate to the Low Latin *gramma*, 'a letter;' the origin of the word being obvious.

Grimsby, or GREAT GRIMSBY, a parliamentary, municipal, and county borough and seaport of Lincolnshire, is situated on the right bank of the Humber, 20 miles ESE. of Hull and 41 NE. of Lincoln. It consists of two portions: the older, comprising a number of streets irregularly laid out, is at the head of the harbour; and the newer part, called the 'Marsh,' extending along the east side of the harbour, is regular and spacious. The parish church, a good cruciform edifice in the Early English style, was restored in 1859. A statue of the Prince Consort was unveiled in 1879, and a public park of 27 acres opened in 1883. In the time of Edward III. Grimsby was a port of considerable importance, which, however, it gradually lost as its harbour became silted up. The town is famous as the largest fishing port in the kingdom, its trawlers and smacks being mostly engaged in the cod, herring, and whelk fisheries. Its importance as a place for the landing of fish dates from 1849–58, when docks began to be constructed under the auspices of the Manchester, Sheffield, and Lincolnshire Railway, which carries the fish to the principal industrial centres of the northern Midlands. The docks cover altogether an area of about 350 acres. The industries of the place include shipbuilding, tanning, brewing, cordage-making, and flax-dressing. About 3500 vessels, with an average burden of 675,000 tons, enter every year, and the number and burden of those clearing annually are about the same. The imports of the port reach the annual value of 4½ millions sterling, and the exports 7¾ millions. Grimsby since 1832 has returned only one member to parliament. Pop. (1851) 12,263; (1871) 28,503; (1891) 58,603, of whom 51,876 were within the municipal boundary. See works by Oliver (1825) and Davenport (1866).

Grindal, EDMUND, Archbishop of Canterbury, was born near St Bees in 1519, and educated at Cambridge, where he was in turn scholar, fellow, and master of Pembroke Hall. Already a prebendary of Westminster under Edward VI., he lived abroad during Mary's reign, and there imbibed the spirit of Geneva, returning to England on the accession of Elizabeth. On Bonner's deprivation in 1559 he was made Bishop of London, in 1570 Archbishop of York, and in 1575 he succeeded Parker in the see of Canterbury. His Puritanistic sympathies soon estranged him from the court, and his resolute refusal to put down against his own conscience 'prophesyings' or private meetings of the clergy for mutual help in the interpretation of Scripture, led to his being sequestered from his functions by the imperious queen in 1577. Not for five years was he restored, and a year later he died at Croydon, July 6, 1583. 'Being really blind,' says Fuller, 'more with grief than age, he was willing to put off his clothes before he went to bed, and in his lifetime to resign his place to Doctor Whitgift, who refused such acceptance thereof. And the queen, commiserating his condition, was graciously pleased to say that, as she had made him, so he should die an archbishop.' His few writings, with a Life by the Rev. William Nicholson, were printed by the Parker Society in 1853.

Grindelwald, one of the most beautiful valleys (3468 feet) of the Bernese Oberland in Switzerland, about 12½ miles long and 4 broad, forms the approach to the two Grindelwald glaciers. The chief hotel and part of the village (pop. 3089) were destroyed by fire on 18th August 1892.

Grinding. See CUTLERY.

Gringore, or GRINGOIRE, PIERRE, a favourite French poet under Louis XII. and Francis I., was born, perhaps at Caen, between 1475 and 1480, and early became known as a writer of moral and allegorical poems, next of satirical farces abounding in allusions to the social and political circumstances of the time. For the first twenty years of the 16th century he played the most important rôles in the theatrical society of 'Enfants sans Souci,' first as Mère Sotte, next as Prince des Sots; and as such was active in the production and representation of pantomimic satirical farces. He is an important figure in literary history as one of the creators of the French political comedy. He abused the enemies of Louis XII., and thus found cover for his freedoms against the vices of the nobility, the clergy, and even the sacred person of the pope himself. In later life he entered the service of the Duke of Lorraine as a herald, and confined his muse to religious poetry alone. He died in 1544. The most important among his pieces are *Le Jeu du Prince des Sots* (1511), directed especially against Pope Julius II.; *Les folles Entreprises*, a series of half allegorical monologues aimed at the chief existing grievances in church and state; *Les Entreprises de Venise*, and *La Chasse du Cerf des Cerfs*, both political, the title even of the latter being but a dimly-veiled allusion to Pope Julius (*Servus servorum Dei*); and the famous *Mystère de Monseigneur Saint Loys*, written about 1524. Gringore's works have been edited by Héricault, Montaiglon, and Rothschild (4 vols. 1858–77). He is the chief figure in a comedy of Banville's, but his description in Hugo's *Notre Dame* must not be taken as historical. See Picot, *Pierre Gringoire* (Paris, 1878), and another work by Badel (Nancy, 1893).

Grinnell Land, a barren, mountainous Polar tract on the west side of Kennedy Channel (the northern continuation of Smith's Sound), which separates it from Greenland. It was discovered by Dr Hayes of Kane's expedition in 1854, and named after Henry Grinnell (1800–74), of New York, who had fitted out the expedition. Greely in 1882 thoroughly explored it. North and south it is covered with ice-caps; between them lie valleys that get quit of their snow in summer, and support herds of musk oxen and the usual Arctic fauna. In the interior he discovered Lake Hazen, 60 miles long, and two ranges of mountains, one containing a peak (Mount Arthur) 5000 feet high.—Another Grinnell Land, discovered by De Haven in 1850, lies further to the south-west, off the north-west extremity of North Devon Island.

Grinstead, EAST, an old-fashioned town of Sussex, 36 miles S. by E. of London by rail, which till 1832 returned two members to parliament. Here is Sackville College, of which Dr Neale was warden, and the convent of the sisterhood of St Margaret, with Home and Orphanage. Pop. 5390. —WEST GRINSTEAD is 18 miles to the south-west.

Griping, or GRIPES, a popular name for all painful affections of the bowels, whether attended with Constipation (q.v.) or Diarrhœa (q.v.). When pains of this kind are spasmodic, they are termed Colic (q.v.). The action of purgative medicine is often attended by more or less of griping pain, which may be averted in certain cases by the careful choice of the medicine, or by combination of it with Carminatives (q.v.), or with a little opium.

Griqualand West and **East** are two British districts of South Africa, one a part of Cape Colony (q.v.), the other a dependency of it, and named from the Griquas or Bastaards, who are a mixed race sprung from Dutch settlers and native women.—*Griqualand West* lies to the north-east of Cape Colony, is bounded on the S. by the Orange River, on the N. by Bechuana territory, on the E. by Orange Free State, on the W. by the Kalahari country. Portions of the country are suitable for sheep-farming and agriculture, but the chief source of wealth is the diamond-fields. The first diamond was discovered in 1867, and from that time a steady stream of immigration set in; settlements were formed, all nationalities being represented, and digging was vigorously prosecuted. Diamonds to the value of above £12,000,000 were found there between 1871 and 1880, and of about £15,000,000 between 1883 and 1887. The territory of the diamond-fields had been secured to Waterboer, a native chief, but disputes arising as to his boundaries, Griqualand West was annexed in 1871, and incorporated with Cape Colony in 1880. Kimberley, which has had railway connection with the Cape since 1885, is the chief centre of the diamond industry, and is the seat of government. The chief towns are De Beers, Du Toit's Pan, Bultfontein, Barkly, and Griqua Town. The area of Griqualand West is 15,197 sq. m., and the pop. (1891) 83,375, of whom 29,670 were whites. *Griqualand East* is that part of No-Man's-Land which lies between the Kaffir border and southern Natal. It is allotted to the Griqua chief, Adam Kok, who had removed thither with 15,000 Griquas, and to the Basutos, who had previously migrated to that country. This territory was annexed to the Cape in 1875, and is now under colonial rule, having one chief-magistrate and nine subordinates. Chief village, Kokstadt. The area is given at 7594 sq. m.; pop. (1891) 152,618; of whites, 4150. See also TRANSKEI TERRITORY.

Griselda, or GRISELDIS, the heroine of one of the most famous medieval tales, which the genius of Boccaccio, Petrarch, and Chaucer has made a permanent literary possession of the world. She was the daughter of a poor Piedmontese peasant, and for her beauty was taken to wife by the Marquis Walter of Saluzzo. To prove her truth and humility, he put her to several cruel tests—tore both her children in succession from her, and at last commanded her to return to her humble hut, as he was about to take to himself another wife. To all her husband's harsh commands she submitted with such unquestioning submissiveness and humility as to make herself for all time 'the flour of wyfly pacience.' The marquis, overjoyed to see her complete devotedness and self-renunciation, took her again to his arms, gave her back the children she had seen carried off to death, and henceforth they lived together in uninterrupted happiness.

The first literary version of the story occurs as the last tale of Boccaccio's *Decameron*—the tenth tale of the tenth day, written doubtless about 1348. Petrarch wrote a Latin version of it, *De Obedientia et Fide uxoria mythologia*, written apparently about 1373. It is accompanied by a letter to Boccaccio, in which Petrarch says that the story had always pleased him when he heard it many years before. The stuff of the story is undoubtedly much older than Boccaccio, and certainly we soon find it widely diffused and highly popular. Reinhold Köhler enumerates as many as sixteen Volksbuch versions in German from the end of the 15th to the middle of the 17th century, all based upon Heinrich Steinhöwel's translation of Petrarch (1471). As a chap-book the story was almost as common in France in the version *Le Mirroir de Dames, ou la Patience de Griseldis, &c.*, to be found in Ch. Nisard's *Histoire de Livres Populaires* (2d ed. 1864). In England editions of such were entered on the Stationers' Registers in the years 1565 and 1568, and another of 1619 is still extant, under the title, *The ancient, true, and admirable History of Patient Grisel*, &c., reprinted for the Percy Society in 1842. Substantially the same story also appears in Danish, Russian, and Icelandic folk-tales.

The chief poetical version of the story of patient Griselda is that in Chaucer's *Clerkes Tale*, one of the noblest poems in its series, and recited by perhaps the most attractive figure in the group of pilgrims. Chaucer makes the Clerk say that he had learned the tale at Padua from the lips of Petrarch himself, and in all probability he identifies himself here with the Clerk, and speaks out his own personal experience, as he was absent in Italy on the king's business from the December of 1372 to the November of 1373. The poem is distinctly founded on Petrarch's moralised Latin version, but the poetical treatment of the story is so individual that it all comes afresh from the mind of Chaucer. We have a ballad of 'Pacyent Grissel' in Bishop Percy's *Folio MS.* (vol. iii. 1868); and we find her painted among the celebrated lovers on the walls of the temple in Lydgate's poem, *The Temple of Glass*. Indeed the beauty of the story, and its allegorical value as a lesson teaching the duty of submission to the will of God, quickly touched the popular imagination, and the patience of Griselda passed into a proverb, as we see in Shakespeare and *Hudibras*. Perrault's poem of 932 irregular rhymed verses is the chief poetic elaboration of the theme in French.

The earliest dramatic representation was an old French Mystery on the subject, composed about 1395. Of more modern plays, it is enough to mention Dekker, Chettle, and Haughton's *Pleasant Comedy of Patient Grissel* (1599; ed. by J. P. Collier for the Shakespeare Society, 1841); *El exemplo de Casadas y prueva de la Paciencia*, by Lope de Vega; Hâns Sachs' *Gedultig und gehorsam Marlygrafn Griselda* (1546); Goldoni's *La Griselda;* and Friedrich Halm's *Griseldis* (1834).

See Reinhold Kohler's article in Ersch and Gruber's *Encyklopedie*, and Dr Friedrich von Westenholz, *Die Griseldis-Sage in der Literaturgeschichte* (Heidelberg, 1888). Petrarch's Latin tale of *Griseldis*, with Boccaccio's tale from which it was retold, is reprinted in the Chaucer Society's *Originals and Analogues of Chaucer's Canterbury Tales*, part ii. (1875).

Grisi, GIULIA, a celebrated singer, was born at Milan in 1811, and made her first appearance in 1828, at Bologna, in Rossini's *Zelmira*. Her fame spread rapidly over Europe; in 1832 she appeared in Paris in *Semiramis*, where the purity, melodiousness, and volume of her voice, as well as her classical beauty of features (Heine wrote of her as 'the singing flower of beauty'), secured general admiration. Bellini's *Puritani* and other operas were written for her, but Norma always remained her greatest part. London was the scene of her grandest and most successful performances; and here she married in 1836 the Marquis de Melcy, after whose death she became in 1856 the wife of the tenor, Mario, with whom she sang in America. She died in Berlin, 28th November 1869.

Gris-nez. Cape, a headland (164 feet high) in the French department of Pas-de-Calais, opposite Dover, is the point of land nearest to the English shore, the distance being barely 20 miles. About equally distant from Calais on the north-east and Boulogne on the south, the cape marks the dividing line between the North Sea and the English Channel. It has a lighthouse.

Grison (also called *Huron*), a South American weasel (*Galictis vittata*), is somewhat larger than the European weasel.

Grisons (Ger. *Graubunden*), the largest and the most thinly peopled of the Swiss cantons, is bounded E. by Tyrol and S. by Lombardy. Area, 2773 sq. m.; pop. (1888) 94,810. Nearly half are Germans; next comes the characteristic Romansch (q.v.) element (37,000), with 13,000 Italians. More than half of the whole number are Protestants. The whole canton is an assemblage of mountains intersected by narrow valleys. These last form three groups, of which the first and most important lies along the course of the Rhine, and stretches northward, occupying nearly the whole of the western portion of the canton; the second, forming the Engadine (q.v.), extends north-east along the course of the Inn; and the third comprises several smaller valleys, whose streams run southward, belonging to the basins of the Ticino and the Adige. Pastures and forests occupy a large portion of the canton; cattle and timber are the principal exports. Numerous mineral springs are found within the canton; also the health-resorts of Davos, the Upper Engadine, Seewis, &c. Iron, lead, copper, zinc, and silver occur. Within the Grisons too are several passes leading to Italy, such as the Splügen, St Bernardino, Bernina. The canton is democratic in constitution (see Switzerland). The cantonal capital is Chur or Coire (q.v.).

The country was anciently inhabited by the Rhætii, who are supposed to have been of Etruscan race (see Etruria). It was conquered by the Romans under Augustus, and added by Charlemagne to his empire in 807. During the middle ages the Bishop of Chur was the most powerful of the numerous nobles who sought to oppress the people, till they in self-defence formed themselves into leagues. One of these leagues, formed in 1424, was called the *gray* league (Ger. *der graue bund*), from the gray home-spun worn by the unionists, and hence the German and French names of the canton Graubunden and Grisons. In 1471 these separate unions entered into a general federation, which then (1497-98) formed an alliance with the Swiss cantons. See works in German by Jecklin (6 vols. Coire, 1874-86).

Griswold, Rufus Wilmot, American editor, was born in Vermont, 15th February 1815. After extensive travels at home and in Europe, he learned printing and newspaper work, next became Baptist preacher, then journalist and compiler of books in turn at Philadelphia, Boston, and New York. The most important paper which he edited during his career, the *International Magazine*, was afterwards amalgamated with *Harper's Magazine*. Griswold died in New York, 27th August 1857. His books are numerous; but, despite his industry, he was but a poor literary critic. Here the following only can be named: *Poets and Poetry of America* (1842); *Poets and Poetry of England in the 19th Century* (1845); *Prose Writers of America* 1846); *Female Poets of America* (1848); and *The Republican Court, or American Society in the Days of Washington* (1854). He was one of Poe's executors, and the Life which he furnished to the edition of his works (3 vols. 1850) has occasioned much hostile criticism.

Grit, a coarse-grained arenaceous rock. See Sandstone, Carboniferous System.

Grizzly. See Bear.

Groat Old Low German *groot*, meaning *great*), a name given in the middle ages to all thick coins, as distinguished from the 'bracteates' or thin coins of silver or gold-leaf stamped so as to be hollow on one side and raised on the other. The silver groat current in England (introduced by Edward III.) was equal to four pence. The coin—not the name—was revived (1836-56) in the modern fourpenny-piece. Groschen, the German equivalent of groats, were till 1873-76 current in the north of Germany, and equal in value to $\frac{1}{30}$th of a thaler, worth 1¼d. or 2½ cents United States currency.

Grocyn, William, the first who publicly taught Greek at Oxford, was born at Colerne, Wilts, about 1446, and educated at Winchester and New College, Oxford. He pursued his studies afterwards in Italy, acquiring a knowledge of Greek from the Greek exile Chalkondylas; and settled again in 1491 at Oxford, where Sir Thomas More was among his pupils. When Erasmus visited Oxford he lived in Grocyn's house, and he speaks of him as his 'patronus et præceptor.' In 1506 he became master of Allhallows' College, near Maidstone, and here he died in 1519.

Grodek, a town of Austrian Galicia, 20 miles SSW. of Lemberg, in the centre of a flax-growing region. Pop. 10,742, nearly one-third Jews.

Grodno, a town of Russia, on the right bank of the Niemen, 148 miles by rail NE. of Warsaw. It has a medical academy and manufactures in cloth and tobacco. The new palace, erected by Augustus III. of Poland, is a handsome edifice. At first a Russian town, Grodno fell to Lithuania in 1241. Here Stephen Bathori died in 1586; here in 1793 the Polish diet ratified the second partition of Poland; and here, too, Stanislaus Augustus, the last king of Poland, abdicated (1795). Pop. (1895) 50,500. In the neighbourhood are the mineral springs of Drusskenik.—The province of Grodno (area, 14,931 sq. m.; population, 1,556,442) is an extensive plain, largely covered with pine forests, and in parts swampy. But it is crossed by the ridge that forms the watershed between the Baltic and Black Sea basins. Its largest rivers are the Bug, Narew, and Niemen. Rye, wheat, oats, potatoes, and tobacco are grown on the fertile soil. The province is a seat of the woollen industry. Trade (in timber, grain, flax, hemp, wool, &c.) is exclusively in the hands of Jews.

Grog, spirits and cold water, without sugar. The quaint name of *grog* is said to be derived from a nickname of Admiral Vernon, who in 1745 ordered his sailors to dilute their spirits with water. He was known to his men as 'Old Grog' from his wearing grogram breeches.

Groining. See Gothic Architecture.

Grolier, Jean, a famous French bibliophile, was born in 1479 at Lyons. He was attached to the court of Francis I., went to Italy as intendant-general of the army, and was long employed in diplomacy at Milan and at Rome. After his return to France he became *Trésorier général*, and died at Paris in October 1565. It is his library that has made Grolier famous. He acquired choice copies of the best works then existing, and had them magnificently and tastefully bound, with the generous inscription, *Io. Grolierii et Amicorum.* He had no less than 3000 books, and of these about 350 have come to light, bound elegantly in brown calf, both sides ornamented with floral arabesques. The library was dispersed in 1675, and Groliers are now precious prizes to the bibliophile, their prices at auctions varying from 600 to 1200 francs. See

the study by Le Roux de Liney (1866), and Clément de Ris, *Les Amateurs d'Autrefois* (1876).

Groningen (ancient *Cruoninga*), the north-eastern province of Holland, bounded N. by the North Sea and E. by Hanover, with an area of 887 sq. m. The surface lies low; the soil is fertile, particularly in the north; in the south-east there are several marshes, though they are being rapidly drained and cultivated (as the Bourtanger). Farming and grazing are the chief pursuits of the people. Shipbuilding is extensively followed; much butter is exported, and some woollen hosiery, cloth, linen, paper, pottery, and potato-meal are manufactured. The people, 285,780 in 1894, are almost entirely of the Frisian race, and belong chiefly to the Reformed Church.

Groningen, the capital of the above province, 25 miles by rail SW. of Delfzihl, on Dollart Bay, and 34 E. of Leeuwarden. The university, founded in 1614, with new buildings of 1850, and some 360 students, possesses a library, a botanic garden, an observatory, a collection of Teutonic antiquities, a hospital, and a museum of natural history. A celebrated deaf and dumb institution was founded by Guyot in 1790. The chief industries are the manufacture of linen and woollen goods, tobacco, brushes, Dutch tiles, and boat-building. Groningen, already an important place in the 9th century, joined the Hanseatic League in 1282. From the 11th century it fought hard to maintain its independence against the bishops of Utrecht, nor did it submit until 1493, and then only to escape being handed over by the emperor to the Duke of Saxony. During the 16th century it had a very stormy history, being finally won for the United Netherlands by Maurice of Nassau in 1594. Pop. (1876) 40,165; (1893) 57,967.

Gronovius, the Latinised form of Gronov, the name of a family of scholars of German extraction, settled in Holland, the principal members of which were: John Frederic Gronovius, born at Hamburg in 1611, studied at Leipzig, Jena, and Altdorf, became in 1643 professor at Deventer, and in 1658 at Leyden, where he died in 1671. He edited Livy, Statius, Tacitus, Phædrus, Seneca, Sallust, Pliny, and Plautus, and published many works showing a profound knowledge of Roman antiquities, among them his *Observationes et Commentarius de Sestertiis.*—James Gronovius, son of the preceding, born at Deventer in 1645, studied partly there and partly at Leyden, occupied for two years a chair at Pisa, was appointed in 1679 to his father's chair, which he held till his death in 1716. His works were his *Thesaurus Antiquitatum Græcorum* (15 vols. 1697–1702), and editions of Polybius, Herodotus, Cicero, and Ammianus Marcellinus.—Abraham Gronovius, son of the preceding, born at Leyden in 1694, became librarian to the university, and died there in 1775. He showed himself worthy of the traditions of his house by his excellent editions of Justinus Pomponius Mela and Tacitus.—John Frederick, an eminent botanist, brother of the preceding, was born at Leyden in 1690, and died there in 1760. His works were *Flora Virginica* (1743) and *Flora Orientalis* (1765).—Laurence Theodore Gronovius, son of the preceding, born 1730, died at Leyden, 1778, author of *Museum ichthyologicum* (1754–56); *Zoophylacium Gronovianum* (1763–81); and *Bibliotheca regni animalis* (1760).

Groot, Gerhard (1340–84), founder of the 'Brethren of the Common Life.' See Brotherhoods.

Groote Eylandt (Dutch, 'great island'), an uninhabited island on the west side of the Gulf of Carpentaria, in North Australia. It is surrounded by reefs, and its interior is hilly. In extreme length and breadth it measures about 40 miles each way.

Gros, Antoine Jean, Baron, a French historical painter, was born at Paris on 16th March 1771, studied in the school of David, and first acquired celebrity by his picture of 'Bonaparte on the Bridge of Arcole.' His first great achievement, however, was 'Napoleon visiting the Plague-smitten at Jaffa' in 1804; and scarcely less successful were the 'Battle of Aboukir' (1806) and the 'Battle of Eylau' (1808). Gros also painted several other historical pictures illustrating the achievements of Napoleon; the 'Meeting of Charles V. and Francis I.' in 1812; in 1811–24 an immense work for the cupola of the church of Saint Geneviève; the 'Departure of Louis XVIII. for Ghent' (1815); and the 'Embarkation of the Duchess of Angoulême' (1815). In his later years he returned to the traditionary classic style of painting, and in chagrin at his want of success is believed to have committed suicide. At all events, his body was drawn out of the Seine near Meudon, 27th June 1835. Gros's paintings are marked by powerful expression and dramatic movement, but are deficient in delicacy and sentiment. See his Life by Delestre (1867) and Tripier le Franc (1878).

Grosbeak, a name applied to not a few highly-specialised finches (Fringillidæ), with thick, heavy, seed-crushing bills, 'so high that their upper contours almost form one continuous curve with that of the head.' The European Hawfinch (q.v.) (*Coccothraustes vulgaris*) and the American Evening Grosbeak (*Hesperiphona vespertina*) are good examples. But the name is applied to many other birds—e.g. to the Cardinal Grosbeaks (Cardinalis) and the Rose-breasted Grosbeak (*Habia ludoviciana*).

Groschen. See Groat.

Grose, Francis, a famous English antiquary, born at Greenford, Middlesex, in 1731, son of a rich Swiss jeweller settled in England. In the College of Heralds in 1755–63, he next became adjutant of the Hampshire and then of the Surrey militia, and, when his easy habits had brought him to the end of his fortune, began to put to profit the favourite studies of his youth and his excellent draughtmanship. His *Antiquities of England and Wales* (6 vols. 1773–87) proved a success, and in 1789 he set out on an antiquarian tour through Scotland. His splendid social qualities, his rich humour and good nature, which fitted well with his Falstaff-like bulk, made him friends everywhere. Burns made his acquaintance, and has hit him off admirably in his poem, 'Hear, Land o' Cakes, and brither Scots.' The lines 'a chield's among you takin' notes, and faith he'll prent it,' are often quoted by persons ignorant of their original application. Grose crossed over to Ireland to continue the same inquiries, but died suddenly in an apoplectic fit at Dublin, 12th May 1791. Grose's work on the antiquities of Scotland appeared 1789–91; that of Ireland in 1791. Works of exceptional value are *A Classical Dictionary of the Vulgar Tongue* (1785; new ed. with Memoir by Pierce Egan, 1823), and *A Provincial Glossary* (1787). Other works are his *Treatise on Ancient Armour and Weapons* (1785–89); *Military Antiquities* (1786–88); *The Grumbler* (1791), a collection of amusing essays; and *The Olio* (1793), a strange hotch-potch of jests, verse, and prose essays.

Gross, Samuel David, American surgeon, was born near Easton, Pennsylvania, 8th July 1805, graduated at Jefferson Medical College, in Philadelphia, in 1828, and in 1835 became professor of Pathological Anatomy at Cincinnati. He was afterwards professor of Surgery in the universities

of Louisville and New York, and from 1856 to 1882 in Jefferson College. He died in Philadelphia, 6th May 1884. His published works are numerous and valuable, and include a *System of Surgery* (2 vols. 1859, 6th ed. 1882). Dr Gross was a member of many medical and surgical societies, both in America and in Europe, was president of the International Medical Congress at Philadelphia in 1876, and received the degree of D.C.L. from Oxford in 1872, and of LL.D. from Edinburgh in 1884.

Grossenhain, a busy town of Saxony, 21 miles by rail NNW. of Dresden. It has manufactures of cloth, buckskin, hosiery, nets, machinery, and cigars. Pop. (1875) 10,686; (1890) 11,938.

Grosseteste, Robert, Bishop of Lincoln, was born about 1175 at Stradbroke in Suffolk, of peasant parentage. *Grosseteste*, the French for 'great head;' Lat. *capito*) being a mere 'to-name.' Educated at Lincoln, Oxford, and Paris, he had for some years been the first teacher of theology in the Franciscan school at Oxford, and had held eight archdeaconries and other preferments, when in 1235 he was elected Bishop of Lincoln. He forthwith undertook in the most vigorous fashion the reformation of abuses, embroiling himself thereby first with his own chapter and next with Pope Innocent IV., whom he twice visited at Lyons, in 1244–46 and 1249–50. The pope granted English benefices to 'rascal Romans,' who drew indeed the revenues of their office, but never perhaps showed face in the country. This was intolerable to a man like Grosseteste, and he set himself strongly against it, incurring by his boldness a temporary suspension from the exercise of his episcopal functions, and a continual menace of excommunication. In the last year of Grosseteste's life, Innocent wrote to him ordering his nephew, a young Italian, to be promoted to the first canonry that should fall vacant at Lincoln, and accompanying his injunction with threats. The bishop was filled with indignation, and at once wrote a letter declaring that he would not obey such precepts even though they should issue from 'the highest order of angels,' and likening the pope's nepotism to the sin of Lucifer and Antichrist. Innocent, transported with fury, excommunicated him; but Grosseteste quietly appealed to Christ's own throne, and troubled himself no more about the matter. The feeling of the English nation sustained him; his clergy went on obeying him as if nothing had happened; and on his death at Buckden, near Huntingdon, 9th October 1253, Archbishop Boniface himself officiated at his funeral in Lincoln Cathedral. Such is the current account, against which Lingard objects that the mandate came not from the pope but the nuncio; that Innocent, on receiving Grosseteste's reply, not only rescinded the order, but adopted measures for the reform of these abuses; and that the story of Grosseteste's dying under sentence of excommunication rests on very questionable authority.

Grosseteste often is claimed as a pre-Reformation reformer; but his reforms were in the direction not of doctrine, but discipline. In politics he was a constitutionalist, a friend of Simon de Montfort. His learning was prodigious; Latin, Greek, Hebrew, French, mathematics, medicine, astronomy, mechanics, and music were among his attainments; whilst his knowledge of the Scriptures was profound. Pegge's catalogue of his works, of which only a few have been published, fills 25 closely-printed quarto pages, and exhibits 'treatises on sound, motion, heat, colour, form, angles, atmospheric pressure, poison, the rainbow, comets, light, as well as on the astrolabe, necromancy, and witchcraft.' See Brewer's *Monumenta Franciscana* (1858); Luard's edition of Grosseteste's Latin letters (Record Soc., 1862); and Perry's *Life and Times of Grosseteste* (S.P.C.K., 1871).

Grosseto, a little Tuscan town on the Ombrone, near its mouth, 160 miles SE. of Leghorn by rail, with a fine cathedral and old fortifications. Pop. 3962. Much marsh land in the Maremma has been drained and rendered healthy and fertile.

Grossglockner, the highest peak, 13,458 feet, of the eastern Alps and the centre of the range Hohe Tauern, is situated near the meeting-point of the frontiers of Tyrol, Carinthia, and Salzburg.

Grossulariaceæ, or Ribesiaceæ, a sub-order of Saxifragaceæ, including about 100 species, mostly all palæarctic or nearctic. See Currant and Gooseberry.

Grosswardein (Magyar *Nagy-Varad*), one of the oldest towns of Hungary, in the county of Bihar, is situated in a beautiful plain, on the Sebes (Rapid) Körös, 152 miles by rail SSE. of Pesth. Formerly a fortress, it is now the seat of a Roman Catholic and of a Greek bishop, has nineteen churches, and manufactures spirits, oil, vinegar, tiles, matches, pottery, and wine. Pop. (1870) 28,698; (1891) 38,219. In the neighbourhood is the Bishop's Bath, with alkaline sulphur-springs (104°–106° F.). At Grosswardein peace was concluded between Ferdinand I. of Austria and John Zapolya of Transylvania in 1538. It was taken and pillaged by the Turks in 1660, and remained in their hands until its recapture by the Austrians in 1692.

Grote, George, historian and politician, was born at Clay Hill, Beckenham, Kent, November 17, 1794. He was educated at the Charterhouse, and in 1810 became a clerk in the bank founded by his grandfather (a native of Bremen), Mr George Prescott, in Threadneedle Street. He remained in the bank for thirty-two years, devoting all his leisure to literature and political studies. He was an advanced Liberal in politics, and his first literary production was a reply to an article by Sir James Mackintosh in *The Edinburgh Review* on parliamentary reform. This was succeeded by a small work on *The Essentials of Parliamentary Reform*. Becoming acquainted with James Mill, Grote ultimately accepted his views on democratic government and church establishments; and many years before the passing of the Reform Bill of 1832 he laboured with a band of other ardent reformers in promulgating the views of Mill and Bentham and opposing both the Whigs and Tories. He further studied James Mill's system of political economy, and was not a little influenced in philosophy by the views of Comte. In 1820 he married Harriet, daughter of Thomas Lewin, of Bexley, a lady of considerable literary gifts, and their house in Threadneedle Street became a distinguished centre of political and philosophical thought. Encouraged by his friends the two Mills, John Austin, and Charles Buller, and strongly urged also by his wife, he conceived in 1823 the idea for his *History of Greece*. Mitford's history he mercilessly dissected at this time in the *Westminster Review*. Grote became head of the bank in 1830, and his position in the city, combined with his well-known talents, naturally pointed him out as a fitting representative of the Metropolis in parliament. In the election of 1832, consequent upon the passing of the Reform Bill, he stood for the City, and was returned at the head of the poll. During his first session in parliament he brought forward a motion for the adoption of the vote by ballot, his speech being remarkably able and incisive. The motion was lost by 211 to 106 votes, but Grote renewed it in the following session, and continued to advocate the measure until his abandonment of parlia-

mentary life in 1841. He sat for the City of London in three successive parliaments, but on each occasion by a diminished majority; and when he relinquished his seat the party of Philosophical Radicals with which he was associated had lost much of its influence.

Grote retired from the banking-house in 1843, and now devoted himself exclusively to literature, the *History of Greece* becoming the main object of his life. The first two volumes of the work appeared in 1846, and met with the general favour of all parties. The twelfth volume was issued in 1856, bringing down the subject to the end of the generation contemporary with Alexander, the period originally designed by the author. The history was translated into German and French, and was confessedly deserving of the high position to which it attained in literature. While it throws new light upon Greek history, and lucidly traces the progress of Hellenic thought, its martial passages are notable for their vigour, and its geographical details for their accuracy. Grote was appointed a trustee of the British Museum, and in 1864 foreign associate of the French Academy. He was elected president of University College, and vice-chancellor of London University, which offices he held until his death. In the latter capacity he rendered signal services to the university. In 1865 he concluded an elaborate work on *Plato and the other Companions of Socrates*, which, with his *Aristotle*, was supplementary to the *History of Greece*. The latter work, notwithstanding its lack of imagination, still remains unsuperseded for its graver qualities and for its completeness as an historical picture. In dealing with Plato he was less successful, failing to grasp the lofty idealism of the Greek philosopher; and his study of Aristotle, which gave promise of a closer appreciation, unfortunately remains unfinished. A sketch of Swiss history during the war of the Sonderbund possesses special interest from its comparisons between the small republics of Switzerland and the city states of ancient Hellas. Grote, who declined a peerage offered him by Mr Gladstone, died June 18, 1871, and was buried in Westminster Abbey, where a bust by Bacon commemorates him. His minor works were published by Professor Bain in 1873, with critical remarks on his intellectual character, writings, and speeches; and *Fragments on Ethical Subjects*, being a selection from his posthumous papers, in 1876. Mrs Grote (1792–1878) was the authoress of a *Memoir of Ary Scheffer* (1860), *Collected Papers in Prose and Verse* (1862), and *The Personal Life of George Grote* (1873). See, too, *Mrs Grote: a Sketch*, by Lady Eastlake (1880).

Grotefend, Georg Friedrich, the first who found a key to the decipherment of the cuneiform inscriptions, was born at Münden in Hanover, June 9, 1775, and had his education at the university of Göttingen. He filled scholastic appointments at Göttingen, Frankfort-on-the-Main, and Hanover, and died 15th December 1853. He wrote learned books and papers on Latin, Umbrian, and Oscan philology, coins of Bactria, &c., but made for himself an enduring fame by deciphering the cuneiform alphabet—an intuition of genius—first given forth in 1802. Later works on this subject were *Neue Beiträge zur Erläuterung der Persepolitanischen Keilschrift* (1837), and *Neue Beiträge zur Erläuterung der Babylonischen Keilschrift* (1840). See Cuneiform Inscriptions. His son, Karl Ludwig Grotefend, an eminent antiquary and historian, was born at Frankfort-on-the-Main, 22d December 1809, studied at Göttingen University, and filled from 1853 a post in the Royal Archives at Hanover. He died 27th October 1874. His works are of the greatest value for numismatics and Roman epigraphy, the chief being *Die Münzen der Griechischen, Parthischen, und Indoskythischen Könige von Baktrien* (1839), *Imperium Romanum tributim Descriptum* (1863), and *Chronologische Anordnung der Athenischen Silbermünzen* (1872). His historical papers are mostly contained in the *Zeitschrift des historischen Vereins für Niedersachsen* (1850–74).—Friedrich August Grotefend, nephew of the great Grotefend, was born at Ilfeld, 12th December 1798, studied at Göttingen University, and afterwards became a professor there. He died 28th February 1836. His writings are mostly solid contributions to Latin philology.

Grotesque, a style of classical ornament, so called, in the 13th century, from its having been discovered amongst the painted decorations found in the excavations made in the baths of Titus and other ancient Roman buildings, the Italian word *grotto* applying to any subterranean chamber. This light, fantastic style was much in favour during the Renaissance.

Groth, Klaus, a modern writer of Low German, was born at Heide in Holstein, 24th April 1819. After teaching for some time in his native village, he spent six years (1847–53) of literary activity in the island of Femern. It was at this time that he composed his masterpiece, *Quickborn* (1852, 15th ed. 1885), a collection of poems written in the Ditmarsh dialect, and dealing with life and nature in Ditmarsh, poems as fresh and simple as the subjects that inspired them. A continuation was published in 1871. Both in *Quickborn* and in the prose village tales *Vertelln* (1855–59) Groth used Low German with great skill and ease, and with a fine feeling for its artistic capabilities. His other works in the same dialect are *Rothgeter, Meister Lampun sin Dochder* (1862), an idyll; *Voer de Goern* (1858), children's rhymes; *Ut min Jungsparadies* (1876), three stories; and *Drei Plattdeutsche Erzählungen* (1881). He has also written poems in High German, *Hundert Blatter* (1854), which are not adjudged so successful as his Low German efforts. A warm lover of his native tongue, he claims for it a co-ordinate place with High German in the polity of languages, and has urged his views in *Briefe über Hochdeutsch und Plattdeutsch* (1858) and in *Mundarten und Mundartige Dichtung* (1873). After five years' wandering in Germany and Switzerland, Groth began to teach German language and literature at Kiel in 1858, and in 1866 was nominated professor of the same subjects at the university there. See Eggers, *Klaus Groth und die plattdeutsche Dichtung* (1885).

Grotius, Hugo, or Huig van Groot, Dutch jurist, was born at Delft, 10th April 1583. An extraordinarily precocious boy, Grotius entered the university of Leyden in his eleventh year, and there he enjoyed the advantage of studying under Joseph Scaliger. When only fifteen years old he entered public life, accompanying Olden Barneveldt, the grand-pensionary, on an embassy to France, where, notwithstanding his extreme youth, his talents and conduct gained him the favour of Henry IV. On his return next year he began to practise as a lawyer in the Hague; in 1607 he was appointed a provincial fiscal-general, and in 1613 pensionary of Rotterdam. But the religious disputes between the Remonstrants and their opponents were now at their height in Holland; Olden Barneveldt was the protector of the former, and Grotius supported them by his writings and influence. These theological strifes had, however, a political significance also. In 1618 Barneveldt and Grotius were arrested, tried, and condemned by the dominant party under Prince Maurice (see Barneveldt), Barneveldt to death, and Grotius to imprisonment for life in the castle of Lovenstein. He escaped, however, by the contrivance of his

wife, who managed to have him carried out of the castle in a chest used for the conveyance of books and linen, while she remained in prison in his stead. Grotius found refuge at Paris in 1621, and Louis XIII. bestowed upon him a pension of 3000 livres. But ten years later this pension was withdrawn from him. From his youth upwards Grotius had been a diligent student of jurisprudence; in 1604 he wrote a work entitled *De Jure Prædæ*, which, however, he did not publish, but which he seems to have steadily improved year after year, until finally he issued it as his masterpiece, *De Jure Belli et Pacis*, in 1625. This work, a piece of most excellent scholarship, at once established its place as a standard authority on international law, and such it remained for several generations (see INTERNATIONAL LAW). In 1634 Oxenstierna and Queen Christina induced Grotius to enter the Swedish service as ambassador at the French court, a post which he held until 1645. On his retirement he proceeded to Stockholm; but, finding the court as uncongenial as the climate, he was returning home to Holland when he was shipwrecked, and died at Rostock, on the 29th August 1645.

To the talents of an able statesman Grotius united deep and extensive learning. He was a profound theologian, perhaps the best exegete of his day—a distinguished scholar, an acute philosopher, a judicious historian, and a splendid jurist. He was one of the best modern writers of Latin verse, and likewise composed poems in the Dutch language. His best historical work is *Annales et Historiæ de Rebus Belgicis* (1657), written in a style that recalls Tacitus by its concise and pointed power. His theological productions bear the titles *Annotationes in Libros Testamentum* (1644); *Annotationes in Novum Testamentum* (1641–46); and *De Veritate Religionis Christianæ* (1627), translated even into several oriental languages, and remarkable for its clear arrangement, vigorous logic, and graceful style. It is an elegant treatise on Christian apologetics. Lehmann's *Hugonis Grotii Manes Vindicati* (1727) contains a good life and a complete bibliography of his works. See also Hely, *Etude sur le Droit de la Guerre et de la Paix de Grotius* (1875), and Butler's *Life* (1827). The *De Jure Belli* was translated into English by Whewell in 1853.

Grotta del Cane ('Grotto of the Dog'), a small cave near Naples, in the vicinity of Lake Agnano and of Puzzuoli, contains carbonic acid gas with 77 per cent. of carbonic acid. This cave was known to the ancients, and is described by Pliny. It derives its name from the practice of introducing into it small dogs, which are soon almost deprived of life by the gas that owing to its density clings to the floor of the cave; but they soon recover upon being restored to the open air.

Grottaglie, a town in the Italian province of Lecce, 12 miles ENE. of Taranto, with 8880 inhabitants, who carry on wine-growing, bee-keeping, and silk and cotton weaving.

Grotte, LE, a town of Sicily, in the province of Girgenti. Pop. 8775, mostly employed in the sulphur-works of the district.

Grouchy, EMMANUEL, MARQUIS DE, French general, born at Paris, 23d October 1766. Entering the army at fourteen, he threw in his lot with the Revolution, and had his first taste of serious work in helping to suppress the Vendean revolt. After being nominated second to Hoche for the abortive expedition to Ireland, though Grouchy did enter Bantry Bay, he proceeded to join Joubert in Italy in 1798. Under Moreau, he greatly distinguished himself in Piedmont, and at Novi was taken prisoner, but subsequently exchanged (1799). Later he fought with conspicuous gallantry at Hohenlinden, Eylau, Friedland, Wagram, and in the Russian campaign of 1812, being appointed during the memorable retreat leader of the 'sacred' bodyguard of Napoleon. After the disastrous battle of Leipzig, Grouchy covered the retreat of the French on the west side of the Rhine. Amongst the first to welcome Napoleon after his escape from Elba, Grouchy destroyed the Bourbon opposition in the south of France, and then, hastening north, routed Blucher at Ligny. After the defeat at Waterloo and the second abdication of Napoleon, Grouchy, appointed by the provisional government commander-in-chief of the broken armies of France, led them skilfully back towards the capital; then, resigning, he betook himself to the United States. He returned from exile in 1819, and was reinstated as marshal in 1831. His death occurred at St-Etienne on 29th May 1847. See his *Memoires*, edited by his grandson (5 vols. 1873–74).

Ground-annual, in the law of Scotland, is an annual payment, sometimes called a rent-charge, made for land. It may be regarded as a substitute for feu-duty, and is little known where the law allows the constitution of a feu-duty. Thus, when a vendor sells his land, and instead of taking a lump sum for the price, prefers a sum by way of a perpetual annuity or rent, he conveys the land in fee to the disponee or purchaser, subject to this ground-annual, which is a burden on the lands transferable and extinguishable like other real burdens. The vendor is then called the ground-annualer, and if the ground annual is not paid he is entitled as a remedy to poind the ground—i.e. seize all the goods, whether of the owner or his tenants, which are found on the lands, and pay himself, and raise action of maills and duties against the tenant, or he may sue the debtor.

Ground-game. See GAME LAWS.

Ground-ice. See ANCHOR ICE.

Ground-ivy (*Glechoma hederacea*, united with the genus Nepeta by some botanists as *N. Glechoma*), a plant of the natural order Labiatæ, a common native of Britain and other parts of Europe, growing in waste places, plantations, hedges, &c., in a dry soil. It has a creeping stem, kidney-shaped crenate leaves, and axillary blue flowers growing in threes. A tea prepared from the leaves is in great repute among the poor in many places, and the plant is supposed to be stimulant, aromatic, and of use in pectoral complaints. The leaves were formerly used in England for clarifying and flavouring ale, which was then called Gill-ale or Gell-ale, from Gill or Gell, an old name of this plant; but this use has been discontinued since the introduction of hops.

Groundling (*Cobitis tænia*), the spinous loach, a little cyprinoid fish resembling the loach, from which it is distinguished by a forked erectile spine beneath the eye, and by its more compressed form. It is rare and very local in Britain, frequenting the muddy parts of rivers, habitually keeping close to the bottom. The genus is known to include only two other species.

Ground-nut, GROUND BEAN, or PEA NUT, the fruit of *Arachis hypogæa*, an annual plant belonging to the natural order Leguminosæ, extensively cultivated in southern North America, but supposed to be a native of Africa. The name *Arachis*, *Aracos*, or *Aracidna*, was given by Pliny to a plant which was stemless and leafless, being all root. Modern botanists have given the name to a species which ripens its fruit underground. The pods, though first formed in the air, are as they increase in size forced into the earth by a natural

motion of their stalks, and there come to maturity 3 or 4 inches under the surface, hence the popular name Ground or Earth-nut. In the southern states of North America the seeds, or nuts, as they are called, are roasted and used as chocolate. When fresh they have a sweet taste resembling almonds. They are a favourite article of food with the negroes. A fixed very sweet oil is extracted from the seeds, which is considered by some equal to olive-oil, and it does not become rancid, rather improving with age. Ground-nuts are to be met with occasionally in fruiterers' shops in Britain, and some attempt has been made to cultivate the plant around Paris; but requiring as it does to be reared in hot-beds, expense and trouble have circumscribed its adoption as a commercial production there. It is, however, cultivated in some of the warmer countries of the south of Europe.—The roots of *Bunium bulbocastanum* and *B. flexuosum* are also known as ground-nuts or Earth-nuts (q.v.).

Ground-nut (*Arachis hypogæa*).

Ground Pigeon, a name widely applied to those numerous pigeons (Columbidæ) which are terrestrial rather than arboreal. The more thoroughly ground-loving forms have short and rounded wings, and lessened power of prolonged flight, but possess long legs and a rapid pace. See Elliot, *Standard Natural History*, vol. iv. Boston, 1885), for an admirable account.

Ground-rent, in the law of England, is the rent which a person, who intends to build upon a piece of ground, pays to the landlord for the use of the ground for a certain specified term, usually ninety-nine years. The builder usually pays a certain annual sum by way of rent to the owner, who is thereafter called the ground-landlord, and then commences to build upon the land. The builder then lets the houses, and in doing so he of course includes in the rent which he puts upon each house a proportionate part of this ground-rent, which he himself is bound to pay to the ground-landlord, so that practically the tenant pays both the rent and the ground-rent, the latter being so called because it issues out of the ground, independently of what is built upon it. Ground-rents often form a safe investment for capital, because the security is good. This security consists in the ground-landlord being able, whenever his ground-rent is in arrear, to distrain all the goods and chattels he finds on the premises, to whomsoever they may belong; and as the ground-rent is generally a small sum, compared with the furniture of the tenant, he is always sure to recover its full amount. This power of distress exists (except in the case of lodgers) whether the tenant has paid his rent to his own landlord or not; but if at any time the tenant has been obliged to pay the ground-rent which his landlord ought to pay, he may deduct such sum from the next rent he pays, and set off the one against the other so far as it will go. At the end of the ninety-nine years, or whatever other term is fixed upon, the building becomes the property of the ground-landlord, for the interest of the builder (or mesne landlord as he is called) then expires by the effluxion of time. The value of the property thus reverting to the ground-landlord is often greatly increased by municipal improvements effected at the expense of the rates—i.e. at the expense of the occupier who pays the rates. The justice of this arrangement is open to question, and the case for a readjustment of rates is generally admitted to be a strong one. There are some politicians who announce that they will accept this reform as a mere instalment; their ultimate aim is to 'nationalise' the land by taxing ground-rents at the rate of twenty shillings in the pound.

Ground-rent corresponds to *feu* in Scotland, with this difference, that the feu-rent in the latter case lasts for ever, there being no definite term fixed for its ceasing.

Groundsel, the common name of those species of Senecio (q.v.) which have small heads of flowers either destitute of ray or with the ray rolled back. The Common Groundsel (*S. vulgaris*), which is usually destitute of ray, is one of the most plentiful of weeds in waste and cultivated grounds in Britain and most parts of Europe, and now also diffused, through European commerce and colonisation, throughout the world. It is a coarse-looking annual, of rapid growth, about a foot high, branched, with pinnatifid leaves, and small yellow heads of flowers; flowering at all seasons, even in winter, when the weather is mild; its seeds being also widely diffused by means of their hairy pappus. It has a rather disagreeable smell; but birds are very fond of the young buds and leaves, and cage-birds are fed with them. It is also eaten by cattle if better fodder be scarce. It has a saltish taste, whence its name; and is of old repute in domestic medicine for poulticing. The other British species are weeds of very similar appearance, but are stronger, having a more disagreeable odour, and are viscid to the touch. Groundsel has been introduced into the United States, and is now found as a weed in gardens and waste places from New England to Pennsylvania.—Like other annual weeds, the groundsels ought to be hoed down or pulled as they appear, when the ground is in crop.

Ground Squirrel. See CHIPMUNK.

Grouse, a name applied to many game-birds in the family Tetraonidæ, which also includes quails and partridges. From these the grouse (forming a sub-family Tetraoninæ) may be distinguished by the more or less complete feathering of nostrils, legs, and feet, by a bare patch of skin over the eye, by a comb-like fringe on the sides of the toes, and sometimes by a distensible sac on the side of the neck. They are well known to be large, plump, somewhat heavy birds, usually short-tailed, and with beautifully-variegated plumage, which must often be protective. They are especially abundant in the northern parts of both Old and New World.

We shall first take a brief review of most of the important forms, some of which receive separate notice. (1) The genus Tetrao is well represented by the Capercailzie (q.v.; *T. urogallus*), its Siberian relative *T. urogalloides*, and the Black-cock (q.v.) or Black Grouse (*T. tetrix*), well known in Britain. (2) The Ptarmigans (q.v.) belong to the genus Lagopus, distinguished by their heavily-feathered toes, and (with the exception of the next species) by the snow-white winter plumage. The Red Grouse (*L. scoticus*) is indigenous only to

Britain, represented by the Willow Grouse (*L. albus*) in other northern countries. (3) The ruffed grouse, in the genus Bonasia, are exceptional in having the lower part of the leg bare, and can elevate the soft feathers on the sides of the neck. Well known is the American species *B. umbellus*, with several varieties. They frequent woods, roost in trees, nest on the ground, and fly straight and swiftly. The male is famous for his habit of 'drumming.' 'He stands upon a trunk of some fallen tree, and, stretching himself into a horizontal position, beats stiffly downwards with his wings, slowly at first, increasing the strokes until they become so rapid that the wings are invisible. This loud drumming noise is heard even after the limits of the breeding season. An allied species, the Hazel Grouse (*B. betulina*), is widely distributed in Europe and Asia, but is without ruff or drumming. Along with two other species it is sometimes ranked in a separate genus, Tetrastes.

(4) Among the numerous North American grouse, besides species of Bonasia and Lagopus, there are first of all several forms nearly related to, if not included within the genus Tetrao. The 'Blue Grouse' (Dendragapus) inhabit evergreen forests at a high elevation; the males emit in spring a prolonged whirring sound from the contraction of two dilatable sacs on the neck. The flesh is white and delicate. The Spruce Grouse (Canace) are represented by several species—'forest- and swamp-loving birds, very tame and unsuspicious, with dark and generally bitter flesh.' Well known are the Prairie Hens or Prairie Chickens, of which *Cupidonia*, or sometimes *Tetrao cupido*, is the commonest, though in process of rapid extermination even in spite of the laws. It is rather smaller than a blackcock, reddish-brown in colour, with beautiful markings of black and white, and bears on the sides of the neck two large dilatable sacs, hidden by erectile feathers, and producing by their expansion and contraction loud 'booming' sounds, which, as well as the combats between rival males, enliven the breeding season. The flesh is much esteemed, and the bird is ruthlessly persecuted. Nearly related, but with less-developed neck sacs, is the sharp-tail grouse, referred to the genus Pediœcetes. The largest American grouse, however, is the Cock of the Plains or Sage Cock (*Centrocercus urophasianus*), the male of which approaches our capercailzie in size, though not by any means in weight. It is dispersed over the western plains, and, according to Elliot, owes the bitter unpalatable character of its flesh to its diet of Artemisia or 'wild sage' which abounds in these desert regions. The tail is remarkably long, the neck sacs very large, the usually hard gizzard portion of the stomach remains soft. As the Sand grouse (Pteroclidæ)—one of which, Pallas's Sand-grouse (*Syrrhaptes paradoxus*), has been coming in increasing numbers to Britain since 1859—are not grouse, if indeed even gallinaceous, they must be noticed separately.

Returning now to British grouse (Tetraonidæ), we have to deal with (1) the Capercailzie (*Tetrao urogallus*), (2) the Blackcock (*T. tetrix*), (3) the rare Ptarmigan (*Lagopus mutus*), and (4) the Red Grouse (*L. scoticus*). The first three are separately discussed; it remains to notice briefly the last, which is in a special sense the British grouse. This is strictly an insular ptarmigan which does not change its colour, and is very nearly related to the Willow Grouse (*L. albus*) of the Continent. It is widely distributed on the moors in the north of England, in Ireland, but above all in Scotland. The male measures 16 inches, and is predominantly reddish and chestnut-brown with some black and white. The female is rather smaller, and with more of the light chestnut plumage. The colour varies considerably in different localities. Pairing occurs in early spring; the nest is slight, and on the ground usually among heather; the eggs (eight to ten) are 'of a buffish white ground colour,

The Red Grouse (*Lagopus scoticus*).

mottled with rich red or brown.' The female sits very close, and the male gives warning of danger. The birds feed on leaves and fruit of bilberry, tips of heather, sedge seeds, and the like.

Grouse are well known to be subject to a decimating disease, but neither in regard to the direct or indirect conditions of the epidemic is there any certainty. It was first noticed (1815-20) about the time when shootings began to be let and protection or over-preservation became common. Atmospheric conditions, sheep, sheep-wash, heather-blight, &c. have been blamed, while John Colquhoun, author of *The Moor and the Loch*, strongly maintained that the indirect cause was simply over-preservation. The destruction of birds of prey, which used to kill off unhealthy birds, must certainly have its nemesis. Tapeworms are often found in grouse, but are not regarded as of much import; a round worm (Strongylus) is possibly more injurious; most probably, however, the disease is due to bacteria of some sort, and runs riot in unnatural conditions.

Grouse-shooting has long been a popular sport with those living where the birds abounded, but it was not till near the middle of the 19th century that Southrons began to flock into Scotland for this sport, and shooting rents to grow rapidly. In many districts the 12th of August is the most important date in the year. Many thousands of acres now bring their owners large rents for grouse-shooting; there are said to be in Scotland in all, besides deer-forests, some 2400 separate shootings, on most of which grouse are found. Grouse occur in every Scottish county, but Perthshire is the chief grouse-shooting region. An area of 10,000 acres well stocked with birds, and having a shooting lodge, can hardly be leased for less than £500 per annum (*Outdoor Sports in Scotland*, 1889); if there be salmon and ground-game, the rent may be £600. The rents may be said to run from tenpence to half-a-crown an acre. In a good season, 500,000 brace may be shot. It is computed that every brace costs the sporting tenant a sovereign. Hence if each of the 2400 grouse-moors yield each on an average 200 brace, the total (960,000 birds) would represent a grouse-shooting rental for Scotland of £480,000.

See Blackcock, Capercailzie, Ptarmigan, Sand-grouse; also D. G. Elliot, *The Tetraonidæ* (New York, 1864-65); also in *The Riverside or Standard Natural History*, edited by J. S. Kingsley (Lond. and Boston); A. B. Meyer, *Unsere Auer-, Birk- und Rackwild* (Vienna, 1887, folio atlas with 17 plates of grouse); R. W. Shufeldt, *Osteology of North American Tetraonidæ*, Bull,

U.S. Geol. Geogr. Surv. vi. (1881–); manuals of Yarrell, Howard Saunders, &c.; Colquhoun, *The Moor and the Loch* (1851, 6th ed. 1884); Lord Walsingham and Sir R. Payne-Gallwey, *Shooting* (Badminton Lib. 1886); 'Ellangowan,' *Outdoor Sports in Scotland* (1869). For disease, see *Zoologist*, *Rep. Brit. Assoc.*, and *Journ. Roy. Micr. Soc.*; Chapman, *Bird Life on the Borders* (1889); Klein, *Etiology and Pathology of Grouse Disease* (1892).

Grove, Sir George, born at Clapham in 1820, was trained as a civil engineer, and erected in the West Indies the first two cast-iron lighthouses built. As a member of the staff of Robert Stephenson, he was employed at the Chester general station and the Britannia tubular bridge. He was secretary to the Society of Arts from 1849 to 1852, and secretary to the Crystal Palace Company from 1852 to 1873, where he subsequently became a director. It is for his services to literature and music that Sir George is best known. As editor of *Macmillan's Magazine*, as a large contributor to Smith's *Dictionary of the Bible*, and as editor (and part author) of the great *Dictionary of Music and Musicians* (4 vols. 1878–89), he has served the reading public; and these and his zeal and success in promoting the love of good music secured for him the degree of D.C.L. from Durham University in 1872, and LL.D. of Glasgow in 1886. He was knighted in 1883 on the opening of the Royal College of Music, of which he was made Director—a post he resigned in 1895. He was founder of the Palestine Exploration Fund, published *Beethoven and his Nine Symphonies* in 1896, and was a contributor to this Encyclopædia. He died 29th May 1900.

Grove, Sir William Robert, lawyer and physicist, was born at Swansea, 11th July 1811. He studied at Brasenose, Oxford, and in 1835 was called to the bar; in 1871 he was raised to the bench, receiving knighthood in 1872; and by the Judicature Act (1875) becoming a judge in the High Court of Justice. He retired from the bench in 1887. He greatly distinguished himself in the subjects of electricity and optics, and was professor of Natural Science at the London Institution from 1840 to 1847. In 1839 he invented the powerful voltaic battery known by his name. He contributed extensively to scientific journals, and published several very important lectures, as those on the Progress of Physical Science (1842), in which he propounded the theory of the mutual convertibility of the natural forces, on the assumption of their all being modes of motion; the Correlation of the Physical Forces (1846), a development of the same views; Voltaic Ignition (1847); and the Continuity of Natural Phenomena (1866). He was president of the British Association in 1866, and was a Fellow of many learned societies. He died on the 3d August 1896.

Groves. See Ashera, Tree-worship.

Growler (*Grystes salmonoides*), a fish of the Perch family, abundant in many of the rivers of North America, as in the neighbourhood of New York. It attains a length of 2 feet, affords good sport to anglers, and is much esteemed for the table. It is of an olive colour, dark on the upper parts, and becoming grayish-white beneath. It receives its name from a sound which it emits. The genus Grystes has small scales, and only fine villiform teeth. Nearly allied is the genus Oligorus, including the valuable Murray Cod (*O. macquariensis*) from the Murray and other rivers of South Australia, which may attain a length of 3 feet and a weight of 100 lb., and a New Zealand coast form, the 'Hapuku' (*O. gigas*).

Groyne, The, a sailor's name for Coruña (q.v.).

Grub, a name generally applied to the worm-like larvæ of insects when they have a distinct head but no legs—e.g. in bees and some beetles. In distinction therefrom, a larva without distinct head and without limbs, as in Diptera, is a *maggot*, but with distinct head and limbs, anterior as well as posterior, is a *caterpillar*. But these are all somewhat rough and ill-defined titles, now replaced by a more exact terminology (see Insects and Larva). The economic importance of many grubs, especially those of some beetles, is well known. See Corn Insects.

Grubber, an agricultural implement consisting of a framework of cast or wrought iron, in which are fixed *tines* or teeth, somewhat like those of a harrow, but curved, and so placed as to enter the ground somewhat obliquely when the implement goes forward; the whole moving on wheels, by which the depth to which the teeth may penetrate is regulated.

Gruber, Johann Gottfried, German author, born at Naumburg on the Saale, 29th November 1774, studied at Leipzig, and in 1811 was appointed professor at the university of Wittenberg, and in 1815 professor of Philosophy at Halle. He died 7th August 1851. His chief work was that of editing, first with Ersch, and after his death alone, the first section (A to G) of the *Allgemeine Encyklopädie* (see Encyclopædia). Of his independent works we mention *Charakteristik Herders* (1805), *Geschichte des menschlichen Geschlechts* (1805), and lives of *Wieland* (1815–16) and *Klopstock* (1832); he also edited *Wieland's Sämmtliche Werke* (1818–28).

Grub Street, thus described in Dr Johnson's *Dictionary:* 'Originally the name of a street near Moorfields in London, much inhabited by writers of small histories, dictionaries, and temporary poems, whence any mean production is called *Grub-Street.*' Andrew Marvell used the name in its opprobrious sense, which later was freely used by Pope, Swift, and the rest. The name has been changed into Milton Street, from the neighbourhood of the Bunhill residence of the poet. One of the most entertaining of the old newspapers is the *Grub Street Journal*, which ended with its 418th number, December, 29, 1737, the principal writers of which are supposed to have been Dr Richard Russel and Dr John Martyn, and which was used, if not by Pope himself, at least by his party, as a vehicle for attacks against the Dunces.

Gruel is a mild, nutritious, easily-digested article of food. To prepare it, put a teacupful of oatmeal into a pint of water; after standing twenty minutes pour off the water, rejecting the coarse parts of the meal; boil the water twenty minutes. It may be flavoured according to taste; butter should not be added if the gruel is meant for invalids. Gruel is more nourishing than preparations from arrowroot, sago, tapioca, and other starchy substances.

Grün, Anastasius. See Auersperg.

Grünberg, a town of Prussian Silesia, 34 miles NW. of Glogau by rail, is surrounded by vine-clad hills, and manufactures wine (since 1150), woollen goods, twine, machinery, &c. Pop. 14,396.

Grundtvig, Nikolai Frederik Severin, Danish poet and theologian, was born at Udby, in Zealand, 8th September 1783. He first became known as the author of *Northern Mythology* (1808; 3d ed. enlarged and revised, 1870) and *Decline of the Heroic Age in the North* (1809). These were followed in 1814 by the *Rhyme of Roeskilde* and the *Roeskilde Saga*, and in 1815 by a collection of patriotic songs (*Kvadlinger*). About the same time he took his stand as a witness against the current irreligion and rationalism. As time went on he became the head of a religious school, the Grundtvigians, who strove to free the church from the interference of the state, and to approximate to

the ideal of independent religious communes. His religious views got firm hold of the hearts of the people throughout the three countries of Scandinavia. Besides this he was instrumental in raising the educational condition of the peasantry. In 1825 Grundtvig, for a vehement attack upon one of the chief representatives of the prevalent rationalism, was fined and suspended from preaching, the suspension lasting until 1832. During all these years his pen was never idle. In 1818 he had begun the translation into Danish of Snorri Sturluson and Saxo Grammaticus; and in 1820 he published a Danish translation of the Anglo-Saxon poem *Beowulf*. As a writer of secular and sacred poetry he stands high in his countrymen's regards; his son published his *Poetiske Skrifter* (6 vols.) in 1880-85. From 1839 Grundtvig preached in the church of Vartov Hospital in Copenhagen, after 1861 with the title of bishop, though he held no see. He died 2d September 1872. The works of his later years include *The Seven Stars of Christendom* (1860; 3d ed. 1883) and *Church Mirror* (1871), a collection of addresses. His son, SVEND HELGE (1824-83), from 1869 professor of Scandinavian Philology at Copenhagen, edited *Danmarks Gamle Folkeviser* (1853-83), other collections of folk tales, and *Sæmund's Edda* (1868; 2d ed. 1884).

Grundy, Mrs, the invisible *censor morum* appealed to in the phrase, 'But what will Mrs Grundy say?' in Morton's play *Speed the Plough* (1800).

Grundy, SYDNEY, born in Manchester 23d March 1848, was called to the bar. In 1876 he published a 3-volume novel, *The Days of his Vanity*; but has since become known as a successful playwright, having produced *The Glass of Fashion* (1883), *A Fool's Paradise* (1890), *A White Lie* (1893), *Sowing the Wind* (1893), and *The New Woman* (1894). Many (like *A Pair of Spectacles*) are adaptations from the French.

Gruyère, a little town of Switzerland, 16 miles SSW. of Freiburg, gives its name to the famous cheese of the whole canton of Freiburg. Pop. 1200.

Gryllus, a Linnean genus of insects of the order Orthoptera, answering to the section Saltatoria (Lat., 'leapers') of later entomologists, and containing crickets, grasshoppers, locusts, &c. The genus is now restricted to the true crickets—e.g. *G. domesticus* and *G. campestris*, while the family Gryllidæ is defined to include a not very large number of related genera, such as the mole cricket (Gryllotalpa). See CRICKET, GRASSHOPPER, LOCUST.

Gryphius, SEBASTIAN, a famous printer, born at Reutlingen, in Swabia, in 1493. He came as a youth to Lyons, and died there in 1556, having between 1528 and 1547 issued above 300 works, notable for their accuracy and the large clear type in which they were printed. Gryphius preferred a large bold Italic type. Amongst the more noted works are the fine Latin Bible of 1550, and Dolet's *Commentaria Linguæ Latinæ* (1536). The original German spelling of the Latinised name Gryphius is *Gryph*, the French *Gryphe*. The well-known emblem on Gryphius's publications is a griffin. Gryphius's sons, Antoine and François, were also famous French printers.

Gsell-Fels, THEODOR, author of the excellent guide-books for Italy, was born at St Gall in 1819, and has laboured with equal success as a medical man in various towns (Würzburg, Berlin, Vienna, Zurich, &c.) and as a lecturer on Italian art (chiefly at Basel). His thorough knowledge of Italy, its history and its art treasures, is brilliantly illustrated in his four guide-books to that country—'Oberitalien,' 'Mittelitalien,' 'Rom und die Campagna,' 'Unteritalien und Sizilien'—which are published as *Meyer's Reisebücher*. Gsell-Fels has also published works on the baths and sanatoria of Switzerland (2d ed. 1885), and Germany (1885), and edited a guide-book on South France.

Guacharo, or OIL-BIRD (*Steatornis caripensis*), a remarkable South American bird, with characters which seem to unite it to owls and goatsuckers, but differing from the latter in having a strong bill, and being frugivorous. The food of the guacharo consists of hard and dry fruits. It is about the size of a common fowl; the plumage brownish gray, with small black streaks and dots. The guacharo is a nocturnal bird, a circumstance very singular among

Guacharo (*Steatornis caripensis*).

frugivorous birds. It spends the day in deep and dark caverns, where great numbers congregate and make their nests. It was first known from Venezuela, but has since been discovered in Peru, Trinidad, and elsewhere in the northern South American region. Humboldt gives a most interesting account, in his Personal Narrative, of a visit to the great Guacharo Cavern in the valley of Caripe, near Cumana. This cavern is visited once a year for the sake of the fat of the young birds, which are slaughtered in great numbers, and their fat melted and stored for use as butter or oil. The clarified fat is half liquid, transparent, inodorous, and will keep for a year without becoming rancid.

Guaco. See ARISTOLOCHIA.

Guadalaja'ra, (1) an old and decayed town of Spain, capital of the province of the same name, on the Henares, 35 miles NE. of Madrid by rail, with some unimportant manufactures of flannel and serge, and a royal college of engineering. Here is the quaint, neglected palace of the Mendozas, whose tombs, in the *Panteon* below the chapel of San Francisco, were barbarously mutilated by the French. Pop. 8524.—The *province* occupies the northern part of New Castile (see CASTILE), is in the great central plain, and has an area of 4870 sq. m., with a pop. of 203,000.—(2) Capital of the Mexican state of Jalisco, and the third city of the republic, lies in a fertile valley by the Rio Grande de Santiago, here crossed by a fine bridge of 26 arches, 280 miles WNW. of Mexico city, with which the place is connected by rail. Though most of the houses are of only one story, the town presents a pleasing appearance, with wide streets crossing at right angles, numerous public squares, and a fine shaded *alameda*; there are several lines of tramway, and water is supplied by an aqueduct over 20 miles long. Guadalajara is the seat of an archbishop, and possesses a handsome cathedral, besides the government palace, a mint, university, hospitals, and school of art. Its industries are important: it is the chief seat of the cotton and woollen manufactures of the country; and the Guadalajara

pottery and metal wares, like the confectionery, have a reputation all over Mexico. Pop. (1895) 95,000.

Guadalaviar (anc. *Turia*), a river of eastern Spain, has its source near that of the Tagus, in the south-west of Aragon, and after a course of 190 miles, in a generally south-south-east direction, falls into the Mediterranean at Grao, 1½ mile below Valencia. In passing through the beautiful Huerta de Valencia, it is divided, for purposes of irrigation, into numerous channels.

Guadalquivir (Arab. *Wádi-al-Kebir*, 'the great river;' anc. *Bætis*), the most important river of Spain, and the only one that, fed by the rains in winter and the Sierra Nevada's melting snows in summer, presents at all seasons a full stream. It rises in the Sierra de Cazorla, in the east of the province of Jaen, flows in a general south-west direction through the provinces of Jaen, Cordova, Seville, and, forming the boundary for about 10 miles between the provinces of Huelva and Cadiz, falls into the Gulf of Cadiz at San Lucar de Barrameda, after a course of 374 miles. Strelbitsky estimates its drainage area at 21,580 sq. m. The principal towns on its banks are Cordova and Seville, to the last of which, about 80 miles above its mouth, the river is navigable for steamers. Below Seville it twice divides itself into two branches, forming two islands—the Isla Menor and the Isla Mayor. Its chief affluents are the Guadajoz and the Jenil on the left, and the Guadalimar and the Guadiato on the right. At Montoro it breaks through the outlying spurs of the central Sierra Morena in a series of rapids, but its lower course is sluggish and dreary in the extreme; the stream itself is turbid and muddy, and eats its way through an alluvial level given up to herds of cattle and to waterfowl. There are no villages in this district, which, though favourable to animal and vegetable life, is fatal to man, from the fever and ague caused by the numerous swamps. During the equinoctial rains the river rises sometimes 10 feet, and the country is yearly flooded as far up as Seville, to which point the tide is noticeable.

Guadalupe Hidalgo, 5 miles by tramway N. of Mexico city, is the chief place of pilgrimage, and its brick cathedral the richest in all Mexico; for here is preserved a miraculous picture of a brown Virgin, painted on a peasant's coarse cloak. The treaty which ended the war with the United States was signed here, 2d February 1848.

Guadeloupe, one of the Lesser Antilles in the West Indies, and the most important of those which belong to France, lies about 77 miles N. by W. of Martinique, and contains, including dependencies, 494 sq. m., with a pop. in 1895 of 168,000, mostly blacks and mulattoes. It is divided into Grande-Terre on the east, and Basse-Terre or Guadeloupe proper on the west, by a strait of from 40 to 150 yards in width, which bears the name of Salt River, and is navigable only for vessels of very light tonnage. The nomenclature of the two islands appears curiously perverse, for Basse-Terre is the loftier of the two, and Grande-Terre is the smaller; consequently the name Basse-Terre is now generally applied solely to the capital (pop. 7600), a town of officials mainly, in the south-west of the island. Grande-Terre, generally low, is of coral formation; Basse-Terre, on the contrary, is traversed by volcanic mountains, which culminate in La Soufrière (the 'Sulphur Mine') at a height of 5497 feet. Earthquakes are frequent, and in the towns the houses are now built of wood or iron. The chief product of the island is sugar; coffee also is exported. The annual commerce, including imports and exports (about equal) exceeds £2,000,000; more than half of this trade is with France. Point-à-Pitre (q.v.) is the principal town and port; Le Moule, on the eastern coast of Grande-Terre, has 8500 inhabitants, and Grand-Bourg, on Marie-Galante, 7300. The colony is administered by a governor, assisted by a general council; primary education is free and compulsory, and there is a good *lycée* at Point-à-Pitre. The dependencies of Guadeloupe are the neighbouring islets of Désirade, Marie-Galante, and Les Saintes, besides St-Barthélemy and part of St-Martin to the north-west. Guadeloupe was discovered by Columbus in 1493, but it was not till 1635 that it was colonised by the French; and after repeatedly falling into the hands of England, during her wars with France, it was at length permanently ceded to the latter power in 1816.

Guadiana (Arab. *Wádi Ana*, the anc. *Anas*), one of the five principal rivers of the Iberian peninsula, formerly regarded as rising in the desert Campo de Montiel, where a stream which drains the small Lagunas de Ruidera flows north-west and disappears within a few miles of the Zancara. It was long believed that this stream reappeared in a number of springs and lakes that rise some 22 miles to the south-west, known as the *Ojos* ('Eyes') of the Guadiana, and connected by a small stream with the Zancara; but it has now been ascertained that the waters which disappear higher up find a short underground way to the Zancara, which is therefore the true Upper Guadiana. Rising in the east of the plateau of La Mancha, it flows at first south and west to the *Ojos*, below which point it receives the name of the Guadiana. It follows a sinuous westerly course as far as Badajoz, then bends southward, forms for some miles the boundary between Spain and Portugal, and flows through part of the province of Alemtejo, returning to form the frontier again, until it empties into the Gulf of Cadiz. It is about 510 miles in length, but is navigable only for about 42 miles. Its chief affluents are the Jabalon, Zujar, Matachel, Ardila, and Chanza, all on the left.

Guaiacum, a genus of trees of the natural order Zygophyllaceæ, natives of the tropical parts of America. The flowers have a 5-partite calyx, five petals, ten stamens, and a tapering style; the fruit is a capsule, 5-angled and 5-celled, or the cells by abortion fewer, one seed in each cell. The trees of this genus are remarkable for the hardness and heaviness of their wood, known variously as *Lignum Vitæ*, as *Guaiacum-wood*, and as *Brazil-wood*; as well as for their peculiar resinous product, *Guaiacum*, often but incorrectly called a gum. The species to which the commercial Lignum Vitæ and Guaiacum are commonly referred is *G. officinale*, a native of some of the West India islands, and of some of the continental parts of America; a tree 30 or 40 feet high, leaves abruptly pinnate, with two or three pairs of ovate, obtuse, and perfectly smooth leaflets, pale blue flowers in small clusters, which are succeeded by compressed roundish berries, a furrowed bark, and generally a crooked stem and knotty branches. It seems probable, however, that other species, as well as this, supply part of the guaiacum-wood and resin of commerce. At present they are obtained chiefly from Cuba, Jamaica, and St Domingo. The wood is imported in billets about 3 feet long and 1 foot in diameter, of a greenish-brown colour. This is the colour of the heart-wood; the sap-wood is pale yellow. Guaiacum-wood is remarkable for the direction of its fibres, each layer of which crosses the preceding diagonally; annual rings are scarcely to be observed, and the pith is extremely small. It sinks in water. It is much valued, and used for many purposes, chiefly by turners; ships' blocks,

rulers, pestles, and bowls (see BOWLS) are among the articles most commonly made of it. When rubbed or heated, it emits a faint disagreeable aromatic smell; its taste is also pungent and aromatic. Shavings and raspings of the wood are bought by apothecaries for medicinal use. The bark is also used in medicine on the continent of Europe, although not in Britain. The virtues of both wood and bark depend chiefly on the resin which they contain, and which is itself used in powder, pill, and tincture. It is an acrid stimulant, and has been employed with advantage in chronic rheumatism, in chronic skin diseases, in certain cases of scanty and painful menstruation (and hence it is occasionally an effectual remedy in cases of sterility), and in chronic catarrh. It has also been highly praised as a preventive of gout. The resin is an ingredient of the well-known *Plummer's Pills*. In the 16th and 17th centuries Guaiacum was the remedy most in repute for syphilis. It is used in testing Blood-stains (q.v.). The resin sometimes flows spontaneously from the stem of the Guaiacum tree; it is sometimes obtained artificially. It is of a greenish-brown colour, and has a brilliant resinous fracture.

Guaiacum officinale.

It has scarcely any taste, but leaves a burning sensation in the mouth. One of its most striking characteristics is that it is coloured blue by its oxidising agents. It contains *guaiacic acid*, $HOC_{13}H_7O_3$, which closely resembles benzoic acid, and yields, on distillation, certain definite compounds known as *guaiacen*, *guaiacol*, and *hydride of guaiacyl*.

Guaira, LA, the port of Caracas (q.v.), on a narrow, shadeless strip of land between the mountains and the Caribbean Sea. Efforts have been made to improve the harbour by the construction of a breakwater and wharves. The average value of the imports is almost £1,000,000, and that of the exports nearly as much. Pop. (1887), with two neighbouring villages, 15,293. La Guaira is often referred to in Kingsley's *Westward Ho!*

Gualeguay, a town of Entre Rios, Argentine Republic, on the Gualeguay River, which flows into a tributary of the Paraná: there is a railway (7 miles) to Puerto Ruiz at its mouth. The town has a tannery, steam-mills, and large slaughter-houses and beef-salting establishments. Pop. 11,000.

Gualeguaychú, a town of Entre Rios, Argentine Republic, on the Gualeguaychú River, which enters the Uruguay 11 miles below. Besides slaughtering and salting works, it has an extract-of-beef factory. Pop. 14,000.

Guan, or YACOU (*Penelope*), a genus of large game birds (Gallinæ) of the family Cracidæ,

Guan (*Penelope cristata*).

among the representatives in the New World of the grouse and pheasants in the Old. It is represented by fourteen species distributed from southern Texas through Mexico to Paraguay. The guans are graceful birds, with long tails, handsome, variegated plumage, bare, dilatable patches of skin on the throat, and naked spaces round the eyes. They live mostly on trees, descending to the ground in search of their food, which consists of fruits, berries, and insects. They are remarkable for their loud, frequent cries, from which the Spaniards call them squalling pheasants. Their flesh is much esteemed, and they fall a constant and easy prey to the hunter.

Guanabacóa, a town of Cuba, lying in a small fertile plain among rocky hills, 5 miles E. of Havana. It has two barracks and a military hospital. The population is officially returned at nearly 30,000.

Guanaco. See HUANACO.

Guanajuato, an inland state of Mexico, with an area of 12,500 sq. m., and a pop. in 1893 of 1,007,116. The greater part of the surface belongs to the lofty plateau of Anahuac (q.v.), and is traversed by the Sierra de Gorda in the north, and the Sierra de Guanajuato (11,030 feet) in the centre; the south-west portion belongs to the fertile plain of Bajio. The riches of Guanajuato consist chiefly in its valuable mineral products; there are large numbers of gold, silver, lead, copper, and quicksilver mines still worked. Stock-raising is of some importance, but agriculture is little pursued, although the soil yields most products of both the temperate and tropical zones; a noteworthy article of export is chillies (see CAPSICUM). Large cotton and woollen factories have been established by foreigners.—GUANAJUATO, the capital, is curiously situated on both sides of a deep ravine, traversed by a mountain-stream that in the rainy season is swelled to a foaming torrent. The streets are steep and tortuous, the houses frequently of four or even five stories. The public buildings include a large government palace, a mint, barracks, a cathedral, several convents and colleges, an art-school, and the Alhondiga, a public granary. The electric light and telephones have been introduced. Surrounded by a district honeycombed with mines, Guanajuato presents mainly the appearance of a mining-town; its handsomest private houses belong to the wealthy proprietors of mines, and it contains several amalgamation works, others lining the cañon for several miles. There

are also blanket factories and cotton-printing works. Pop. 52,112.

Guanare, capital of the state of Zamora, in Venezuela, stands on a river of the same name, and has a pop. of 10,390.

Guanches, the aborigines of the Canary Islands (q.v.).

Guanin is a yellowish-white, amorphous substance, which derives its name from its being a constituent of guano; but it also forms the chief constituent of the excrement of spiders, has been found attached to the scales of fishes—the bleak, for example—and seems to be a normal constituent of the mammalian liver and pancreas. With regard to its occurrence in guano, as it has not been found in the recent excrement of sea-birds, there is every reason to believe that it is formed by slow oxidation (from atmospheric action) of the uric acid, much as uric acid can be made to yield urea and oxalic acid. And in the pancreas and liver it probably represents one of those transitory stages of disintegrated nitrogenous tissue which are finally excreted by the kidneys in the more highly oxidised form of urea. Guanin is a diacid base, but also forms salts with metals, and combines with salts. When heated with hydrochloric acid and potassium chlorate, it is oxidised to carbon dioxide, guanidin, and parabanic acid.

Guano (derived from the Peruvian word *huano*, 'dung') is the excrementitious deposit of certain sea-fowl, which was found in immense quantities on certain coasts and islands where the climate is dry and free from rain. Although the use of guano as a manure is comparatively recent in Britain and in Europe, its value in agriculture was well known to the Peruvians long before the coming of the Spaniards. Alexander von Humboldt first brought specimens of guano to Europe in 1804, and sent them to Fourcroy, Vauquelin, and Klaproth, the best analytical chemists of the day.

The commercial value of guano depends almost entirely upon the amount of decomposition to which it has been subjected by the action of the atmosphere, the value consisting as it does essentially of nitrogenous and phosphatic compounds, the former being chiefly ammonia salts derived from the decomposition of the uric acid and urates which exist in the fresh excrement. The ammoniacal portion of these deposits, and some of the phosphates, are tolerably soluble in water, and are readily washed away by rain. There are three classes of guanos: (1) those which have suffered little by atmospheric action, and which retain nearly the whole of their original constituents, such as the Angamos and Peruvian guanos; (2) those which have lost a considerable portion of their soluble constituents, but remain rich in their less soluble constituents—the phosphates of lime and magnesia, such as the Ichaboe, Bolivian, and Chilian guanos; (3) those which have lost nearly all their ammonia, and contain but little more than the earthy phosphates of the animal deposit—many being further largely contaminated with sand. In the last class must be placed the various African guanos (excepting that from Ichaboe), West Indian guano, Kuria Muria (islands off the coast of Arabia) guano, Sombrero guano, Patagonian guano, Shark's Bay guano (from Australia), &c.

Most of the so-called Peruvian guano has been obtained from the Chincha Islands off the coast of Peru. The following table represents the mean of 78 samples of Peruvian guanos:

Moisture	13·67
Organic matter and salts of ammonia	52·05
Earthy phosphates	22·78
Alkaline salts containing 3·34 phosphoric acid, and equal to 6·89 soluble phosphate of lime	9·67
Sand, &c.	1·83
	100·00
Ammonia per cent.	16·52

The following table gives the mean of several analyses of the inferior kinds of guano, the first four belonging to the second class and the remaining three to the third class:

	Ichaboe (older deposits)	Ichaboe (later deposits)	Chilian.	Bolivian.	Patagonian.	Kuria Muria.	Saldanha Bay
Moisture	27·3	20·0	20·4	10·1	25·0	18·1	20·0
Organic matters and salts of ammonia	34·3	24·4	18·6	21·6	18·3	12·4	14·9
Earthy phosphates	30·3	20·4	31·0	51·5	44·0	42·7	56·4
Alkaline salts	5·0	6·2	7·3	14·1	2·1	4·2	5·8
Carbonate of lime						4·1	
Sand, &c.	3·1	29·0	22·7	2·7	10·6	18·5	2·9
	100·0	100·0	100·0	100·0	100·0	100·0	100·0
Ammonia, per cent.	7·3	6·0	5·47	4·5	2·5	2·05	1·47

The nitrogen in these analyses is calculated as ammonia for the purpose of comparison. In reality it exists in various forms of combination—viz. as uric acid, urea occasionally, urate, oxalate, hydrochlorate, phosphate, &c., of ammonia, other urates, Guanin (q.v.), and undefined nitrogenous compounds. Hence, as may be inferred, a complete analysis of guano is a work of very considerable labour; but, as its agricultural value depends mainly on the quantities of ammonia, soluble and insoluble phosphates, and alkaline salts which it contains, such analyses as those we have given are sufficient for practical purposes, and they are easily made.

If the value of a manure be calculated, as is done by Boussingault and other chemists, according to the amount of nitrogen which it contains, one ton of good Peruvian guano is equal to 33⅓ tons of farmyard manure, 20 tons of horse-dung, 38½ tons of cow-dung, 22½ tons of pig-dung, or 14½ tons of human excrement.

The introduction of guano into Britain as a manure is comparatively recent. In 1840 only 20 casks of it were imported. In 1841 Lord Derby spoke strongly in its recommendation at a meeting of the Agricultural Society; and from that time it came rapidly into use. In 1850 the import was 116,925 tons; in 1870, 280,311 tons; but in 1880 it had fallen to 80,497 tons; and from 1885 to 1888 it had still further decreased from 25,000 to 17,000 tons. Its value as a fertiliser has been so much appreciated, and its use so extensive, that it is gradually going out of the market owing to the diminution of supplies, its place being taken by various artificial substitutes (see MANURE). See J. C. Nesbit's pamphlet, *History and Properties of Natural Guanos* (new ed. 1860).

FISH-GUANO. The organic fertiliser commonly known as Fish-guano may be shortly defined as fish dried and ground to powder. The value of fish as a fertiliser is universally admitted, and is evidenced by the eagerness shown by farmers, who reside in districts where fish can be easily and cheaply obtained, in acquiring and applying it to their land. Mussels, five-fingers or starfish, herrings, and particularly sprats may be instanced as the fish most generally used in this way. The inconvenience and expense arising from this mode

of application to the soil, on account of the bulky as well as the unpleasant nature of the material, is obvious, the non fertilising moisture alone amounting to between 60 and 80 per cent., and by so much enhancing the cost of general haulage. The desirability of converting raw fish into a concentrated and portable powder comparatively free from moisture was first practically realised only shortly before 1862 by M. Rohart, whose product was obtained from the refuse of the Norwegian cod fisheries by drying the heads and backbones of the codfish upon heated floors after they had been sun-dried on the rocks, and subsequently grinding them between millstones to a floury powder.

Of late years fish-guano has grown rapidly in favour among agriculturists, a preference based doubtless upon its merits as a fertiliser, and probably also due to its similarity both as regards origin, analysis, and effect to Peruvian guano. The supplies of Peruvian guano, as is now generally known, are practically exhausted, the imports into the United Kingdom having fallen from about 300,000 tons per annum in years gone by to about 17,000 tons in 1888. Not only in quantity is Peruvian guano deteriorating, but also in quality, the ammonia, for example, found by Voelcker in 1864 being 18·62, whereas in 1889 the very best shows only 9·50, and others vary from 6·50 per cent. down to as low as 3 per cent.

In some quarters nitrate of soda has been named as the probable substitute for Peruvian guano; but, although its supplies are at present enormous, the character, composition, and action upon the soil are entirely different, one being of a mineral and the other of an organic origin. Fish-guano may be held to contain the fish with its natural properties of nitrogen and phosphoric acid in full; while Peruvian guano, which is the accumulation during ages of the excrement of birds whose main food has been fish, must have suffered by the action upon the fish of the digestive organs of the birds, as well as the effect of the weather upon the deposits. Fish-guano may therefore be considered as the best substitute for the failing supplies of Peruvian guano. Another advantage is the fact that the available supplies of fish in Norway, Canada, Newfoundland, and elsewhere are practically inexhaustible. Fish guano, according to the fish from which it is made, analyses from 9 to 14 per cent. of ammonia, and from 13 to 32 per cent. of phosphate of lime. At the present time the selling price per ton is fixed, as regards the ammonia it contains, by the ruling market price per unit of that ingredient in nitrate of soda, and, as regards the phosphate of lime, by the price of bone and Calcutta bone-meal. The market value of fish-guano varies, according to the analyses, from about £6 to £8 per ton weight. One ton of fish-guano is said to be equal in chemical effect to seventeen times its weight in farmyard manure.

Of the most generally known fish-guano there may be said to be four kinds. There is the 'raw' guano made in Christiansund and the Lofodens, upon M. Rohart's principle, which is used principally in Germany. There is also a guano made in London, Hull, and elsewhere, from fish which has been condemned by the authorities as unfit for human food. This description, naturally, embraces fish of all kinds and sizes, its great drawback being the large quantity of oil left in the guano, the presence of which element is prejudicial to any fertiliser. By far the largest quantity of fish-guano is manufactured in various parts of Norway, but principally at Brettesnoes, in the Lofodens, by Jensen & Co., who make as much as 5000 tons per annum. This guano is made from the heads and backs of the codfish, and also from the herring. In both instances the 'raw stuff' is artificially dried and ground, much time being saved by this process, instead of waiting some months until the bones were sufficiently dried by the sun. To make 1000 tons of cod-guano 7,000,000 heads are necessary, and to obtain these 50,000 tons weight of fish have to be caught. The oil found in this guano is practically nil. The 'herring-guano' is obtained by extracting the oil and moisture by means of pressure from the herrings; the 'cake' thus obtained is then ground in the ordinary way by means of disintegrators, the result being a fine powder of high manurial value. Guano obtained from the cod analyses about 10 per cent. of ammonia and 30 per cent. phosphates, the latter high figure being due to the large predominance of bone over fleshy or nitrogenous matter. The contrary is the case in the herring-guano, in which the fleshy matter is very much greater than the bony substance, the analysis being about 13 per cent. each of ammonia and phosphate. Guano is also made in Canada and elsewhere from lobster and crab shells, and this is stated to be a valuable manure for garden purposes. The annual production of fish-guano is estimated at the present time at 15,000 tons, including that made in England, Scotland, Norway, Sweden, Newfoundland, Nova Scotia, and the United States of America. For Rock-guano, see APATITE.

Guaporé, a navigable river of South America, rises in Brazil, and for some distance forms the boundary between Bolivia and Brazil. It unites with the Mamore to form the Madeira (q.v.).

Guarana, from the seeds of a plant belonging to the genus Paullinia (natural order Sapindaceæ), from whose seeds *Guarana Bread*, a kind of food, is prepared by the Guaranis and other savages of Brazil. *P. sorbilis* is the species which yields the paste called Guarana bread. It is made in round or oblong cakes, which are regarded in all parts of Brazil as very efficacious in the cure of many disorders, and which contain, besides other substances, some of them nutritious, a considerable quantity of a substance supposed to be identical with theine or caffeine. It has been used medically in the United States and Europe. The Brazilians pound the Guarana bread, sometimes called 'Brazilian cocoa,' in water, sweeten it, and use it as a stomachic and febrifuge. It is also reputed aphrodisiac.—The genus Paullinia contains several species remarkable for their extremely poisonous properties. In the bark, leaves, and fruit of *P. pinnata* abounds a principle which slowly but surely causes death, and is employed for that purpose by the Brazilians; the dangerous Lechequana honey is obtained from *P. australis;* and from *P. cupana*, a native of the banks of the Orinoco, an intoxicating drink is procured.

Guarantee Associations, joint-stock companies on the insurance principle, which become security for the integrity of cashiers, travellers, and other employees, on payment of an annual sum calculated either upon the salary or upon the amount for which the association holds itself liable. The advantage of the system is that it obviates the necessity of requesting private friends to become sureties. See GUARANTY, and CAUTION.

Guaranty, or GUARANTEE, is a contract by which one person binds himself to pay a debt or do some act in case of the failure of some other person, whose debt or duty it is, to do the thing guaranteed. The person so binding himself is generally called the surety in England, while the person who is primarily liable is called the principal. Thus, where A borrows money, and B joins as a party in a bill of exchange or a bond to secure the loan, B is a surety. Where B guarantees that certain goods which are supplied to A shall be paid for, he is

more usually styled a guarantor than a surety, but the liability is the same.

Such a contract must be in writing, for the Statute of Frauds (29 Charles II. chap. 3) required that no action should be brought whereby to charge the defendant upon any special promise to answer for the debt, default, or miscarriage of another person, unless the agreement or some memorandum or note thereof should be in writing and signed by the party to be charged therewith, or some other person by him lawfully authorised. So that a surety can only be bound by some writing signed by himself or his agent. And Lord Tenterden's Act (9 Geo. IV. chap. 14, sect. 6) enacted the same thing as to persons making representations as to the character, ability, or dealings of another, with intent that the latter may obtain credit. In order to bind the surety, there must also be no deceit or misrepresentation used as to the nature of the risk or as to the state of the accounts. If a guaranty is given to a firm, it is not binding after a change in the firm, unless the parties expressly stipulate to the contrary. If the creditor discharges the principal, or even gives time, by way of indulgence to him, the surety is released, for he is thereby put to a disadvantage. In general, the creditor can sue either the principal or the surety for the debt at his option. If the surety is obliged to pay the debt of his principal, he can sue the principal for the money so paid, and is entitled to have all the securities assigned to him, so as to enable him to do so more effectually. If one of two or more sureties is made liable for the whole debt, he may call upon his co-sureties to contribute equally with himself. For the Scotch law, see CAUTION.

Guardafui, CAPE, the most eastern point of the African continent, and the extremity of an immense promontory (the Somali country) stretching seaward in an east-north-east direction, and washed on the north-west by the Gulf of Aden and on the south-east by the Indian Ocean. The cape is in 11° 50′ N. lat. and 51° 14′ E. long.

Guardian, in English law, is the legal representative and custodier of infants—i.e. persons under the age of twenty-one. The feudal law of guardianship was very elaborate; but its provisions have not been of practical importance since the abolition of the Court of Wards in 1641. Under the modern law, a father may, by deed or will, appoint guardians for his child. Parents themselves are called guardians by nature or for nurture; a father has the custody and control of his children, at least until they attain the age of fourteen; and this right passes at his death to the mother, either alone or jointly with any guardian whom he may have appointed. The courts appoint guardians when necessary; thus a guardian *ad litem* is appointed to defend an action brought against an infant; and if an infant is made executor a guardian is appointed to administer during his minority. If the infant is old enough to do so, he is sometimes permitted to choose his guardian. A guardian is in a fiduciary position, and his powers are usually exercised under control of the court. For his powers in regard to the infant's marriage, see INFANT.

The guardian of a lunatic is usually called a committee. In Scotland the word 'guardian' is sometimes used in reference to lunatics, but seldom applied, except in a popular sense, to those who have the custody and care of children. In corresponding cases in Scotland the custody of a child under twelve, if female, or fourteen, if male, belongs to her or his tutor; and from those ages to twenty-one the child has no legal guardian, being *sui juris*, but the care of the child's property belongs to a Curator. For guardians of the poor, see POOR LAWS.

Guardian Angels. See ANGEL.

Guards are in all armies the élite of the troops, and form the sovereign's bodyguard. In the British service the Guards compose what is called the Household Brigade, and include the 1st and 2d Life Guards, the Royal Horse Guards (see CUIRASSIERS), the Grenadier Guards (three battalions), Coldstream Guards (two battalions), and Scots Guards, formerly Scots Fusiliers (two battalions), or about 1300 cavalry and 6000 infantry. Before the abolition of purchase, the officers of the Foot Guards held higher army rank than that they bore regimentally—i.e. ensigns ranked with lieutenants of other regiments, lieutenants with captains, captains with lieutenant-colonels; and by exchanging into the line they were enabled to take rank above officers of much longer service. When purchase was abolished in 1871, it was decided that officers joining the Guards after that date should not hold this exceptional rank. The brilliant services of the French Guard in the Napoleonic wars are well known. See also the articles NATIONAL GUARD, SCOTS GUARDS, SWISS GUARDS.

Guardship is a term used in two senses. In the first place it is applied to a guardship of reserve, which is practically a depôt ship for men employed in vessels of the royal navy out of commission; and of these there are only three, stationed at Sheerness, Portsmouth, and Plymouth. In the second place the term is applied to vessels of the royal navy which are stationed at other ports on the coast; they are the headquarters of the different coastguard districts, and are kept manned with reduced crews; they can complete their crews at any time from the men in the coastguard, and so manned can proceed to sea at once as a fighting squadron, and, indeed, are supposed to be in the English Channel ready for action in four days after a mobilisation order is issued. The Royal Naval Reserve in some cases do their drill on board these ships, which, however, are in no sense guard (i.e. defence) ships for the particular ports at which they are stationed.

Guarea, a genus of tropical American trees of the natural order Meliaceæ, of some of which the bark is used as an emetic and purgative. *G. grandifolia* is called Musk-wood in some of the islands of the West Indies, the bark smelling so strongly of musk that it may be used as a perfume. Although the tree attains timber size and has been employed for making rum hogsheads when other material was scarce, the wood contains a bitter resinous substance, the flavour and smell of which is communicated to the spirits to their detriment.

Guarini, GIOVANNI BATTISTA, poet, was born at Ferrara, 10th December 1538, studied at Pisa, Padua, and Ferrara, and was appointed to a chair at Ferrara. At the age of thirty he accepted service at the court of Ferrara, and was entrusted by Duke Alfonso II. with various diplomatic missions to the pope, the emperor, Venice, and Poland. He died in 1612 at Venice. As a poet, he is remarkable for refined grace of language and sweetness of sentiment, while his defects are occasional artificiality, a too constant recurrence of antithetical imagery, and an affected dallying with his ideas. His chief and most popular work, *Il Pastor Fido* ('The Faithful Swain'), obtained a high measure of popularity on its appearance, and passed through forty editions in the author's lifetime, though it is really an imitation of Tasso's *Aminta*. An incomplete) edition of Guarini's varied writings, including sonnets, comedies, satires, and political treatises, was published at Verona in 1737 (4 vols.). See the monograph by Rossi (Turin, 1886).

Guarino (Lat. *Varinus*), a learned Italian, born at Verona in 1370, went to Constantinople in

1388 to learn Greek under Chrysoloras. After his return, he taught in Verona, Padua, and Bologna, was called to Prince Lionello of Ferrara, acted as interpreter at the Council of Ferrara, and died in 1460. He performed great services for the revival of classical studies; wrote Greek and Latin grammars; translated parts of Strabo and Plutarch; and helped to establish the text of Livy, Pomponius Mela, and Pliny. See monographs by Rosmini (1806) and Sabbadini (1885).

Guarnieri, or GUARNERI, the name of one of the three celebrated families of violin-makers who flourished at Cremona in the 17th and 18th centuries. The most notable of the family were ANDREA (fl. 1650–95), a pupil of Niccolo Amati, and his sons GIUSEPPE (fl. 1690–1730) and PIETRO (fl. 1690–1725); and his nephew GIUSEPPE, commonly called Giuseppe del Gesù, who flourished 1725–45, and whose violins were not inferior to those of the Stradivari.

Guastalla, a small town of Italy, on the Po, 19 miles by rail NE. of Parma. The seat of a bishop (since 1828), it has an old castle, and a school of music. Guastalla gave name in 1406 to a countship, in 1621 to a duchy. Pop. 2648.

Guatemala, a republic of Central America, lying between 13° 46′ and 17° 44′ N. lat., and bounded on the W. and N. by Mexico; on the E. by Belize, the Gulf of Honduras, and the republic of Honduras; on the S. and W. by San Salvador and the Pacific. Part of the frontier, however, is not yet fixed, the boundary line towards Yucatan in particular being still undetermined. In the absence of government surveys the area is estimated at some 46,600 sq. m., much of which is wholly unexplored, so that the course of even the larger rivers and the direction of the main mountain chains, as laid down in the maps of the country, are to a considerable extent hypothetical. The greater part of Guatemala is mountainous, the highlands having a mean elevation of about 7000 feet above the sea; but the surface presents great variety, with extensive plateaus, terraces, and upland valleys—the last notable for their beauty, fertility, and favourable climate. The main chain runs generally parallel with the Pacific coast, which it approaches within fifty miles; on this side the slope is steep and broken by many volcanoes, while towards the Atlantic it sinks in gentle incline, with subsidiary ranges extending to the water's edge. Of the volcanoes several are active; the most noted is Fuego (12,075 feet), which lays claim to nearly half of the recorded eruptions in Central America. Agua, from whose crater-lake a deluge of water destroyed the first capital in 1541, has been extinct for centuries. Earthquakes are frequent, and occasionally (as in 1863 and 1874) very severe; sulphur and other hot springs are numerous. Guatemala is well watered, the principal rivers being the Usumacinta, which flows into Campeachy Bay, and the Polochic and Motagua (about 280 miles), which fall into the Gulf of Honduras; yet, owing to the conformation of the country, water in many parts is scarce in the dry season. Those of the streams, moreover, that are navigable possess the ever-present bar common to Central American rivers. The lakes include the Lago de Izabal (36 miles long), below which the Polochic becomes the Rio Dulce; the Laguna del Peten (27 miles by 15); and the Lagos de Atitlan (17 by 8) and Amatitlan (9 by 3).

The climate, except in the low-lying districts, may be described as perpetual spring, and is generally healthy, but the people are for the most part utterly regardless of all sanitary laws. The hot coast-lands on the Pacific are especially liable to visitations of yellow fever. At the capital the temperature ranges from 40° to 87° F., and the annual rainfall is about 53 inches; in the lowlands the mean range is from 70° to 90°; in the uplands ice appears in the dry winters. The rainy season extends generally from April to October, April and May being the hottest months.

Guatemala is as yet of little importance as a mining country, but chiefly because its resources are almost wholly undeveloped. Gold, which is found in most of the river beds, is worked to some extent in the department of Izabal; some silver-mines are also worked, and a mint was established in 1888; and salt and saltpetre are mined, though not in large quantities. Other minerals are lead, iron, copper, coal, quicksilver, marble, porphyry, sulphur, zinc, gypsum, &c. But the wealth of the country consists in its rich soil, which, according to the altitude, yields the products of every zone. The shores are lined with mangroves, the rivers with bamboos, beyond which rise the forests, where the mahogany, the cocoa-nut, cohune, and other palms tower above the wild bananas, ferns, and gingers that scantily cover the bare soil below, whilst the exuberance of orchids and trailing parasites confuses the identity of the trees. In the uplands are forests of huge pines and spruces and oaks, agaves and cherimoyas appear on the hillside, and thick grass clothes the ground; even in the dry lava plains a coarse grass springs up between the lava blocks, and acacias and calabash trees are met with. The forests contain over a hundred kinds of timber trees, including many of the most valuable; yet, owing to the absence of roads and means of transport, Guatemala is obliged to import a large quantity of Californian red-wood and other timber. In 1888 the appointment of keepers of the national forests was ordered. Maize and haricot beans (frijoles) grow freely everywhere, peas and potatoes in sufficient quantity for consumption, wheat in the uplands, and rice in the bottom-lands. Other products are coffee (the chief export), sugar, cacao, india-rubber, tobacco, cotton, pita and sisal hemp, sarsaparilla, and many medicinal plants, bananas, and a number of other fruits, mostly of the finest quality. The export of cochineal, formerly of chief importance, has almost ceased. Cattle are raised sufficient for the needs of the country, though not, as in Honduras, for exportation. The fauna of Guatemala includes the jaguar, puma, ocelot, coyote, red-deer, tapir, peccary, armadillo, and several monkeys; iguanas and turtles are numerous, whereas the alligators are small and not frequent, and boas and venomous snakes, though the number of species is considerable, are seldom met with. The birds are of great variety and beauty, comprising several hundred species; the national emblem is the superbly coloured Quetzal (q.v.). Insects abound, the most notable being the brilliant butterflies, immense beetles, locusts, many kinds of ants, scorpions, tarantulas, grasshoppers, mosquitoes, flies, and jiggers.

The industries of Guatemala are chiefly confined to the manufacture of woven fabrics, pottery, and saddlery; there are several chocolate factories, and flour and saw mills in the country, and numerous distilleries of the fiery *aguardiente*, the sale of which is a government monopoly, yielding about a fourth of the annual revenue. San José, the chief port, Champerico, and Ocos, all on the Pacific, are merely open roadsteads, provided with iron piers; but Santo Tomás, on the Atlantic side, has a good harbour; and in 1883 Livingston, at the mouth of the Rio Dulce, was proclaimed a free port for ten years, since when the trade has considerably increased. The development of the country, however, is greatly hampered by the absence of serviceable roads, which are for the most part represented

by rough mule-tracks. For the five years ending 1894, the average annual imports amounted to about 7,000,000 dollars, the average annual exports to about 15,000,000 dollars. The imports, of which Britain supplies nearly a third and the United States a sixth, are chiefly specie, cotton, woollen, and silk goods, wines and spirits, railway plant, and flour; the principal exports are coffee, sugar, fruits, and hides.

About a third of the people are said to be of European descent, and the rest aborigines (Maya-Quichés); but this rough division takes no account of the mixed races, which embrace nearly a score of distinct crosses recognised by separate names; these Ladinos greatly outnumber the comparatively few pure descendants of the Spanish invaders or settlers. The Indians of the northern forest-country are wild and uncivilised. A census taken in 1880 returned the population at 1,224,602; that of 1890 recorded a total of 1,460,017. The capital, Guatemala la Nueva, in 1895 had 85,000 inhabitants, Quetzaltenango 20,000, Chimaltenango and Antigua Guatemala about 14,000. The state religion is the Roman Catholic, which is practically the only form in use, although others are allowed by the constitution. But many of the fine old churches of the country are crumbling to ruin; and it is said that scarcely a tenth of the population ever enter those that remain in use. About a fourth of the births are illegitimate, the larger proportion occurring among the whites. Since 1879 primary education has been compulsory and gratuitous. There are now about a thousand primary schools of all kinds, attended by some 50,000 pupils; excellent high schools for boys are found in the capital, Quetzaltenango, and Chiquimula, and for girls in the capital and at Belen; and schools of law, medicine, engineering, philosophy, literature, and music are also provided.

Guatemala is divided into twenty-two departments, under civil governors. The executive is vested in a president, elected for six years by direct popular vote; he appoints six secretaries of state, who with nine others form the council. The assembly is elected by universal suffrage, to the number of one for every 20,000 of the population. The standing army consists nominally of about 2500 men, the militia of nearly 65,000. This force is a heavy drain on the resources of the country, whose finances are not in a flourishing condition. Calculated at the average rate of 6½ dollars per pound sterling, the revenue is about £1,000,000, but the expenditure generally exceeds the revenue. In 1895 the internal debt was returned (on the same calculation) at £964,000, the floating debt at £400,000, and the foreign debt at £890,000—making a total of near £2,500,000, including past interest. To meet the increase in the floating debt, which has grown up since 1887, large quantities of paper money have been put in circulation. But on the whole it must be said that of late the interest on both the internal and the foreign debt has been punctually paid, and the bonds have risen greatly in value.

Guatemala was conquered in 1524 by Cortez' lieutenant, Alvarado, with every accompaniment of cruelty and oppression. After three centuries of harsh and greedy rule, under which the viceroyalty of Guatemala embraced all that is now known as Central America, independence was proclaimed, 15th September 1821. A confederation survived with difficulty from 1824 to 1839: it fell before the attacks of Rafael Carrera, an uneducated Indian of low birth, who founded the present republic, and *reigned* over it until his death in 1865. From 1871 until he was killed in a war with Salvador in 1885, General Barrios was president, and under his iron rule the country made considerable progress; monastic orders were rigorously suppressed, and much of the church property was confiscated and appropriated to the uses of public education and for other purposes. There are at present only two short lines of railway (150 miles) in operation: a line from Puerto Barrios, on the Atlantic, to Guatemala city, to connect the Atlantic with the Pacific, was commenced in 1884, but in the meantime has been abandoned. There are in the republic 180 post-offices, and 2500 miles of telegraph.

The best work on Guatemala is Brigham's *Guatemala, the Land of the Quetzal* (1887). See also Stephens, *Incidents of Travel in Central America* (New York, 1841); Dollfus and Montserrat, *Voyage archéologique dans les Républiques de Guatemala et de San Salvador* (Paris, 1868); Boddam Whetham, *Across Central America* (Lond. 1877); Laferrière, *De Paris à Guatemala* (Paris, 1877); a paper by Mr A. P. Maudslay in *Proc. Roy. Geog. Soc.* (1883); Charnay, *Les Anciennes Villes du Nouveau Monde* (Paris, 1885); Stoll, *Zur Ethnographie der Republik Guatemala* (Zurich, 1884), and *Guatemala, Reisen und Schilderungen* (Leip. 1886); a very full report by Consul-general Hayes Sadler, in No. 600 of 'Diplomatic and Consular Reports' (1889); for the geography, Lemaire, *Guia geográfica* (Guatemala, 1881); and for the early history, Milla y Vidaurre, *Historia de la América Central* (Guatemala, 2 vols. 1879).

Guatemala (*Santiago de Guatemala*; also *Guatemala la Nueva*), capital of the republic of Guatemala, and the largest and most important city of Central America, stands on a wide plateau, nearly 4900 feet above sea-level, and 72 miles by rail NNE. of its port, San José. It is regularly built, with wide, roughly-paved streets running at right angles, and houses nearly all of one story; the extensive suburbs are inhabited chiefly by Indians. In the plaza the metropolitan cathedral towers above the government buildings, which include the large, one-story residence of the president. There are numerous other churches, several large hospitals, and the archbishop's palace. Education is cared for in the Instituto Nacional, with laboratories, a museum, a zoological garden, and a good meteorological observatory; and in well-appointed schools of arts and design, agricultural and business colleges, normal schools, a polytechnic institute, and schools of law and medicine—all supported by government. Other public structures are two large general markets, a subsidised theatre, and a bull-ring. Tramways and the electric light have been introduced, and there are a score of public fountains and washing-places; but the water, brought 6 miles by an aqueduct, is not good. There are some manufactures and a considerable commerce, all the foreign trade of the republic being concentrated here. Pop. (1895) 85,000.—The present city of Guatemala is the third capital of that name. The first, now called *Ciudad Viejo*, lies on the plain between Fuego and Agua. It was founded by Alvarado in 1524, and destroyed in 1541 (see GUATEMALA). It has a population now of some 3000 Indians. The second capital, *Guatemala la Antigua* (Old Guatemala), 2½ miles NE. of the first and 21 miles WSW. of the present capital, was one of the finest cities of America, with a hundred churches and 60,000 inhabitants; in 1773 it was for the second time destroyed by an earthquake, but among the noble ruins a new city has arisen, lit also with the electric light, and sheltering a population of at least 14,000.

Guava (*Psidium*), a genus of trees and shrubs of the natural order Myrtaceæ, mostly natives of tropical America, and some of them yielding fine and much-valued fruits. They have opposite entire, or almost entire leaves, a 3–5-lobed calyx, 4–5 petals, and a 1–5-celled berry with many-seeded cells.—The Common Guava or White Guava (*P.*

pyriferum) is a low tree of 7–20 feet, with numerous branches, obtuse smooth leaves 2–3 inches long, and fragrant white flowers on solitary axillary stalks. It is said to be a native alike of the East and West Indies, and is now much cultivated in both. It is not improbable, however, that it was introduced into the East Indies from America, but it has now become fully naturalised; it is to be seen in the jungle around every cottage in Ceylon. It has long been occasionally grown as a stove plant in Britain. The fruit is larger than a hen's egg, roundish or pear-shaped, smooth, yellow; the rind thin and brittle; the pulp firm, full of bony seeds, aromatic, and sweet. The jelly or preserve made from it is highly esteemed, and is now regularly imported into Britain from the West Indies and South America. The rind is stewed with milk, and is also made into marmalade. This fruit is rather astringent than laxative. Guava buds, boiled with barley and liquorice, make a useful astringent drink in diarrhœa.—The Red Guava (*P. pomiferum*), also now common in the East as well as in the West Indies, produces a beautiful fruit, with red flesh, but not nearly so agreeable as the white guava. It is very acid.—The China Guava (*P. Cattleianum*), a native of China, produces fruit readily in vineries in Britain. It is a larger tree than the white guava. The fruit is round, about the size of a walnut, of a fine claret colour when ripe, growing in the axils of the leaves; the pulp purplish-red next the skin, becoming paler towards the centre, and there white, soft, subacid, in consistence and flavour resembling the strawberry. It makes an excellent preserve. It succeeds in the open air in the south of France.—On some of the mountains of Brazil grows a dwarf species of Guava, called Marangaba (*P. pygmæum*), a shrub, 1–2 feet high, with fruit about the size of a gooseberry, much sought after on account of its delicious flavour, which resembles that of the strawberry.—The Bastard Guava of the West Indies is a species of Eugenia (q.v.).

Guava (*Psidium pyriferum*): a, section of fruit.

Guaxaca. See Oaxaca.

Guayaquil, chief commercial city of Ecuador, and capital of Guayas province, lies in the fertile valley of the Guayas, some 30 miles above its mouth. From the river the town, with its pagoda-like towers, presents an imposing appearance, which is not borne out on closer inspection, and the climate is hot and unhealthy, yellow fever being very common. Most of the houses are built of bamboo or wood and earth, and covered with creepers. The custom-house is the most noteworthy of the public buildings, which include a cathedral and a town hall. The town, however, is now lit with gas, there is a complete system of tramways, and the streets are gradually being paved; while in 1888 considerable progress was made with much-needed water works. In 1889 a statue to Bolivar was erected. The leading manufacturing establishments are combined steam sawmills, foundries, and machine-shops; there are also ice-factories and a lager beer brewery; and the place is noted for its straw hats and hammocks. Ships drawing 18 feet can come up to the breakwater, and below the town there is a wharf, with a dry-dock opposite. The railway into the interior was stopped at Chimbo (60 miles). Most of the trade is in the hands of foreigners; of 200 vessels of 150,000 tons that clear the port annually, nearly half the ships, and more than half the tonnage, are British. Annual exports average £1,300,000, of which cocoa represents nearly five-sixths; the other principal items are coffee, ivory-nuts, rubber, hides, and specie. About 7 per cent. is shipped to Britain, and 14 per cent. to the United States. The town was founded by Orellana in 1537, and removed to its present site in 1693. Pop. about 30,000. The Bay of Guayaquil is the only important bay on the west coast of South America north of Patagonia.

Guayas, a fertile coast-province of Ecuador, with an area of about 9000 sq. m., and a pop. (1895) of 98,640. Its chief product is cocoa, of a very high quality. Capital, Guayaquil.

Guaymas, a well-sheltered port of Mexico, on the Gulf of California, the terminus of the Sonora Railway (353 miles by rail S. by W. of Benson, an Arizona station on the Southern Pacific Railroad). It is a small place, excessively hot, surrounded by barren mountains, and mostly inhabited by Indian fishermen; but already it exports precious metals, wheat, flour, &c. in considerable quantities, and its trade is increasing. Pop. 5000.

Guayra. See Guaira.

Gubbins, a half-savage race in Devon, are mentioned by the pastoral poet, William Browne, in 1644, in a poem on Lydford Law, printed in Westcote's *Devon*. He says:

> This town was crossed with beastly [illegible],
> But [illegible] [illegible] [illegible]

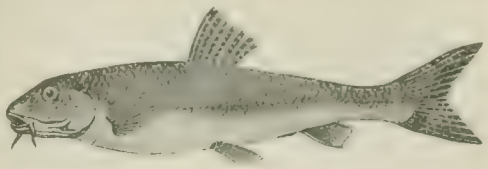
patriarch of the family died at Whitstone, having spent the decline of his days in an old cider cask. After the death of the grandmother, about 1860, the family got into difficulties of one sort or another, and were dispersed.

Gubbio (anc. *Iguvium* or *Eugubium*), a city of central Italy, on the south-western declivity of the Apennines, 20 miles NNE. of Perugia. It has a 13th century cathedral, several medieval palaces—the Brancaleoni with a valuable picture-gallery—and remains of an ancient theatre. The celebrated Engubine Tables (q.v.) are preserved in the town-house. Gubbio was noted for its majolica ware, which was brought to perfection by Giorgio Andreoli in 1517–37, by his delicate use of a beautiful ruby lustre. Two celebrated yellow lustres were also used on Gubbio majolica. A few factories still imitate the medieval fayence. From a town of 30,000 inhabitants, it has dwindled to 5540 since its incorporation in the duchy of Urbino in 1384.

Guben, a manufacturing town and river-port of Prussia, in the province of Brandenburg, at the head of the navigable portion of the Neisse, 28 miles S. of Frankfort-on-the-Oder. The principal staples are hats and cloth. There are also wool spinning, tanning, machine factories, &c. The town was destroyed by the Hussites in 1434 and 1437, and was twice occupied by the Swedes during the Thirty Years' War. Pop. (1875) 23,738; (1885) 27,086; (1890) 29,328.

Gubernatis, Angelo de, an eminent Italian orientalist and busy *littérateur*, who was born at Turin, April 7, 1840. He studied at the university there, and afterwards at Berlin under Bopp and Weber; and was appointed extra-ordinary professor of Sanskrit at Florence in 1863, and ordinary professor in 1869. Becoming attracted by the wild socialistic dreams of Bakunin, he left his chair in order to be more free, and married Bakunin's niece; but a closer acquaintance with subversive socialism soon restored him to his reason. He became a candidate anew for his chair, and after some not unnatural hesitation was re-elected. His earliest works were mostly contributions to Sanskrit scholarship, alternating with incessant contributions to his own and to others' journals. He made his reputation European by his *Zoological Mythology* (Lond. 1872), a work hopelessly marred by rashness in speculation, but yet serviceable; *Storia comparata degli usi Natalizi* (1872), *Storia comparata degli usi Funebri* (1873), *Mitologia Vedica* (1875), *Storia dei Viaggiatori Italiani nelle Indie orientali* (1875), *Mythologie des Plantes* (Paris, 1878), *Lettere sopra l'Archæologia Indiana* (1881), and *Lettere sopra la Mitologia comparata* (1881). In the region of biography and literary history he has published *Ricordi biographici* (1873), the great *Dizionario biografico degli Scrittori contemporanei* (1879–80); monographs upon Giovanni Prati, Manzoni, and others; and finally *Manuale di storia della Litteratura Indiana* (1882), and the ponderous *Storia universale della Litteratura* (15 vols. 1882–85). De Gubernatis has shown phenomenal industry and many-sidedness, and has made real contributions to learning, but he must not be taken too seriously as a mythologist. He became professor of Sanskrit at Rome in 1891.

Gudgeon (*Gobio*), a genus of small, carp-like (Cyprinoid) fishes common in the fresh waters of Europe. The dorsal fin is short, without a spine; the mouth is directed downwards, and has little barbules at the angles; the scales are of moderate size; and there are two rows of hooked pharyngeal teeth. The common gudgeon (*G. fluviatilis*), which abounds in many English rivers, especially in those that run over gravel, is a small fish rarely exceeding 8 inches in length, with upper parts olive-brown, spotted with black, and the under parts white. The gudgeons swim in shoals, and, like the barbels, feed on worms, molluscs, and other small animals.



The Common Gudgeon (*Gobio fluviatilis*).

Angling for gudgeon requires no art, so readily are the fish lured. Though small, the fish are esteemed for the table. Besides the British gudgeon, which is widely distributed on the Continent, there is only another species (*G. uranoscopus*), also European, but apparently restricted to the river-basins of the Danube and Dniester; allied genera occur in the East.

Gudrun, or Kudrun, an old German epic, built up out of the popular songs and traditions of the seafaring folk who dwelt on the shores of the North Sea between Elbe and Seine. It relates the history of three generations of the kings of the Hegelings (Frisians), and in the third part tells how Gudrun, the daughter of Hettel, king of the Hegelings, was carried off from her home by Hochmut, son of the king of Normandy, how she preferred to work like the lowest maidservant in the house of Hochmut's mother, and endure the greatest indignities, rather than break her troth pledged to Herwig, king of Zealand, and how finally she was rescued by her brother and her betrothed. This poem, which has been entitled the German *Odyssey*, as the *Nibelungenlied* is sometimes called the German *Iliad*, was written, or rather arranged and edited, by an unknown poet in Austria, in all probability in the end of the 12th century. The best editions are by Karl Bartsch (4th ed. 1880), Martin (1872), and Symons (1883); and the best translations into modern High German by Simrock (8th ed. 1873) and Weitbrecht (1884).

Guebres (from Turkish *giaour;* cf. Arab. *kafir*, 'unbeliever'), the followers of the ancient Persian religion as reformed and consolidated by Zoroaster. The name Guebres is supposed to have been first bestowed upon this sect by their Arabic conquerors in the 7th century; they are also known as Parsees (q.v.). See also Persia, Zoroaster.

Guebwiller. See Gebweiler.

Guelderland (*Geldern, Gelderland*), a province of the Netherlands, is situated between the Zuider Zee on the north-west and the Prussian dominions on the south-east. It has an area of 1957 sq. m., and a pop. (1896) of 548,748, two-thirds Protestants. It is watered chiefly by the Meuse, the Yssel, the Rhine, and the Waal. The surface is undulating, and about Arnheim, the capital, and Nimeguen are the most picturesque districts in the Netherlands. The climate is healthy, and the soil, though very unequal, is on the whole good; the southern district, Betuwe (see Batavi), is one of the most fertile tracts in Europe. Agriculture is prosecuted with great success. Wheat, rye, buckwheat, tobacco, &c. are extensively grown. Among the manufactures, beet-sugar, spirits, bricks and tiles, paper, and cotton goods are the principal. The duchy of Gueldres or Guelderland was more extensive than the modern Dutch province, stretching southwards along the Meuse to beyond Venlo. It was originally inhabited by the Batavi and Sigambri, and after

them by the Franks. In 870 it passed to Germany; and in the end of the 11th century became a territorial power, its ruler bearing the title of count. This was exchanged for the higher title of duke in 1383. These dynastic princes maintained their independence for just one century longer; in 1483 their duchy was taken possession of by Maximilian of Austria. Yet it was not until 1543 that the power of the Duke of Gueldres was finally broken and his land definitively incorporated with the Austrian Netherlands. On the revolt of the northern provinces of Holland the northern part of Gueldres threw in its lot (1579) with them, whilst the southern part remained faithful to Spain. The latter was given up to Prussia in 1713. By the peace of 1814 Gueldres was finally divided between Holland and Prussia.

Guelder Rose, a cultivated form of *Viburnum Opulus* (see VIBURNUM), also popularly named Snowball Tree. The normal or wild form of the

Fig. 1.—The Guelder Rose.

guelder rose is a pretty plentiful native of England and Ireland, but is less frequently to be found in a wild state in Scotland. It is widely distributed in Europe and Russian Asia, and even extends into the Arctic regions. Its flowers appear in early summer in rather dense cymes, 2 or 3 inches in diameter; the outer flowers become much enlarged, attaining about an inch in diameter, but, having neither stamens nor pistils, are perfectly barren. The inner flowers are small, white, with two or three pistils on very short styles, and are followed by globular, blackish-red berries. In the cultivated form the flowers are all monstrous and barren, like the outer flowers of the cymes of the wild form; and crowded as they are together in the cyme, the structure of which is not enlarged, the inflorescence assumes the form of a compact ball, hence the name Snowball Tree. In cultivation the plant attains the proportions of a small tree, and flowers most freely after it has acquired some age. When in flower in May and June it is one of the most ornamental of hardy trees, and is therefore planted largely in pleasure-grounds and shrubberies. The wild form is reared from seeds and cuttings, the monstrous form from cuttings or layers only.

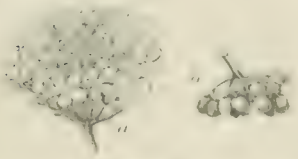


Fig. 2

Guelph, an inland port of entry in Ontario, capital of Wellington county, on the river Speed, 45 miles W. by S. of Toronto by rail. It is the seat of the Ontario Agricultural College, and has several flour-mills, woollen-mills, and manufactories of sewing-machines, &c., the Speed supplying abundant motive-power. Pop. (1891) 10,537.

Guelphic Order, an order of knighthood for Hanover, instituted by George IV., when Prince Regent, in 1815. It is both a military and civil order, and is unlimited in number. See ORDERS.

Guelphs and Ghibellines, the names of two great parties, the conflict between which may be said almost to epitomise the history of Italy and Germany from the 11th to the 14th century. The origin of these names was formerly the subject of much speculation; but historians are now agreed in tracing them respectively to the two families, Welf and Waiblingen, which in the 12th century were at the head of two rival parties in the German empire, and whose feuds came to be identified historically with the respective principles for which these parties contended. Welf was the personal name of a prehistoric founder of the family still represented in the royal English and (dispossessed) Hanoverian houses; Waiblingen, a small town in Würtemberg, was a possession of the House of Hohenstaufen. The assumption of the names as party names is traditionally fixed at the battle of Weinsberg, in Swabia, 1140, between the Emperor Conrad of Hohenstaufen (Duke of Franconia) and Welf, uncle of Henry the Lion, Duke of Saxony, when the leaders rallied their followers by the respective war-cries, 'Hie Waiblingen!' 'Hie Welf!' It may be mentioned that Matthew Villani ingeniously gives as etymology of Ghibellini, *Guasta balia* or *guidatori di battaglie*, 'leaders in battles;' of Guelfi, *guardatori di fe*, 'defenders of the faith.'

As the chief theatre of the conflict of these parties was Italy, the original names took the Italian forms of *Ghibellini* and *Guelfi*. The former may, in general, be described as the supporters of the imperial authority in Italy, the latter as the opponents of the emperors. The opposition to imperial authority in Italy arose from two distinct parties, which, for the most part, made common cause with each other from the church, which asserted its own spiritual independence, and from the minor principalities and free cities, which fought for their provincial or municipal rights and liberties. Five great crises in the strife of the Guelph and Ghibelline parties are commonly noted by historians: under Henry IV., in 1055; under Henry the Proud of Bavaria and Saxony, in 1127; under Henry the Lion, in 1146; under Frederick Barbarossa, in 1159; and in the pontificate of the great champion of churchmanship, Innocent III. The cities of northern Italy were divided between the two parties—Florence, Bologna, Milan, Piacenza, Modena, Ravenna, and others, as a general rule, taking the side of the Guelphs; while Pisa, Lucca, and Arezzo were Ghibelline. Several important cities transferred their sympathies from the one party to the other according to the exigencies of domestic politics. The great Italian families, in like manner, took opposite sides; but the policy of each family frequently varied from one generation to another. In general, it may be said that the nobles of the more northern provinces of Italy inclined to the Ghibelline side, while those of the central and southern provinces were Guelph. By degrees, however, especially after the downfall of the preponderance of the German emperors in Italy, the contest ceased to be a strife of principles, and degenerated into a mere struggle of rival factions, who availed themselves of the prestige of ancient names and traditional or hereditary prejudices. Even in 1272 Gregory X. could with truth reproach the Italians with their sanguinary animosities for the sake of

what were but names, the meaning of which few of them could understand or explain; and, in the following century, in 1334, Benedict XII. practically disallowed altogether the reality of the grounds of division between the parties, by proscribing, under pain of the censures of the church, the further use of those once-stirring names, which had long been the rallying words of a pitiless warfare. From the 14th century we read little more of Guelphs or Ghibellines as actually existing parties; but in the sense already explained the conflict of principles which they represent is found in every period of history. See Bryce, *The Holy Roman Empire* (9th ed. 1888); Oscar Browning, *Guelphs and Ghibellines* (1893).

The reigning family of Great Britain occupy the throne in virtue of the Act of Settlement of 1701, which made Sophia, daughter of Frederick, elector Palatine, and of Elizabeth, daughter of James I. of England, heiress of the English crown. Sophia married Ernest Augustus, Duke of Hanover, the fourth son of George, Duke of Brunswick-Lüneburg, a direct descendant of the prince of Guelph blood in whose favour Frederick II. created the duchy of Brunswick-Lüneburg in 1235. See Hanover.

Guercino, 'the squint-eyed,' properly Gian-Francesco Barbieri, a painter of the Bolognese school, was born 2d February 1590, at Cento, not far from Bologna. His earliest studies in painting were made in his native town; then from 1619 to 1623 he visited different cities of Italy, particularly Rome and Venice, to improve himself in his art. In 1642 he went to live at Bologna, where he became the head of a flourishing school of painting, and there he died 22d December 1666. Guercino's early paintings show perceptible signs of L. Caracci's and Caravaggio's influence. Later in life he softened the harshness of his light and shade contrasts by more harmonious colouring in Guido Reni's style. He left a very large number of pictures. His masterpieces are considered to be the fresco of 'Aurora,' in the Villa Ludovisi; the 'Death of Dido,' in the Spada Palace; and 'Saint Petronilla,' in the Capitoline Gallery, all three at Rome.

Guericke, Heinrich Ernst Ferdinand (1803–78), a theologian belonging to the Old Lutheran school, was professor at Halle, and author of a well-known *Handbuch der Kirchengeschichte* (1853; 9th ed. 1866–67); of a *Christliche Symbolik* (1839; 3d ed. 1861); and of a *Lehrbuch der Christlichen Archäologie* (1847; 2d ed. 1889).

Guericke, Otto von, a celebrated physicist, was born at Magdeburg, in Prussian Saxony, 20th November 1602. His personal history contains nothing of interest. As a natural philosopher he is chiefly known by his experiments regarding the nature and effects of air, his discovery of the air-pump (1650), and of the Magdeburg Hemispheres (q.v.). He made also some notable observations in electricity. He was for a time engineer in the Swedish army, and afterwards Burgermeister of Magdeburg. He died at Hamburg, 11th May 1686.

Guerillas, the name given to armed bands who, on occasion of foreign invasion or civil war, carry on an irregular warfare on their own account. This class of fighters belong peculiarly to Spain, where from 1808 to 1814 they were systematically organised against the French, whose operations they very seriously embarrassed. The country itself also suffered from them. Many of them, particularly Mina's band, joined Wellington, and, after having undergone a course of discipline, rendered signal service as regular troops. On the conclusion of peace large numbers were organised into robber-bands. In most of the civil wars of Spain since 1820 guerilla warfare, especially in the Basque provinces, has played a prominent part. See Brigands.

Guérin, Georges Maurice de, a young poet of exceptional genius, was born at the château of Le Cayla in Languedoc, 4th August 1810, and was educated for the church at a Toulouse seminary and the Collége Stanislas, Paris, after which he entered the community gathered together by Lamennais at La Chesnaye in Brittany, but followed his master in his estrangement from Rome and renounced his novitiate in October 1833. He next went to Paris to try journalism, and became a teacher at the Collége Stanislas, but married a rich Creole lady in November 1838, and entered on a new life of rest and happiness, which was cut short by his untimely death of consumption, 19th July 1839. An article by George Sand in the *Revue des Deux Mondes* (May 15, 1840) first drew attention to his genius: his *Reliquiæ*, including the *Centaur* (a kind of prose poem), letters, and poems, were published in 1860, edited by G. S. Trébutien, with a critical notice by Sainte-Beuve. In the words of the latter, 'no French poet or painter has rendered so well the feeling for nature—the feeling not so much for details as for the *ensemble* and the divine universality, the feeling for the origin of things and the sovereign principle of life.'— Eugénie de Guérin, his sister (1805–48), had something of her brother's genius grafted upon a profound and mystical religion, and devoted herself with more than sisterly devotion to his memory. Her own *Journals* were published in 1861; her *Lettres*, in 1864. Both were translated into English.

See Sainte-Beuve, *Causeries du Lundi* (vol. xii.) and *Nouveaux Lundis* (vol. iii.); Marelle, *Eugénie et Maurice De Guérin* (Berlin, 1869); Harriet Parr, *M. and E. De Guérin, a Monograph* (1870); and Matthew Arnold's *Essays in Criticism* (1865).

Guérin, Pierre Narcisse, Baron, French painter, was born at Paris, 13th May 1774. A pupil of Regnault's, he first attracted notice by his 'Marcus Sextus' (1799), the first of a series of classic subjects, skilfully treated, but showing something of melodramatic effect. After a visit to Rome and Italy in 1802, he settled in Paris. From 1822 to 1829 he was director of the French Academy of Painting in Rome, and he died there on 6th July 1833. Amongst his pupils were Géricault, Delacroix, and Ary Scheffer.

Guernsey, the second in size of the Channel Islands (q.v.). It is about 30 miles in circumference, and 28 sq. m. in area. Pop (1861) 29,805; (1881) 32,638; (1891) 35,287—with Herm and Jethou. The lowest part is to the north (L'Ancresse), the highest to the south (Haut Nez) being 349 feet above sea-level. St Peter Port, the only town, has a good harbour, open at all tides; there is a large public school, founded 1563, and named after Queen Elizabeth; a fine church, dating from the 13th century, which has been well restored; a library with museum and lecture-rooms due to the beneficence of Messrs Guille and Allés; and another at Candie House, founded by the late O. de B. Priaulx. There is also a good public market, a ladies' college, poor-house, and lunatic asylum. Guernsey consists entirely of primitive rock covered with gravel and a surface of sandy loam. The climate is equable and favourable to the growth of fruit, flowers, and vegetables. Two-thirds of the island are under cultivation, and great quantities of fruit and vegetables are exported to England, as is also a hard gray granite much used in building. It is 127 miles from Land's End, 109 from Falmouth, 113 from Southampton, 69 from Start Point. Steamers to England daily, Sundays excepted. Taxation is light; the annual revenue of the bailiwick—which includes Alderney and Sark

is £30,000, derived from harbour dues, excise, market dues, and sundry other sources. The island is divided into ten parishes each administered by a *douzaine* of twelve ratepayers. There is a separate lieutenant governor for Guernsey appointed by the crown, and the constitution is similar to that of Jersey (q.v.), but more oligarchic. It is said that there are no moles or reptiles in the island.

Guerrazzi, FRANCESCO DOMENICO, Italian patriot and brilliant writer, was born at Leghorn, 12th August 1804, and, educated for the legal profession, won a great reputation among his countrymen by his political fictions, which exercised an immense influence on contemporary Italian events by their exalted strain of patriotic enthusiasm. Guerrazzi's own words are, 'he wrote a book when impotent to fight a battle.' On the eve of the definite breach between the people and the Grand-duke of Tuscany in 1849, Guerrazzi was induced to accept office in the ministry. On the flight of the Grand-duke he was proclaimed member of the provisional government, and subsequently dictator. During this crisis of the state he energetically refused his adhesion to 'the substitution of republicanism for monarchy;' and preserved the strict autonomy of Tuscany until the return of the grand-ducal rule. Then he was immediately seized and imprisoned on the grounds of having neglected due measures of repression when the revolution first gathered strength during his ministry. His defence, entitled *Apologia della sua Politica di F. D. Guerrazzi* (1857), is a masterpiece. After an imprisonment of three years, he was condemned for life to the galleys, but was subsequently permitted to select Corsica as the refuge of his perpetual banishment. Restored to liberty and action by later events, Guerrazzi sat in the parliament of Turin in 1862 and 1865. He died 23d September 1873. His chief works of fiction are *La Battaglia di Benevento*, remarkable for exquisite expression and beautiful poetic imagery (1827, fifty times reprinted); *L'Assedio di Firenze*, a magnificent historical novel, treating of the downfall of the republic of Florence (1836, more than thirty times reprinted); *Isabella Orsini* (1844); *Beatrice Cenci* (1854); *L'Asino* (1857). There are works on Guerrazzi by Cerona (1873), Fenini (1873), and Bosio (1877); and Carducci has edited his Letters (2 vols. Leghorn, 1880–82).

Guerre'ro, a southern state of Mexico, on the Pacific, with an area of 22,863 sq. m. It is a broken mountainous country, rich in minerals, fertile in the upland valleys, and enjoying a favourable climate except on the coast. Pop. (1895) 417,621. Capital, Chilpancingo (6000); chief port, Acapulco (q.v.).

Guesclin, BERTRAND DU, Constable of France, was born of an ancient family near Dinan in the district of Rennes, about either 1314 or 1320. From his boyhood upwards he excelled in all martial exercises. In the contests between Charles de Blois and Jean de Montfort for the dukedom of Brittany he took part with the former, especially distinguishing himself at Vannes (1342). After King John had been taken prisoner by the Black Prince at the battle of Poitiers in 1356, Du Guesclin contended successfully against the English, his valour and military skill being especially shown at Rennes (1356) and Dinan (1357). Then, entering the service of the Dauphin, afterwards Charles V., he took Melun (1359) and several other fortified towns, and freed the Seine from the English. On Charles's accession to the throne in 1364 Du Guesclin was created governor of Pont orson, and in May of the same year gained the battle of Cocherel against Charles the Bad of Navarre. But on the 29th September following he was defeated and taken prisoner by the English, under Sir John Chandos, at the battle of Auray, and only liberated on payment of a ransom of 100,000 livres. He next supported Henry, Count of Trastamare, against Pedro the Cruel, king of Castile, but was defeated and taken prisoner by the Black Prince near Najera (1367). Being again ransomed on payment of a large sum, Du Guesclin renewed the contest, and in 1369 defeated and captured Pedro at Montiel, and placed the crown of Castile on the head of Henry of Trastamare. Immediately afterwards he was recalled by Charles V. of France, at that time hard pressed by the English, and was raised to the dignity of Constable of France. In the year 1370 Du Guesclin opened his campaigns against the English, and in a few years the whole of their possessions were in the hands of the French, with the exception of a few fortified towns. While assisting at the siege of Châteauneuf de Randon, in Languedoc, Du Guesclin was taken ill, and died July 13, 1380. See Lives of him by Cuyard de Berville (1767; new ed. 1882), Jamison (1863), Luce (1883), and Postel (1893).

Guess, GEORGE. See CHEROKEES.

Guest, EDWIN, a learned antiquary, born in 1800, entered Caius College, Cambridge, in 1819, was eleventh wrangler in the Mathematical Tripos of 1824, and was thereafter elected to a fellowship. He was called to the bar, but did not practise, and early gave himself to antiquarian and literary studies. The only book he published was his well-known *History of English Rhythms* (1838; 2d ed. revised by Professor Skeat, 1882)—a work of great erudition, and written, moreover, before the era of good editions of old English poetry had begun. His frequent papers on the early history of Roman and Saxon England and the English were printed in the *Archæological Journal* and the *Transactions* of the Archæological Institute and other learned institutions, and earned the praises of scholars so critical as Mr Freeman. These were collected posthumously, filling the second volume of *Origines Celticæ (a Fragment), and other Contributions to the History of Britain* (2 vols. 1883). The first volume was devoted to the Celts and their ethnological and philological affinities; but, truth to tell, this work, laborious as it is, was conceived in a pre-scientific spirit, and its elaborate etymologies are valueless. In 1852 Guest succeeded Dr Chapman as Master of Caius College, Cambridge, and next year received the degree of LL.D. He became F.R.S. in 1841, and was Vice-chancellor of the university in 1854. He resigned the mastership but a few weeks before his death, which took place on November 23, 1880.

Gueux, or 'The Beggars,' the name assumed by the confederated nobles and other malcontents who opposed the introduction of the Inquisition into the Low Countries by Philip II. of Spain. Forming themselves into an association, November 1565, they presented, on 5th April following, a formal protest to the regent, Margaret of Parma. Their distinctive party name they adopted from an abusive epithet applied to them on that occasion by one of Margaret's courtiers. The 'beggars,' who represented the national feeling of the country, maintained a long and vigorous contest against the despotic proceedings of Philip and his advisers, but were ultimately compelled to succumb to superior force. A branch of them, 'the Beggars of the Sea,' under the leadership of the bold Count de la Marck, seriously harassed the Spanish fleet, captured transports with supplies for Alva's army, seized several fortresses, and succoured besieged places along the coast. Their capture of Briel in April 1572 was the beginning of the war which

terminated in the independence of the Netherlands in 1648. See HOLLAND.

Guevarism. See EUPHUISM.

Guevi. See ANTELOPE.

Guglielmi, PIETRO, a celebrated musician and composer, was born at Massa di Carrara in May 1727. His first opera, composed at the age of twenty-eight, was greeted with enthusiasm at Turin. He visited the chief cities of Italy, everywhere with success. After a residence of some months at Dresden and various other towns, Guglielmi passed over to London, where he remained five years. At the age of fifty he returned to Naples with the double prestige of great fame and wealth, and in 1793 Pope Pius VI. appointed him *Maestro di Cappella* at St Peter's. He died 19th November 1804. Among his most popular operas were *La Didone; Enea e Lavinia; I due Gemelli; La Serva Innamorata; La Pastorella Nobile; La Bella Pescatrice.*

Guiana, in its widest signification, is the region lying between the Orinoco and the Amazons in South America, with the Atlantic on the east and no definitive boundaries on the west. It consists of five divisions, known respectively as Venezuelan, British, Dutch, French, and Brazilian Guiana, the first named situated to the west of the next three, and the last named to the south of all four. But both Venezuelan and Brazilian Guiana being incorporated in those states, we have to describe here only British, Dutch, and French Guiana.

These three colonies abut upon the Atlantic, in the order named, between Venezuela on the north and Brazil on the south. The physical conformation is practically the same in all three. Next the Atlantic is a fringe of alluvial soil, lying in many parts below the sea-level, and generally inundated in the rainy seasons, with mud-flats skirting the coast and sandbanks jutting out into the ocean; these last are generally held together by the roots of mangrove-trees, though not unfrequently they are of a shifting character, forming temporary islands and moving about under the impulse of wind and tide and river current. This alluvial zone, varying in width from 10 to 40 miles, and consisting principally of blue argillaceous soil, of very great fertility, contains virtually the only cultivated territory in the three colonies. Beyond it the contour rises by a series of short terraces or land waves up to an undulating savannah region of moderate elevation (average 150 feet), which is formed geologically of the accumulated detritus brought down from the primitive mountain masses in the interior. The third and innermost division of colonial Guiana consists of the upland country, a plateau region ridged with mountain-chains (which rise in places to 3000 or 3500 feet), and everywhere covered with a dense primeval forest, exceptionally rich in magnificent timber-trees—rich not only in the quality of the timber, but also in the variety of the species. This division is as yet almost wholly unknown, save that the courses of most of the larger rivers have been explored to their sources.

Rivers.—The whole of Guiana is well provided with rivers. Most of them flow north or north-east to the Atlantic, and bring down with them vast quantities of sedimentary matter, which becomes deposited as the alluvial mud of the coast. These streams, although they are of admirable service for irrigation purposes, are of little use as waterways for navigation, owing to the mudbanks which choke their mouths, the sandbanks which obstruct their channels, and the numerous falls and cataracts by which their waters descend from the highlands and savannah plateaus to the low-lying coastal belt. Up to the line of the rapids and falls, however, they are navigable by small vessels for distances varying from 10 to 150 miles. Several of them are connected together in their lower courses by cross-channels and artificial canals. Indeed, communication in the colonies is principally effected by water, not by land.

Climate.—The climate, as beseems a region lying between 1° and 8° N. lat., is hot and moist, but on the whole tolerably uniform. Generally speaking, the thermometer ranges from a maximum of 95° to a minimum of 70° F.; the average, however, deviates but little from 80° to 84° F. The heat is tempered by sea-breezes during greater part of the year. The rainfall is heavy; the average for British and Dutch Guiana is 75 to 100 inches annually, and in French Guiana it is still heavier, sometimes reaching 140 inches in the year. The precipitation is, however, greatest in the interior; hence the great number of rivers fed from the wooded mountain-slopes inland. Two rainy and two dry seasons are distinguished: the former last as a rule from December to February and from April to August. Hurricanes are extremely rare.

Flora.—As would be expected from the nature of the country, vegetation is of extraordinary richness and luxuriance. Many of the numerous timber-trees are valuable for shipbuilding, house-building, roofing, cabinetmaking, &c. Several useful gums are yielded, and also balsams, wax, bark, fibre, oil, nuts, juices, medicinal preparations, &c., caoutchouc, balata gum, copaiba balsam, carapa-seed oil, sarsaparilla, cinchona, laurel oil, calabashes, silk cotton, tonqua beans, arnotto, Bromelia flax, angelica, cotton, tobacco, &c. The best-known food-plants comprise the cassava, sweet potato, arrow-root, capsicum or Spanish pepper, tomato, guava, cherry, avogato, bread-fruit, melon, granadilla, banana, pine-apple, earth-nut, yam, rice, and maize. Besides these there is a prodigious quantity of creepers, ferns, tree-ferns, and flowers; amongst these last must be specially named the orchids, which often form a continuous carpet along the tops of the forest trees, and the magnificent Victoria regia lily.

Fauna.—The most conspicuous branch of the fauna is the birds, the most characteristic forms being the stink-bird (a vulture), eagles, owls, nightjars, humming-birds, the bell-bird, several passerine species, orioles, a wren, toucans, jacamars, trogons, puff-birds, kingfishers, anis, parrots, the cock of the wood, curassows, tinamous, trumpeters, the jacana, the horned screamer, sand-pipers, the sun-bittern, herons, ducks, and divers. Mammals are not so plentiful as the extensive uninhabited forests might perhaps suggest. They are represented by jaguars, tiger cats, peccaries, tapirs, deer, sloths, armadillos, ant-eaters, agoutis, capybaras, opossums, raccoons, coatis, porcupines, squirrels, monkeys, martens, fish-otters, and manatees. Other forms of animal life are swarms of insects, including butterflies, crickets, mosquitoes, sandflies, and jiggers; turtles and tortoises, crocodiles, iguanas, frogs, snakes, including the anaconda and whip snakes; several Siluroid fishes, the electric eel, rays, sharks, and the sawfish.

Indians.—The native Indians, who still for the most part lead a 'wild' life in the forests, constitute several different tribes, and seem to belong to what were probably two distinct stocks, the indigenes and their original conquerors, the Caribs. In many parts of Guiana rude attempts at picture-writing exist on the rocks and faces of the hills. Two varieties have been discriminated—one deeply incised, the other merely scratched. Who the authors were is not known with certainty; they are generally believed to have been the ancestors of the existing Indians, who, however, have

preserved no traditions relating to the inscriptions.

History.—The first Europeans to explore the coast of Guiana seem to have been the Spaniards Alonzo de Ojeda in 1499 and Vicente Pinzon in 1500. Several attempts were made by adventurers of different European nations to found colonies in this region in the later part of the 16th and the early part of the 17th centuries. To this period belong Raleigh's and the other expeditions which visited this part of South America in search of the fabulous gold city El Dorado (q.v.) and the Lake of Parima. Apart from semi-buccaneering expeditions and landings, the first successful colonisation of Guiana seems to have been made by the Dutch, on the Essequibo, shortly before 1613. The English got firm footing at Surinam in 1650, and the French on the Kourou and Oyapock in 1664. Two years later the English seized both French and Dutch Guiana, but restored them in 1667, and at the same time handed over Surinam to the Netherlands in exchange for New Amsterdam—i.e. New York. The French, in 1674, renewed their attempts to settle at Cayenne, and with success; that part of Guiana has remained in their hands ever since. Except for two short periods (1781–83 and 1796–1802), the settlements on the Essequibo, Demerara, and Berbice and in Surinam were held by the Dutch down to 1803, when they were again taken possession of by the English, who at the peace of 1814 restored the last named, but retained the first three. Berbice was at first administered as a distinct colony, but in 1831 it was incorporated with the rest of British Guiana. During slave-holding times sugar-planting brought some degree of prosperity to these colonies; but their productiveness in this respect was very sensibly crippled by the abolition of slavery, which deprived them of their supplies of the requisite kind of labour for the plantations. Since that event coffee and cotton have almost entirely ceased to be grown; and the cultivation of beetroot for sugar caused a serious crisis in Guiana cane-planting. British and Dutch Guiana, however, still show signs of vitality: the cane-sugar industry, if not reviving, is at least not retrograde, whilst gold-mining is a decidedly progressive industry. Except for gold-mining, which however remains stationary, French Guiana is in a hopelessly deplorable condition.

British Guiana, or Demerara, with a coast-line of 320 miles, is separated from Dutch Guiana on the E. by the river Corentyn; on the S. and W., next Brazil and Venezuela respectively, the boundaries have never been definitively determined. The British make the limits of the colony extend southward to the sources of the Essequibo in the Acarai Mountains (about 1° N. lat. and 59° W. long.), and trend thence nearly due east to the head-waters of the Corentyn, whilst the west boundary (going north) coincides with the Takutu and Cotinga as far as Roraima; thence it proceeds north-east to the Imataca range and onwards north to the mouth of the Amacuro. The Venezuelans, however, claim all the region west of the Essequibo right up to the sources of this river. The area of British Guiana is approximately set down at 96,000 sq. m. The western part of the colony is diversified by chains of the Pacaraima or Parima mountain-system, which stretch generally from west to east, as the Imataca range in the north, the Merumé or Pacaraima Mountains, which rise to 3000 feet between 4° and 5° 30′ N. lat., and to some 8000 or 9000 feet in the table-topped Roraima (q.v.), and the Acarai Mountains, which form the southern boundary of the colony as well as the watershed between the Essequibo and the feeders of the Amazons. Between the two ranges last mentioned comes an eastward extension of the great Brazilian savannah region. The more important rivers are the Corentyn, Berbice, Demerara, Essequibo (with its tributaries, the Rapununi and the Mazuruni, and the Cuyuni, an affluent of this last), Waini, and Barima, all flowing north into the Atlantic; and the Takutu, which, supplemented by the Ireng and Cotinga, feeds the Rio Branco, a left-hand tributary of the Amazon. For the disputed Venezuela frontier, the subject of prolonged negotiations which led in 1895 to a threatening message from the President of the United States, see Venezuela.

The leading industry of the colony is the cultivation of the sugar-cane. Wood-cutting and gold-mining are the only other industries of any moment. The exports embrace sugar, average value £1,200,000 per annum; rum to the amount of nearly £100,000; molasses £20,000; timber, shingles, charcoal, cocoa-nuts, balata, and gums. The export of gold increased from £9000 in 1884 to £500,446 in 1894. The total value of the exports, which go principally to the United Kingdom and West Indies, fell from £3,208,631 in 1882 to £2,039,900 in 1895. More than half the exports go to the United Kingdom. The imports (mostly from the United Kingdom), which consist chiefly of flour, rice, dried fish, butter, pork, and beef, fell from £2,224,000 in 1883 to £1,668,750 in 1895.

In 1894 the population was 280,869, and embraced Europeans, Creoles, negroes, coolies from India, Chinese, natives of Madeira and the Azores, and aboriginal Indians; but of these last only some 10,000 are included in the census return. The negroes number 100,000, the East Indians 106,000, the Chinese 3800, the Europeans 2600. Most of the plantation work is done by immigrant coolies from British India and by Chinese.

The colony is divided into three counties, Berbice, Demerara, and Essequibo. The ports are Georgetown (q.v.), the capital, and New Amsterdam. The administration is in the hands of the governor, appointed by the crown, and two legislative councils—the Court of Policy (15 members) and the Combined Court (23 members)—the latter having the control of the finances. Slavery was abolished in the colony in 1834, though the importation of slaves from Africa had practically ceased twenty years before. Compensation was paid to the amount of £4,297,117 for 84,915 slaves (£50, 12s. per head). The colony possesses one line of railway, from Georgetown to Mahaica (21 miles long), telegraphic communication with Europe and the United States, and a good system of postage.

Dutch Guiana, or Surinam, with an area of 46,058 sq. m., and a coast-line of 240 miles, has for its boundary on the west the river Corentyn, on the south the Acarai Mountains and their eastern continuation, the Tumuc-Humac Mountains, and on the east the Maroni or Marowijn, which separates it from French Guiana. It is, however, a matter of dispute between the French and the Dutch which of the two upper branches of this last river—the right-hand arm, the Awa or Lawa, or the left-hand arm, the Tapanahoni—is the upper part of the main stream. The Dutch claim that it is the former, the French the latter. The other rivers of the colony are the Surinam, Saramacca, Coppename, and Nickerie, all flowing into the Atlantic. The greater part of the surface is covered with unexplored primeval forest, scarcely more than 210 sq. m. of the entire area being cultivated. The chief products are sugar, cocoa, gold, rum, molasses, bananas, rice, corn—of which sugar, cocoa, and gold are largely exported. The total annual value of exports is from £300,000 to £500,000; that of imports is from £400,000 to £600,000. Gold-mining has made rapid strides since 1875; the export

having increased in value from £2079 in 1876 to £90,461 in 1886, and £132,400 in 1893, though probably one-fourth more is smuggled out of the colony. In the year 1887 new discoveries of gold were made in the district between the rivers Tapanahoni and Awa, the region, some 8000 sq. m. in extent, which is in dispute between Holland and France. Trade is carried on principally with Holland, the United States, and Great Britain and her dependencies. There is a governor, a supreme council of five (all nominated), and a partly elected colonial assembly. The population, which is very heterogeneous, in 1894 numbered 62,649, of whom nearly one-half live at Paramaribo (q.v.) the capital. In 1884 the total was given at 52,978. Besides these there were about 4000 Bush Negroes —i.e. negroes who escaped during slavery times and subsequently asserted their independence— and 1200 Indians. As in British Guiana, labour is principally performed by coolies from British India and by Chinese. The colony is divided into eight administrative districts and the town of Paramaribo, and is under the charge of a governor, assisted by an executive council. The members of the provincial estates, the legislative body, are elected by the people. Slavery was abolished in 1863.

French Guiana, or Cayenne, is separated from Dutch Guiana on the west by the Maroni, from Brazil on the south by the Tumuc-Humac Mountains, and from the same country on the east by the Oyapock, although the French claim all the coastal districts as far south as the Amazons. The treaty boundary is the 'river of Vicente Pinzon,' the identity of which is the point in dispute; the French government, however, in 1856 expressed itself as willing to recognise the Araguary as the treaty stream. The north and north-east sides of the colony are washed by the Atlantic. Taking the Oyapock as the provisionally accepted boundary, the area of the colony is about 31,000 sq. m., whilst the length of coast-line is about 240 miles; the area, as officially given, is 46,850 sq. m. The coast is not so uniformly low and regular as in British and Dutch Guiana. Cayenne (q.v.), the capital of the colony, stands on a rocky promontory, and a little farther to the north-west lie the Safety Islands (Îles de Salut), behind which is the best roadstead in the colony. The undulating, heavily-timbered savannah region is crossed by one or two ranges of granite hills, nowhere exceeding 2600 feet in height. The culminating ridge, the Tumuc-Humac Mountains, only rises 1000 feet higher. The more important rivers, which all flow into the Atlantic, are the Maroni, Mana, Sinnamary, Kourou, Approuague, and Oyapock.

The commerce is almost nil, the only exports being cocoa and arnotto (roucou), each to the extent of about 750,000 lb. annually. A little coffee is grown. Gold is mined, however, and something like a value of £200,000 is annually exported; perhaps half as much again is smuggled out of the country. The total exports, exclusive of gold, have a value of some £20,000, and the imports of some £400,000. The colony costs the mother-country £250,000 a year. The population of the entire colony, exclusive of some mountain tribes, only amounted to 26,000—more than half in Cayenne—in 1895, and is slowly but surely diminishing; the marriages of people of European blood show great sterility, and infant mortality is large. The prevailing diseases of the swampy coast-lands are malarial fever, dysentery, anæmia, and yellow fever. From 1853 to 1864 an attempt was made to found penal colonies in French Guiana, all of which proved disastrous, partly owing to the unhealthiness of the climate, and partly to the harsh and ill-devised regulations in force for the management of the penitentiaries. The immigrant criminals now come (since 1864) exclusively from Africa (Arabs and negroes) and Asia (Annamites). Slavery was abolished in 1848.

Géog. de l'Est* (1886-87) and *Rev. de Géog.* (1888). See also *Annals of Guiana* (1888), by Rodway and Watt; and *Kaart van Guiana*, by W. L. Loth (Amsterdam, 1880).

Guiana Bark, French, the bark of *Portlandia hexandra*, also called *Couteria speciosa*, a tree of the natural order Cinchonaceæ, with opposite ovate leaves, and corymbs of very large purple flowers, a native of Guiana. The bark is esteemed a very powerful febrifuge, and the value of *Warburg's Fever Drops* is believed to depend mainly upon it.

Guicciardini, Francesco, an Italian statesman and historian, was born of noble parentage at Florence in 1483. The combined studies of law and literature engrossed his attention at first; and at the age of twenty-three he was elected professor of Law at Florence, where he also practised as an advocate. But his real field was diplomacy and statesmanship, as understood at that time in Italy —the diplomacy and statesmanship of Macchiavelli. His apprenticeship served in Spain (1512–14), he became papal ruler of Modena and Reggio (from 1515) under Leo X. and Clement VII., and afterwards of Parma (1521), the Romagna (1523), and Bologna (1531). Retiring from the service of the pope in 1534, he was mainly instrumental in securing the election of Cosmo de' Medici as duke of his native city, Florence. But, being disappointed in his ambitious design of acting as mayor of the palace to this young prince, Guicciardini withdrew to Arcetri, and busied himself, till his death in 1540, with the composition of a great work, *Storia d' Italia*, a dispassionate and coldly analytical history of Italy between 1494 and 1532. This work was edited by Rosini in 10 vols. (Pisa, 1819). In 1857–67 there appeared at Florence, in 10 vols., the *Opere Inedite* of Guicciardini, containing *Ricordi Politici*, a series of aphorisms on political philosophy; *Reggimento di Firenze*, a discourse on the forms of government suited for an Italian state; and *Storia Fiorentina*. See *Edinburgh Review* (1869); and Gioda, *Guicciardini e le sue opere inedite* (Milan, 1880). His *Maxims* were translated into English by N. H. Thomson in 1890.

Guicowar (*Gaikwar* or *Gáekwár*), the designation of a powerful Mahratta prince, ruler of the state of Baroda (q.v.) in Gujarat. Piláji, who became Guicowar in 1721, by predatory excursions gradually acquired authority over Gujarat; and his son Damáji ultimately threw off his allegiance to the Peishwa. Malhar Rao, installed in 1871, was in 1873 accused of attempting to poison the British Resident, tried, and deposed. See Baroda.

Guidebooks. When in 1829 Mr John Murray began that series of travels, personal observations, and private studies which issued in 1836 in his

Handbook for Holland, Belgium, and North Germany (the first work in English to which the name of 'Handbook' was applied), there was in existence no such thing as a guidebook to Germany, France, or Spain, other than such books as Howell's *Instructions for Forreine Travell* (1642) and its successors. The only works deserving the name of guidebook were J. G. Ebel's *Anleitung* for Switzerland (Zurich, 1793; 8th ed. 1843); William Boyce's *Belgian Traveller* (1815); and Mrs Mariane Starke's *Directions for Travellers in Italy* (1820). In the long series of his guidebooks Murray had the assistance of many notable authors—of Richard Ford for Spain, Sir Gardner Wilkinson for Egypt, Sir F. Palgrave for North Italy, Dr Porter for Palestine, &c. Murray's guidebook served as the foundation for the first of Baedeker's, the German guide to Holland and Belgium, and these in their turn inspired those of Baddeley and others. Most of Baedeker's numerous guidebooks are translated into English, and are as well known as Murray's even to English travellers. Other well-known series of guidebooks are those of Appleton and A. & C. Black. For France, the most accepted authorities are the guides of Joanne; for Italy the (German) guide of Gsell Fels is admirable; for Norway Tonsberg's (in English) deserves to be mentioned. Countless guides have been written for all places of special interest both in England and the Continent. An admirable series of short practical books intended to embrace all the English counties is that of the Tourist Guides published by Edward Stanford. The most illustrious writer who has written a guidebook is Wordsworth, whose *Guide to the English Lakes*, written for Wilkinson's *Select Views* in 1810, was printed separately in 1822.

Guides, in military affairs, are usually persons drawn from the country in which an army is operating, one or more being sent with every detachment of troops. A guide should be intelligent, quick of eye, experienced in the topography of the country, and, above all, faithful. As, however, guides must on many occasions be drawn from a hostile population, and have probably only a pecuniary interest in serving well, their conduct is always watched with the utmost jealousy, death being awarded as the punishment for the least departure from trustworthiness, since treason or incompetence might involve the most disastrous consequences to the whole expedition. In the French army a considerable corps of cavalry and infantry bear the name, but the name only, of 'guides.' They were first formed in 1744 as a small company of messengers on active service. The number was gradually increased until the time of Napoleon I., who formed them into a guard 10,000 strong. In the British Indian army the corps of guides of the Punjab Frontier Force (six troops of cavalry and eight companies of infantry) have acquired the name in a similar manner.

Guidi, Carlo Alessandro, an Italian lyric poet, was born at Pavia in 1650, and died in 1712. He was one of the founders of the academy called L'Arcadia.—For another Guidi, see Masaccio.

Guido. Guido Reni, a celebrated painter of the school of Bologna, was born near that city, at Calvenzano, on 4th November 1575. He studied under Calvaert, and at the age of about twenty entered the school of the Caracci, of which he and Domenichino were the most famous pupils. He is also stated to have learned the processes of fresco from Ferrantini. His earliest works, of which the 'Coronation of the Virgin,' in the National Gallery, London, is an example, are marred by rather harsh and violent colouring; but coming under the influence of Caravaggio, he adopted many of the qualities of his art, and his following works are characterised by forcible if exaggerated chiaroscuro. About 1596 he settled in Rome, where he worked for some twenty years, adopting a graceful style, of which the famous 'Aurora and the Hours,' painted on the ceiling of the pavilion of the Rospigliosi Palace, is a typical example. This is usually regarded as the masterpiece of the artist, but some competent critics rank even higher the unfinished 'Nativity,' in the choir of San Martino at Naples. The portrait titled 'Beatrice Cenci' (q.v.) in the Barberini Palace, Rome, is ascribed to Guido on very doubtful authority. He now entered upon the third period of his art, when he painted thinly, with great ease of execution and a cold silvery delicacy of colouring; but gradually his productions lost the vigour of his earlier time, when he had been more directly inspired by nature instead of by the study of Raphael and of such examples of the antique as the Niobe group. The decline of his art is also attributable to his extravagant habits and his passion for gambling, which obliged him to paint under pressure for the dealers, and to produce much hasty and ill-considered work. On account of a quarrel with the Cardinal Spinola regarding an altarpiece commissioned for St Peter's he left Rome and settled at Bologna, where he died 18th August 1642. He was a most prolific painter, and his works are to be found in all the chief European galleries. At the beginning of the 19th century they were very highly esteemed, but now—in common with the works of other post-Raphaelite Italian masters—they are less highly valued than formerly. In addition to his paintings Guido produced some vigorous and freely-touched etchings, including a portrait of Paul V. and several religious subjects after his own paintings and those of the Caracci. He had many pupils both at Rome and Bologna. Of these the most celebrated was Simone Cantarini, known as Il Pesarese, who painted an excellent portrait of his master, now in the Bologna Gallery.

Guido Aretinus, or Guy of Arezzo, is believed to have been born near Paris in 990, and to have come to Arezzo as a Benedictine monk. He died a prior at Avellana in 1050. He greatly influenced musical studies, and almost every discovery made in music for 150 years has been attributed to him, including that of descant, counterpoint, and (absurdly enough) the spinet. It seems, however, that it was he who first adopted as names for the notes of the scale the initial syllables, set to regularly ascending tones, of the hemistichs of a hymn in honour of St John the Baptist (*ut, re, mi*, &c.). Mr Rockstro holds it certain that he invented the principle on which the construction of the stave is based, and probable that he invented the hexachord, solmisation, and the 'Harmonic or Guidonian Hand,' a mnemonic method of indicating the order of the musical sounds on the finger-joints of the left hand. The fame of Guido's musical invention drew upon him the attention of the popes Benedict VIII. and John XIX., who invited him to Rome. Guido left writings explanatory of his musical doctrines, especially the *Micrologus* and the *Antiphonarium*. See monographs by Angeloni (1811), Kiesewetter (1844), and Falchi (1882); Rockstro in the appendix to Grove's *Dictionary* (1889); and the articles Music, Solfeggio.

Guienne, one of the old French provinces, comprehending the present departments of Gironde, Lot, Dordogne, Aveyron, with portions of Tarn-et-Garonne and Lot-et-Garonne. It formed with Gascony (q.v.) what was originally the country of Aquitania (q.v.), of which name Guienne is a corruption.

Guignes, Joseph de, born at Pontoise, 19th October 1721, acquired a great reputation as an orientalist, and, chiefly on account of his thorough knowledge of Chinese, was appointed interpreter of oriental languages in the Bibliothèque du Roi. He died in Paris, 19th March 1800. His great work, *L'Histoire Générale des Huns, Turcs, Mogols, et autres Tartares occidentaux* (1756–58), is a rare example of industry and research.—His son, Chrétien-Louis-Joseph (1759–1845), was also a very distinguished oriental scholar, and published a Chinese Dictionary (1813).

Guilandina, a genus of shrubs of the natural order Leguminosæ, sub-order Cæsalpineæ. *G. bonduc* and *G. bonducella* are the best-known species. Both are natives of the warm parts of the East Indies, Arabia, Africa, and South America. Egyptian mothers string the seeds of both species and hang them round the necks of their children, to guard them from evil influences and sorcery. The latter species is also called *Nicker Tree* and *Small Bonduc*. Being about the size and shape of marbles, the seeds are often used as such by boys. The shell is remarkable for its flinty hardness. The kernel is very bitter. Ground to powder and mixed with black pepper, it is administered in India in ague; mixed also with castor-oil it is applied externally in hydrocele. The roots in Amboyna are considered to be a good tonic. The seeds are often thrown ashore on the coasts of Scotland and Ireland, and are sometimes called *Molucca Beans*.

Guildford, the county town of Surrey, lies in a break of the chalk ridge of the North Downs, on the navigable Wey, 30 miles SW. of London. In Cobbett's phrase a 'happy-looking' place, it wears an air of order and cleanliness, and mainly consists of one street, running up the steep east side of the river, which here is crossed by an old five-arch bridge. Its houses are still rich in quaint gables, projecting fronts, and long latticed windows. The square Norman keep of its royal castle (*circa* 1150) is 70 feet high with walls 10 feet thick; on St Catharine's Hill is a ruined chapel (1313); Trinity Hospital, founded in 1619 by Archbishop Abbot (q.v.) for twelve brethren and eight sisters, is a picturesque red-brick pile; and other buildings are the churches of St Nicholas, St Mary, and the Holy Trinity, the guildhall (1687), county hall (1862), county hospital (1868), and grammar-school (1509–50). A railway junction of some importance, Guildford now is chiefly famous for its grain market, the 'Surrey wheats' being celebrated. From Edward I.'s reign till 1867 it returned two members to parliament, then till 1885 one. Since 1874 it has been the seat of a bishopric suffragan to Winchester. Pop. (1851) 6740; (1891) 14,319. Bequeathed in 901 by Alfred the Great to his nephew Ethelwald, Guildford in 1036 was the scene of the decimation by King Harold's men of the Norman followers of Alfred the Atheling—a crime that led up to the Norman conquest of England. The Dauphin Louis took the castle in 1216; and in 1685 Monmouth was temporarily confined in Trinity Hospital.

Guildhall, a building in London, the place of assembly of several courts, and the scene of the civic banquets of the city corporation, was originally built in 1411, but almost wholly destroyed by the great fire of 1666. It was rebuilt in 1789 in its modern form. See London.

Guilds were associations which grew up and flourished chiefly among the commercial and industrial classes during the middle ages. The word is derived from A.S. *gild* (Dutch *gild*, Ger. *gilde*) 'a payment;' the idea of payment may therefore be assumed to be the prominent original feature of the association. The letter *u* in the English spelling of the word, it may be added, is superfluous, *gild* being the correct form. The full meaning of the word was unfolded only in the course of the history of the institution.

It is one of the many debateable points connected with the guilds, whether and how far the medieval institution was preceded and influenced by similar societies in Greek and Roman times. In the *eranoi* and *thiasoi* of the Greeks, and still more in the *collegia opificum* of the Romans, many writers find a resemblance to the guilds. The whole matter is obscure, the historical evidence being scanty and doubtful. As the ancient economy rested on slavery, and guilds were the voluntary organisation of the industrial classes, such associations could not have been very widely diffused in the ancient world, if they existed at all. The probability is that the trade corporations of the later Roman period, though very different from the guilds, may have affected the early development of the latter. But the real origin of the guilds must be sought in the needs and circumstances of the time when they flourished.

The guilds known to history were an organisation of the commercial and industrial classes, determined by the economic, social, and political conditions prevalent during the middle ages. The most important of these conditions were the growth of freedom in the towns as opposed to the slavery of older times and the still existing serfdom of the country, the prevalence of a small industry operating for the most part in strictly defined local limits, and the absence of strong central governments. They were free local associations of the industrial classes for the promotion of their common interests at a time when central governments did not exist or were too weak to perform all the functions of government as now recognised.

As the cities, and the free life associated with them, arose but slowly in the Teutonic settlements after the wreck of the Roman empire, the guilds had at first a very gradual growth. The first mention of an institution so called occurs in England in the laws of Ina (7th century) and Alfred. We hear of it first on the Continent in the time of Charlemagne in 779. By the middle of the 9th century guilds were widely diffused throughout the Frankish empire. In the 11th century they began extensively to flourish in the countries settled by the Teutonic peoples; and they were powerful also in France and Italy, where the Teutonic influence had been only partially felt. In the 14th and 15th centuries the institution reached its culminating point.

Guilds were an historical institution varying with the times and with the needs and aims of their members; and it would therefore be misleading to attach too definite a meaning to the word. In some of them doubtless the distinctive features were periodic festivals defrayed by the contributions of the members. These were the social guilds. As during the middle ages the distinction between religious and secular was not so strongly marked as now, all the guilds had more or less of a religious cast. Many of them, however, had a distinctly and exclusively religious purpose, and are therefore specially called religious guilds. But the earliest great example of the historic guild was the *gilda mercatoria* or *gild merchant*. In the evolution of town life during the middle ages the commercial class was the first to assert itself. It does not fall within the scope of this article to explain the conditions under which the medieval towns arose; and we need hardly state that as the towns grew, the necessity for intercourse among themselves and with the surrounding country regions was soon felt. Within

the towns the advance of civilisation brought with it a multitude of crafts, the workmen in which organised themselves into the *craft guilds*. In many cases the guild organisation was identical with or grew into the government of the towns. But as the merchant guilds were first in the field, and moreover as the great merchants were frequently also the local landholders, the merchant guilds claimed and for a long time maintained a privileged position. Hence fierce and bitter struggles between the merchant and craft guilds, which after continuing for many generations ended on the whole in favour of the latter towards the end of the 14th century.

From what has been said it will be evident that the guilds had a far wider scope than the trades-unions of the present time. The distinction between labour and capital did not then exist; the guilds were an organisation of the whole industrial class, and they were associated with the business of local and civic self-government in the widest sense of the word. They were most powerful on the Continent, especially in the towns of Flanders and south Germany, where the civic life was strongest and the central government particularly weak; there the guild struggles, especially the struggle of the craft against the merchant guilds, were fought out most vigorously. In England, where after the Norman Conquest there had been a comparatively strong central power, the guilds found less scope for independent activity in that way.

The inner organisation of the guilds rested on the arrangement of the workers into master, journeyman, and apprentice. The right to the independent exercise of a trade depended on being member of a guild, and guild membership carried with it the privileges of citizenship. On the one hand, the guild had its own particular branch of industry reserved to it and a local market for its produce secured; on the other hand, the guild had to see that its members possessed the due qualifications, moral and technical, and that the work they turned out was of fair and reasonable quality. In other words the interests of producers and consumers were supposed to be reconciled on equitable terms. Those objects could be attained, and the guild organisation generally could be maintained only by a system of regulations, which were often very minute, and yet were not sufficient to prevent continual disputes between the various crafts. On the whole the guild organisation was best adapted to a stable condition of industry and of society.

The causes of the decline and fall of guilds have not yet been thoroughly investigated, but the main reason may be found in the fact that they became stagnant and did not adapt themselves to the conditions of modern progress. As they had grown up and flourished under medieval conditions, so they began to decay under the new influences which overthrew the medieval system. Under the centralised governments which rose on the ruins of feudalism, and during the great wars waged by them in the 16th and 17th centuries, the free civic life of Flanders and Germany was crushed out. In England the central power represented by Henry VIII. gave a severe blow to the guilds by confiscating their property on the plea that it was used for purposes of superstition; only the London corporations redeemed their funds by paying a fine of £18,700. The mercantile system was best adapted to such governments, and the guild organisation had to conform to the new system. Strong governments like France and Prussia regulated the guild organisation in the interest of the central power as then understood, the result being to deprive the members of free initiative and to make their constitution more rigid than ever. Above all, it was the great industry of more recent times which finally broke up and superseded the guild industry. This may be best illustrated by the early history of the steam-engine, which was at once the originating cause and the embodiment of the industrial revolution that made guilds a thing of the past. Because of the opposition of the trade-guilds of Glasgow, James Watt could pursue his experiments only within the limits of the university there. The skill, energy, and enterprise which produced the first effective steam-engine under Watt's initiative, were found at Birmingham, a town where trade corporations did not exist. These facts are typical of the whole movement. Guild restrictions, whether imposed by themselves or by strong central authority, were not consistent with the new industry, for which freedom was a prime necessity. This was at length recognised in the legislation of the most advanced countries of Europe. After a partially successful attempt by Turgot in 1776, trade corporations were entirely abolished in France at the revolution of 1789. All special industrial privileges enjoyed by guilds or corporations in England were removed by the municipal Reform Act of 1835. The North German Industrial Code of 1869 had the same effect in Germany. Thus the guild organisation, which during the middle ages realised the ideals of freedom, progress, and equity in such measure as was attainable by the men of that time, had become opposed to the wider claims of freedom, progress, and equity as now understood, and had to be swept away.

The name of guild has recently been revived in connection with associations for various social purposes, self-improvement, &c. These we need not say are entirely different from the old guilds, to which this name were better restricted. The co-operative society is the only institution existing in the western world that really corresponds to the historic guild. The London livery companies still continue, but they have lost the substantial characteristics of the organisations of which they are a survival and relic. Recent investigation, however, has shown that guilds have long flourished very extensively in China. The castes of India in many respects perform the same functions, industrial and social, as the medieval guild.

See the articles CO-OPERATION, TRADES-UNIONS, CITY, CORPORATION, HANSEATIC LEAGUE, &c. The whole subject of guilds has not yet been sufficiently investigated, and in some important cases the materials for such investigation no longer exist. Most of the documents relating to the guilds of Paris, for example, were destroyed during the revolutionary period of 1789. See L. Brentano, *On the History and Development of Gilds*, first published as preface to *English Gilds* by Lucy Toulmin Smith (1870), and appearing later as introduction to the same writer's *Arbeitergilden der Gegenwart* (1871); Ochenowski, *England's Wirthschaftliche Entwickelung im Ausgang des Mittelalters* (1879); Dr C. Gross, *The Gild Merchant: a Contribution to English Municipal History* (2 vols 1890); article 'Gewerbe,' by G. Schonberg, in Schonberg's *Handbook of Political Economy* (2d ed. 1886); E. Bain, *Merchant and Craft Guilds of Aberdeen* (1887); and Walford, *Gilds: their Origin and Constitution* (2d ed. 1889). For the earlier period of English guilds, W. J. Ashley's *Introduction to English Economic History and Theory* (1888) may be particularly recommended.

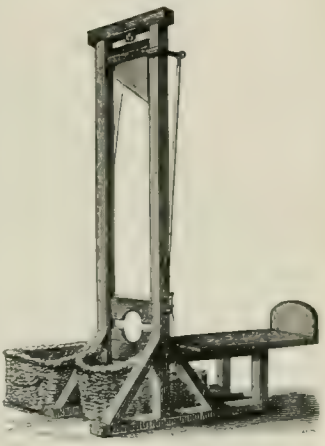
Guillemin, AMADÉE VICTOR, a popular writer on science, was born in Saône-et-Loire, 5th July 1826, and became a professor of Mathematics at Paris. Of his numerous illustrated works many have been translated into English, including *The Heavens* (1866), *The Sun* (1869), *The World of Comets* (1876), and *The Forces of Nature* (1872) and *Application of Physical Forces* (1877), the last two by Mrs Norman Lockyer. Both in France and England Guillemin's works have gone through many editions. He died 2d January 1893.

Guillemot (*Uria*), a genus of diving birds of the Auk family (Alcidæ), represented by eight species in the arctic and north temperate zones. The bill is moderately long, straight, and feathered to the nostrils; the feet are three-toed, the hind-toe being absent, and they are completely webbed. The wings and tail are short, and the legs are placed very far back, so that the bird stands erect. Its walk is awkward, and its flight heavy though well sustained; but it dives with great agility, using its half-opened wings to aid its progress. The guillemots breed in large colonies on rocky cliffs, building no nests, but laying their eggs on the bare rock, and the male shares with the female the labour of hatching and rearing the young. Their food consists of crustaceans and small fishes. The Common or, as it is often called, Foolish Guillemot (*U. troile*), is very abundant on the British coasts. In summer the head, neck, and upper parts of the body are of a dark brown, the under parts white, the bill, legs, and feet black; in winter the neck and some parts of the head are white or mottled brown and white. The male measures about 18 inches in length; the female is coloured like the male, but is slightly smaller. She lays only one egg, 3 inches in length, which she hatches by holding it between her legs as she sits erect facing the cliff. The eggs are pear-shaped, and vary in colour from pale green to a deep reddish-brown. It seems, however, as if one bird laid the same colour of egg in successive seasons. The Ringed Guillemot is sometimes considered as a distinct species (*U. ringvia*), but as it differs from the common guillemot only in having round the eyes a ring of white continued backwards as a fine line, and as it is never found except where the latter also occurs, most ornithologists now agree in regarding it as a variety. The Black Guillemot (*U. grylle*)—sometimes placed in a separate genus (Cepphus)—is found in Caithness and on the west coast of Scotland, and is fairly abundant in the Hebrides, Orkney, and Shetland. It is smaller than the preceding species, its length being only 14 inches, and it differs from it in laying two eggs. Its summer plumage is sooty-black, with the exception of white patches on the wing-coverts; and in winter the head and back have white markings, and the under parts are nearly white. In America *U. grylle* breeds as far south as the Bay of Fundy; *U. troile* is occasionally found on the coasts of New York. Where guillemots congregate in vast numbers, as at Flamborough Head, scaling the cliffs in search of their eggs is a regular profession, and one which requires much skill and courage. The eggs are occasionally used as food, as is also, indeed, the coarse flesh of the bird itself; but they are chiefly valued for their albumen, of which it is said large quantities are used in clarifying wine and in the preparation of patent leather. See Howard Saunders, *Manual of British Birds*.

Common Guillemot (*Uria troile*).

Guillim, John, heraldic writer, born in Herefordshire, about 1565, was most of his life an official of the College of Arms in London. In 1610 he published *The Display of Heraldry*, the materials for which, however, were supplied by John Barkham (*c.* 1572–1642), chaplain to the Archbishop of Canterbury. Guillim died 7th May 1621.

Guillotine, the instrument of decapitation introduced during the French Revolution by the Convention, and named after its supposed inventor, Joseph Ignace Guillotin, a physician (born 1738—died in his bed, not, as often said, by his own instrument, 1814), who, however, was only the person who first proposed its adoption. It was erected and first employed to execute a highwayman on the Place de Grève, Paris, 25th April 1792. It is composed of two upright posts, grooved on the inside, and connected at the top by a cross-beam. In these grooves a sharp iron blade, having its edge cut obliquely, descends by its own weight on the neck of the victim, who is bound to a board laid below. The invention of machines of this kind is ascribed to the Persians. In Italy, from the 13th century, it was the privilege of the nobles to be put to death by a machine of this kind, which was called *mannaia*. An instrument resembling the guillotine was likewise employed during the middle ages in Germany, where it has been reintroduced since 1853, and at a later date in France and Holland. During the 16th and 17th centuries a machine called the *Maiden*, which differed but slightly from the guillotine, was employed in Scotland for the purpose of decapitation; among its victims were one of Rizzio's murderers (1566), the Regent Morton (1581), and the Marquis (1661) and the Earl of Argyll (1685). Morton is commonly, but falsely, said to have introduced it, taking the idea from the similar engine at Halifax (q.v.), which was in use till 1650. See J. W. Croker, *History of the Guillotine* (1853); L'Abbé Bloeme, *Notice sur la Guillotine* (1865); Chereau, *Guillotin et la Guillotine* (1871); and Dubois, *Récherches historiques et physiologiques sur la Guillotine* (1881).—The name of guillotine is also given to a powerful machine used by bookbinders for cutting paper and cropping the edges of books, the blade having an oblique motion.



Guillotine.

Guilty. See Criminal Law.

Guimarães, an ancient and picturesque walled town of Portugal, on the Ave, 12 miles SE. of Braga. Here is the 14th-century Oliveira Church, and there are two noted hot sulphur-springs in the vicinity. Pop. about 8205.

Guinea, the name of a large section of the west coast of Africa, which first came into general use in the 15th century. Although the name is used with a different extension by different writers, it is pretty generally agreed that the stretch of coast-lands so designated extends from the mouth of the Senegal, in about 14° N. lat., to Cape Negro, in 16° S. lat. By conventional usage it is further divided into two parts, Upper and Lower Guinea, the dividing line being taken variously as the equator, the Gaboon, the Ogoway. The states and political territories comprised within this long

stretch of coast-line, commencing from the north, are as follows: the French colony of Senegal, the English settlements on the Gambia, the Portuguese territory of Bissáo or Bissajos, the coastal fringe before Futa-Jallon, Sierra Leone (British), the free negro republic of Liberia, the Ivory and Gold Coasts (shared between France and Britain), the Slave Coast (belonging to Germany, Britain, and France), the Niger delta (falling within the British sphere of commercial interest), and the Cameroons (German) in Upper Guinea; and in Lower Guinea, the Spanish settlements on Corisco Bay, the French colony of the Gaboon, the Congo Free State, and the Portuguese territories of Ambriz, Angola, and Benguela. The coast line is throughout tolerably uniform, and everywhere flat, with numerous shallow lagoons separated from the ocean by narrow spits of sand, lying parallel to the coast. Proceeding inland, the country rises to the central plateau of the continent by a series of broad terrace like steps, down which the longer rivers are generally precipitated in cataracts and rapids. The Genoese claim to have reached the coasts of Guinea in 1291. They were regularly visited by merchants from Rouen and Dieppe from 1364, but were not colonised until the Portuguese, under Henry the Navigator, sent out colonies hither (1481). The vast indentation of the Atlantic lying between Upper and Lower Guinea is called the Gulf of Guinea. Of late it is usual to restrict the name of Guinea to Upper Guinea, in which there are three ethnological groups: (1) Tshi-speaking tribes, the most barbarous, including the Ashantees; (2) Ehwe-speaking, including the Dahomeyans; (3) Yoruba-speaking, including the Egbas and other relatively civilised peoples. French influence has been greatly developed in Guinea of late, both on the coast and in the Hinterland. French Guinea, without Futa Jallon, the Ivory Coast, or Dahomey, includes Grand Bassam, Assinie, Grand Lahou, and Jackeville on the Gold Coast; and Porto Novo, Grand Popo, Kotonou, and Agoué on the Bight of Benin. See separate articles on GOLD COAST, &c.

Guinea, a gold coin current in Great Britain from 1664 down to 1817, when it was superseded by the Sovereign (q.v.), was at first coined out of gold from the Guinea coast. It was designed to be of the value of twenty shillings, and as legal tender it had no higher value till 1718. But its actual value

Guinea of Charles II.

varied. Thus in 1695 it was as high as thirty shillings, in 1697 twenty-two shillings, thereafter till 1717 twenty-one and sixpence, but was finally fixed at twenty-one shillings. It is still customary in Great Britain to estimate professional fees, honoraria of all kinds, complimentary subscriptions, prices of pictures, race-horses, &c. in guineas. In 'spade guineas' the reverse bears a spade-shaped shield with the royal arms.

Guinea Corn, a name sometimes given to Durra (q.v.); sometimes to a Millet (q.v.).

Guinea Fowl (*Numida*), a genus of African birds in the Pheasant family (Phasianidæ). The plumage is dark gray, with round spots of white, generally larger on the back and under surface. Some species are adorned on the head with a helmet or horny casque, while others have fleshy wattles on the cheeks and a tuft or top-knot on the crown. The genus is represented by nine species, in the Ethiopian region—east to Madagascar, south to Natal. The best known is the Common Guinea Fowl or Pintado (*N. meleagris*), also popularly

Common Guinea Fowl (*Numida meleagris*).

known as 'Come-back,' from its cry, with naked head, hard callous casque, and slate-coloured plumage, everywhere speckled with round white spots of various sizes. It is common in Guinea and southwards to the Cape of Good Hope. It is found also in more northern parts of Africa, and was known to the ancient Romans, by whom it was called *Meleagris* and *Gallina Numidica*, and highly prized. In their wild state the birds occur in flocks, sometimes of fifty to sixty, and are extremely shy and difficult to approach. They utter a frequent, harsh, and querulous cry. They are not so polygamous as many of the gallinaceous birds, and even in domestication show a tendency to pair. The guinea fowl is now common in the poultry-yards of most parts of Europe, although it is more adapted to warm than to cold climates, and in Jamaica has been completely naturalised, so as to be destructive to crops and to be shot like other game. In Britain the young are rather troublesome to rear, but both birds and eggs command high prices in the market. The eggs are small, and have a thick, strong shell, but are particularly esteemed. The flesh is somewhat like a pheasant's, but rather dry. Guinea fowls, however, are troublesome in a poultry-yard, from the disposition of the males to attack and tyrannise over other poultry.

Guinea Grass (*Panicum maximum*), a grass of the same genus with Millet (q.v.), a native of Guinea and Senegal, but introduced at an early period to the West Indies, where it is extensively cultivated, and by the abundance and excellence of its forage forms most important pasture. Other species of the same genus are among the most useful pasture and forage grasses of tropical countries.

Guinea Pepper, a name which has been variously applied to the seeds or dried fruit of several very different plants, agreeing in their peppery character, and in being the produce of the west of Africa. The name Malaguetta (Malagheta, Meleguetta, &c.) Pepper is generally to be regarded as equivalent with Guinea Pepper, and is at present a frequent designation of Grains of Paradise (q.v.); but the capsules or dry berries of *Capsicum frutescens* (see CAPSICUM) are commonly but erroneously

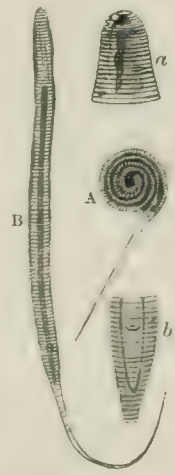
sold by druggists under the name Guinea Pepper; whilst the names Guinea Pepper, Malaguetta Pepper, and Ethiopian Pepper have been applied to the dried fruit of *Cubeba Clusii* (see CUBEBS), and to the seeds of *Habzelia* (or *Xylopia*) *Æthiopica*, a shrub of the natural order Anonaceæ. Up to the close of the 18th century Guinea Pepper continued in request, when the peppers of the East drove it from the market.

Guinea-pig, or CAVY (*Caria*), a genus of small South American rodents, widely represented in Britain by the familiar domesticated species. The genus, comprising nine species, is typical of the family Caviidæ (included in the porcupine-like section of Rodents), and is nearly related to the largest member of the order—the Capybara or Hydrochœrus. The guinea-pigs have short limbs, the fore-feet bearing four toes, the hind-feet only three; the fore-feet are not webbed; the upper lip is not cleft, the ears are short and rounded, and the tails are wanting. The Common Guinea-pig or Cavy (*C. cobaya*)—whose name Guinea is believed to be a corruption of Guiana—was introduced into Europe from South America in the 16th century. Its supposed wild original, the Restless Cavy (*C. aperea*), abounds on the banks of the La Plata,

Guinea-pig.

and is found in Bolivia and Brazil. Its colour is dark brown on the back and yellowish-gray underneath. It lives in small troops near the borders of forests, whence it emerges at dusk and on gloomy days in search of food. It is timid and stupid, and falls an easy prey to carnivores and serpents. The common guinea-pig resembles it closely in nearly all points except colour, which is very variable, as in other domesticated animals. The guinea-pig multiplies with great rapidity, and may begin to bear young when two months old, producing one to four at a birth, five or six times a year. The other species occur from the Strait of Magellan to Brazil, and one is found in Peru. Although now exclusively South American, fossil forms are said to have been found in the Miocene deposits of Switzerland and France. Some species of Cavia are shot for food, but no such use is made of the domesticated form.

Guinea-worm, known also as *Filaria Medinensis*, or *F. Dracunculus*, is a parasitic animal that seems to have been known from the earliest times. Plutarch quotes a passage from a still earlier author which seems clearly to refer to this worm. But our knowledge of its natural history is still very deficient, and we are at present only acquainted with the female. The body of this animal is slender, cylindrical, and somewhat compressed, and is of the thickness of pack-thread, except at the posterior extremity, where it is somewhat attenuated. It is opaque, of a milk-white colour; on each side there is a longitudinal line; and when examined by the microscope it is seen to be marked with numerous transverse striæ. The anterior extremity is obtuse and the mouth circular and beset with four acute spines. The length of the worm varies from less than half a foot to three yards. On examining an adult specimen, extracted by Malgaigne in Paris in 1854, Robin found no trace of intestine, or of any organ except a very thin sheath (a uterus or oviduct), which was filled with young animals rolled up in coils, with the tail occasionally projecting outwards (see A in the figure). In these young animals we can trace the course of the intestinal canal, which apparently becomes subsequently obliterated by the excessive development of the generative organs and the eggs.



Young Filaria Medinensis (magnified):

A, individual coiled up, as seen in the body of its parent; B, the same uncoiled in a drop of water: *a*, the head; *b*, the commencement of the tail and the anus.

This worm is indigenous only in certain hot countries, and its geographical distribution is regulated by laws into which we have no insight, save that heat and moisture are necessary for its production. Among places as especially notorious for its occurrence are Senegal, Gaboon, the banks of the Ganges, Bombay, the peninsula of India, Persia, Arabia Petræa, the south coast of the Red Sea, the region round the Caspian Sea, Upper Egypt, Abyssinia, certain districts of Nubia, the swampy regions of the White Nile, and Guinea. It has been introduced into certain parts of America by negro slaves. The disorder occasioned by these worms frequently becomes an epidemic in years of heavy rain, and especially in marshy districts. It appears also to be connected with the season, being especially prevalent in the East Indies during the rainy season, and in Upper Egypt shortly after the regular inundation of the Nile.

The mode of production of this parasite in the human body is not known with certainty. The probability is that the young animals while still very minute penetrate the skin, although by what mechanism they can effect their lodgment we do not know. Having gained an entrance into the body, the guinea-worm takes a considerable time to develop. This period varies from two months to a year or even two years. The presence of the worm often produces no annoyance for a considerable time after it has been detected; at other times it gives rise to emaciation, and possibly even death from exhaustion. As a general rule the vesicles caused by the inflammation excited by the presence of the worm open spontaneously in a few days, and two or three inches of the anterior end of the animal come forth. This end is gently pulled, and coiled round a little roll of linen or a small stick, and this is fastened over the wound with sticking-plaster and a compress. The extraction is repeated twice a day by rotating the substance round which the worm is twisted, and the operation is often not completed in less than two, three, or more months. From the most ancient times the tearing of the worm has been regarded as a very dangerous accident. It undoubtedly gives rise to violent swelling, fever, sleeplessness; and shortening and deformities of the legs, lingering fistula, mortification, and death (sometimes even sudden death) must be reckoned amongst the notable consequences of breaking the worm. See Quain's *Dictionary of Medicine*;

Linn. Trans. (1863); also the writings of Owen, Cobbold, and Bastian.

Guinegate, a village of Hainault, Belgium, where the French were twice defeated. (1) On 17th August 1479 they were beaten by Maximilian I. of Austria; (2) on 16th August 1513 by Henry VIII. and the Emperor Maximilian. This battle was called the Battle of the Spurs—the French knights having made more use of their spurs than of their swords.

Guines, formerly GUISNES, a small town (pop. 3800) 8 miles S. of Calais, was the scene of 'the Field of the Cloth of Gold' (see HENRY VIII.).

Guinevere. See ARTHUR.

Guingamp, a French town in Côtes-du-Nord, on the Trieux, 74 miles E. of Brest, was formerly the capital of the duchy of Penthièvre. Hence the word *Gingham* (q.v.). Pop. 8744.

Guinness, SIR BENJAMIN LEE, Bart. (1798–1868), was a member of the great brewing firm in Dublin established by Arthur Guinness in 1759. The business, the largest in the world, was made a limited liability company in 1886, with a capital of £6,000,000, employs nearly 3000 persons, and its premises cover 42 acres. Sir Benjamin, M.P. for Dublin in 1865–68, and a baronet from 1867, restored St Patrick's cathedral at his own cost (£140,000). His eldest son, Arthur Edward, became Lord Ardilaun in 1880. His third son, EDWARD CECIL, born 10th November 1847, created a baronet in 1885 and a peer (Baron Iveagh) in 1891, placed in the hands of responsible trustees in 1889 the sum of £250,000, to be spent in providing sanitary dwellings for workmen at a low rent, £200,000 to be given to London and the rest to Dublin. The income derived from the use of the capital sum is to be devoted to the same purpose.

Guipuzcoa, the smallest but the most densely peopled of the Basque provinces on the Bay of Biscay. The mountains are wooded, the climate good, minerals are largely produced, and there is a good deal of manufacturing industry—soap, pianos, carriages, carpets, iron, paper. The capital is San Sebastian. Area, 728 sq. m.; pop. (1887) 181,856. For the people, see BASQUES.

Guisborough, a market-town of the North Riding of Yorkshire, 9 miles by rail ESE. of Middlesborough, lies at the foot of the Cleveland Hills, in the midst of the iron-mining district. The earliest alum-works in England were established here about the year 1600. Here too are the remains of a priory built in 1119 by Robert de Brus, and at the time of the Reformation one of the wealthiest monastic institutions in the kingdom. Pop. (1851) 2062; (1881) 6616; (1891) 5623.

Guiscard, ROBERT, Duke of Apulia and Calabria, the sixth of the twelve sons of Tancred de Hauteville, was born near Coutances in Normandy about 1015. Following in the wake of his elder brothers, he won great renown in south Italy as a soldier, and after the death of William and Humphrey was proclaimed Count of Apulia. Guiscard next captured Reggio and Cosenza (1060), and thus conquered Calabria, in the possession of which he was confirmed by Pope Nicholas II. Robert now became the pope's champion, and along with his younger brother Roger waged incessant war against Greeks and Saracens in south Italy and Sicily, both of which gradually fell under their arms, the latter being, however, given to Roger as count. The closing years of Robert's life were occupied in fighting against Alexius Comnenus, who had deposed Michael VII. from the throne of Constantinople, Robert being drawn into the quarrel from the fact that he had married his daughter to Michael's heir. Having sent his son Bohemond (q.v.) to reduce Corfu, he himself gained a brilliant victory over Alexius at Durazzo (1081), captured that city (1082), and then marched through Epirus towards Constantinople, when he received information that the Emperor Henry IV. had made an inroad into Italy. He immediately hastened back, compelled Henry to retreat, and liberated the pope, who was besieged in the castle of St Angelo (1084). Then, having returned to Epirus, he defeated the Greeks in several engagements, took possession of some islands in the Archipelago, and was on the point of advancing a second time to Constantinople, when he died suddenly in Cephalonia, 17th July 1085. See works on the Normans in Europe by A. H. Johnson (1877) and T. W. Barlow (1886).

Guise, a town of the French department of Aisne, on the Oise, 25 miles by rail ENE. of St Quentin. Within the town are the ruins of a castle, from which the famous Dukes of Guise derived their title. Guise is now a place of considerable industrial activity, with woollen and cotton manufactures, and a large foundry (800 hands) for manufacturing cooking and heating stoves. The ironworks are conducted on a profit-sharing scheme; and the workmen are provided with dwellings on the associated plan. This *Familistère*, of which the first portion was erected by the initiator of the experiment, M. Godin, in 1859–60, has cost about £80,000, and provides accommodation for 2000 persons. Within the buildings are a café, theatre, nursery, schools, covered playgrounds, a co-operative store, and a library and reading-room. Pop. (1872) 5651; (1891) 8153.

Guise, the name of a branch of the ducal family of Lorraine, which it derives from the town of Guise, in the department of Aisne.

CLAUDE OF LORRAINE, first Duke of Guise, was the fifth son of René II., Duke of Lorraine, and was born at the château of Condé, October 20, 1496. Attaching himself to Francis I., he fought with distinction at Marignano in 1515; but after that campaign remained at home to defend France against the English and Germans (1522–23). During the captivity of Francis I., after Pavia, Claude of Guise suppressed the peasant revolt in Lorraine (1527), for which Francis, after his return home, created him Duke of Guise. In his later years he held himself aloof from public life; he died 12th April 1550.

His daughter Mary, usually spoken of in history as Mary of Lorraine, was born November 22, 1515, and in 1538 became the wife of James V. of Scotland. By his death in 1542, she was left a widow with one child, Mary, Queen of Scots. Under the regency of Arran which followed, war broke out between England and Scotland, partly on account of the claims which Henry VIII. made with regard to the infant Mary's marriage, and partly on religious grounds. Mary of Lorraine during those years acted with much wisdom and moderation; but after her own accession to the regency in 1554, she allowed the Guises too much to influence her policy, the result being that the Protestant nobles combined against her in 1559. This rebellion, which she was assisted by French troops to repress, continued almost to the time of her death, which took place in Edinburgh Castle, 10th June 1560. But before her death she was reconciled to her nobles.

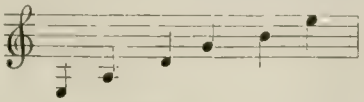
FRANCIS, second Duke of Guise, son of the first duke, was born at Bar, February 17, 1519, and became one of the greatest generals of France. At the siege of Boulogne (1545) he gained the nickname of Balafré from a severe wound in his face. Seven years later he held Metz gloriously against Charles V. of Germany, and thus prevented an invasion of France. He added to his reputation at Renti (1554), fighting against the troops of Charles

V., and in 1556 took command of the expedition against Naples. Recalled thence in the following year to defend the northern frontier against the English, he took Calais (1558) and other towns, and brought about the treaty of Cateau Cambrésis (1559). He and his brother Charles, the cardinal (1525–74), probably the most capable man of the Guises, who afterwards played a prominent part at the Council of Trent, then managed to possess themselves of all real power during the reign of the weak King Francis II. Putting themselves at the head of the Roman Catholic opposition to the Reformation, they repressed Protestantism with a strong arm. In the war between Huguenots and Catholics Guise and Montmorency won a victory at Dreux (1562), and the former was besieging Orleans when he was assassinated by a Huguenot nobleman, on 18th February 1563. He had a taste for literature, and his memoirs, written by himself, have much historic interest. See his Life by Brisset (1840) and Cauvin (1885).

Henry I., third Duke of Guise, son of Francis, was born December 31, 1550. Filled by the murder of his father with bitter hatred of the Protestants, he fought fiercely against them, at Jarnac (March 1569) and Moncontour (October 1569), and in the same year forced Coligny to raise the siege of Poitiers. He was one of the contrivers of the massacre of St Bartholomew, August 24, 1572, in which he personally made sure that Coligny should be slain; and subsequently he put himself at the head of the Catholic League. He had, however, a greater ambition, that of succeeding to the throne of France, for in respect of real power he was already the equal, or rather superior, of the feeble King Henry III., whose commands he set at nought and whom he so deeply humiliated that the king procured his assassination, on 23d December 1588, at Blois. This duke earned the nickname of Le Balafré ('of the scar') in an encounter with German mercenaries of Condé at Dormans (1575). See his Life by Rénauld (1879).

Henry II., fifth Duke of Guise, the grandson of Henry I., was born at Blois, April 4, 1614. He was destined for the church, and at the age of fifteen became Archbishop of Rheims, but, in 1640, on the death of his elder brother, he succeeded to the dukedom. Having joined the league against Richelieu, he was condemned by the parliament of Paris to capital punishment, but found refuge in Flanders. He put himself at the head of Masaniello's revolt in Naples, as the representative of the Anjou family, but was taken prisoner by the Spanish forces (1647) and carried to Madrid, where he remained five years. After another fruitless attempt to win Naples (1654), he settled at Paris and lived the life of a courtier, dying in June 1664 without descendants. His *Mémoires* (2 vols. Paris, 1669) were written partly by Count Raymond of Modena and partly by his secretary, St Yon. The direct line of the house became extinct on the death of François Joseph (1675), the seventh duke, and grandson of Henry II.'s brother Louis. See Forneron, *Les Ducs de Guise* (2d ed. 1893).

Guitar (Lat. *cithara*, Gr. *kithara*, 'a lyre or lute'), a musical stringed instrument, somewhat like the lute, particularly well adapted for accompanying the human voice, and much esteemed in Spain and Italy. It was first introduced into the former country from the East by the Moors. It has six strings, the notation of which is as follows:



but which sound an octave lower; and the sound is produced by the fingers of the right hand twitching the strings, while the fingers of the left hand make the notes of the music on the finger-board, which has frets across it. The three highest strings of the guitar are always of gut, and the three lowest are of silk spun over with silvered wire. The greatest virtuosi on the guitar have been Giuliani, Sor, Zoechi, Stoll, and Horetzsky.

Guizot, François Pierre Guillaume, historian and statesman, was born at Nîmes, October 4, 1787, of middle-class Huguenot parentage. His father, although a Liberal, was guillotined, April 8, 1794, whereupon his mother removed with him to Geneva. There he was carefully educated, being taught among other things the trade of a carpenter, in accordance probably with Rousseau's theories. In 1805 he went to Paris to study law. He soon drifted into literature; and it was a review of Chateaubriand's *Martyrs* (1809) that brought him under the notice of the dictator of Parisian literary society. In the same year appeared Guizot's *Nouveau Dictionnaire des Synonymes*, in 1811 an essay on the fine arts; and in 1812 the final literary bent of his mind showed itself in a translation of Gibbon. That same year he married the first of his three wives, Mdlle. de Meulan (1773–1827), editor of *Le Publiciste*, to which he had been a contributor. Shortly afterwards he was chosen professor of Modern History in the University of France. Guizot was, however, a decided opponent of the Napoleonic *régime*, and it was not till 1814, after its fall, that he became secretary-general of the ministry of the Interior. This office he exchanged after the Hundred Days for the secretary-generalship of the ministry of Justice, and in 1816 for the general directorship of the departmental and communal administration, being at the same time made a councillor of state. As a *doctrinaire* or constitutional Liberal, he found himself out of sympathy with the reactionary policy of the Bourbons. So pronounced was his opposition that in 1821 he was deprived of his public appointments, and four years later interdicted even from lecturing on history. He threw himself once again into literature. In conjunction with some friends he published *Mémoires relatifs à l'Histoire de France jusqu'au 13me Siècle* (31 vols.), and *Mémoires relatifs à la Révolution d'Angleterre* (26 vols.). He also edited translations of Shakespeare and Hallam, and commenced his *Histoire de la Révolution d'Angleterre*. Having in 1828 been restored to his chair, he lectured on the history of civilisation in Europe, and more particularly in France. These lectures, published as *Cours d'Histoire Moderne*, finally established his reputation as one of the first historians of his day.

The time had now come for Guizot to take a more active part in politics. In 1830 he was returned to the Chamber of Deputies for Lisieux, at once became a prominent member of the Opposition, and, although no orator, aided indirectly in bringing about the Revolution of July, which placed Louis-Philippe on the throne. Minister first of the Interior, and subsequently of Public Instruction, he signalised his occupancy of the latter congenial office by establishing a system of primary schools throughout France, giving an impulse to secondary and university education, and reviving the Académie des Sciences Morales et Politiques. In 1840 Guizot, then temporarily in alliance with his leading parliamentary rival, Thiers, came to London as French ambassador, and was received with great respect, on account of his reputation and the interest he had shown in English history. But, unfortunately, at this time the relations between Great Britain and France were strained in consequence of the Syrian question, and Guizot was, not quite accurately, looked upon by Melbourne

and Palmerston as the mouth piece of the policy of Thiers. 'He was always,' in Melbourne's opinion, says Melbourne's biographer, 'what Talleyrand from the first pronounced him to be—*un intrigant austere*.' Fortunately for Guizot he did not hold the embassy long. Thiers's belligerent policy alarmed Louis Philippe into virtually dismissing him. Guizot was summoned to take his place, and till the end of Louis-Philippe's reign was his chief adviser, although it was not till 1847 that he became prime minister. In the early years of his term of power Guizot was undoubtedly successful; his chief aim, like his master's, peace.

When, after the fall of Peel, Palmerston once more obtained the control of British foreign policy, Guizot, by way of checkmating him, plunged into the intrigue which resulted in the 'Spanish Marriages.' This intrigue was totally indefensible, and the indecency of the central incident in it—the forcing of the young queen of Spain into a marriage with a disreputable and intellectually contemptible kinsman—revolted the conscience of Europe, and greatly injured Guizot's reputation. It alienated France from Great Britain, and compelled Guizot to fall back for sympathy on the reactionary forces in Europe, whose hope at this time was Austria. He also relapsed into reactionary methods of government at home, allowed the finances to drift into confusion, and resisted the rising demand for parliamentary reform; whilst, although personally pure, his administration became notorious for scandalous jobs.

With the fall of Louis-Philippe in February 1848 Guizot's active political career really came to an end. He escaped to London, where he was cordially received by old friends, and even by old opponents like Palmerston. In the troubled period which preceded the establishment of the second empire Guizot made efforts both in London and Paris to rally and fuse the monarchical parties of France, but after the *coup d'état* of December 2, 1851, he gave himself up entirely to literature. He completed his works on the Great Rebellion in England, under the titles of *Révolution d'Angleterre* and *Monk, Chute de la République*. He also published *Corneille et son Temps*, and *Shakspeare et son Temps* in 1852; *Mémoires pour servir a l'Histoire de mon Temps*—an explanation of, but certainly not an apology for his policy—in 1858; *Mélanges Biographiques et Littéraires* in 1868; and *Mélanges Politiques et Historiques* in 1869. His *Vie, Correspondance, et Ecrits de Washington* (1839–40) was commissioned by the United States government. Guizot took a keen interest in theological and ethical speculation, and for a long time his voice was supreme in the consistory of the Protestant church in Paris. His excursions into other fields than those of history and politics bore fruit in *Méditations et Études Morales* (1852), and *Méditations sur l'État actuel de la Religion Chrétienne* (1865). His *Histoire de France racontée a mes petits Enfants* was completed and published by his daughter, Madame Guizot de Witt (5 vols. 1870–75).

During the second empire Guizot lived tranquilly in retirement, chiefly at his residence of Val Richer, near Lisieux, in Normandy. On January 19, 1870, he made his first political appearance in public since 1848 by attending a reception given by the third Napoleon's 'Liberal' minister, M. Ollivier. He followed with a painful interest the fortunes of his country in the war with Germany. He approved of the conduct of the Government of National Defence in deciding to carry on war *à outrance*. In a letter to the *Times* on the subject, he mentioned the fact of his having four sons on the ramparts. The veteran statesman survived for more than three years the greatest humiliation his country had ever suffered, dying September 12, 1874.

That Guizot was a man of high personal character, that he led a simple life, and that he despised wealth are beyond doubt. He was a patriot also, according to his lights; if at one period he intrigued abroad and at another connived at corruption at home, he did it for the aggrandisement of his country, not for his own advantage. It must be admitted, however, that constitutional pedantry, obstinacy, and self-sufficiency prevented him from being a great, in the sense of an accommodating and far-seeing politician. As a historian he was painstaking and, on the whole, accurate, but he was not brilliant. Altogether Guizot, though not a great man, was a large and important figure in the history of France and of his time.

The leading authorities on the life of Guizot are his own Memoirs, and *Guizot in Private Life* by his daughter, Madame de Witt (Eng. trans. 1880); Jules Simon, *Thiers, Guizot, Rémusat* (1885); Thureau-Dangin, *La Monarchie de Juillet* (1889); and small biographies by Crozal (1893) and Bardoux (1894). See also Evelyn Ashley's *Life of Viscount Palmerston* (1876), Torrens's *Memoirs of Lord Melbourne* (1878), and Spencer Walpole's *Life of Lord John Russell* (1889).

Gujarat, or GUZERAT, the northern maritime province of Bombay, has, in the narrower sense, an area of 10,296 sq. m., and a pop. (1891) of 3,098,197. In its widest sense on the other hand (with Kathiawar) it has an area of over 70,000 sq. m., and a pop. of 10,000,000. Within the wider limits lie the British districts of Surat, Broach, Kaira, Panch Mahals, and Ahmadabad, the territories of the Gaekwar of Baroda (q.v.), and numerous petty native states. Of these last 180 are on the peninsula of Kathiawar, which projects into the Arabian Sea to the north of the Gulf of Cambay. Gujarati is one of the seven main Aryan vernacular languages of India (q.v.). See also GUJRAT.

Gujranwala, chief town of Gujranwala district, in the Punjab, 40 miles N. of Lahore, on the Northern Punjab State Railway, lies in a flat plain, is notorious for its bad sanitary condition, and has some local trade and petty manufactures. It was for a time the capital of the Sikh power, and Ranjit Singh was born here. Pop. 23,000.—The *district* has an area of 3017 sq. m., and a pop. of 690,169, three-fourths Mohammedans.

Gujrat, or GUZERAT, the chief town of Gujrat district, in the Punjab, has been left (by a change in the river's course) a few miles north of the present bed of the Chenab, but is a place of some military and political importance, as well as the centre of a considerable trade. It produces cloth and cotton goods, brass vessels and gold inlaid-work, and boots and shoes. Here, in 1849, a decisive battle was fought, which finally broke the Sikh power, and brought the whole Punjab under British rule. Pop. 19,000.—The *district* has an area of 2051 sq. m.; pop. 760,875. See also GUJARAT.

Gulden. See FLORIN.

Gules (*gueules*, the French heraldic term for 'red,' is the plural of *gueule*, 'the mouth,' Lat. *gula*), the term by which the colour red is known in heraldry. See HERALDRY.

Gulf Stream and Oceanic Currents. The Gulf Stream is the best known, the best defined, and the most remarkable of all the ocean currents (see map at ATLANTIC). It derives its name from the Gulf of Mexico, out of which, as a great current of warm water, it flows through the Strait of Florida, along the eastern coast of the United States of America, and is then deflected near the banks of Newfoundland diagonally across

the Atlantic. This great body of warm water indirectly modifies the climate of western Europe, and it is possible to trace its effects as far as the coasts of Spitzbergen and Nova Zembla. It is essential in describing the Gulf Stream to take into consideration the general question of oceanic circulation, and the thermal conditions of the ocean made known from the explorations of the *Challenger*, *Blake*, and other recent expeditions.

The prevailing winds of the globe are determined by the distribution of atmospheric pressure, and the position of barometric maxima and minima are in turn determined by the distribution of land-masses and water-surfaces. The wind blows out of and around high-pressure or anticyclonic areas, and into and around low pressure or cyclonic areas (see ATLANTIC). By comparing the maps of the prevailing winds with those of the oceanic currents, it will be seen that the latter roughly coincide with the winds blowing out of and around the high-pressure areas in the Atlantic and Pacific oceans. There have been many theories to account for oceanic circulation, but recent researches show that all the principal surface currents have their origin in, and are maintained by, the action of the prevailing winds of the globe, modified locally by variations in temperature, density, evaporation, gravity, and rotation of the earth.

The phenomenon of oceanic circulation is to be seen in its simplest form in the westerly wind-driven currents of the trade-wind regions of the Atlantic and Pacific. The heated surface waters of the tropics are there driven to the west, and banked up towards the eastern shores of America, Africa, Asia, and Australia. On the other hand, the cold deep water is drawn up along the western shores of America and Africa to take the place of the surface water driven before the trade-winds. The temperatures of the water towards the western parts of the oceans are thus higher and more uniform to considerable depths below the surface than in the eastern, where they are lower and have a wider range at different seasons or different states of the wind. The writer has even measured this effect of the wind in Loch Ness in Scotland; he found the cold water from the bottom drawn to the surface in the course of a few hours, and the warm surface water banked up to the north end of the loch, during a southerly gale. Recent observations show that similar effects are produced in the great oceans during a continuance of winds off shore.

In the Atlantic a large proportion of the waters of the equatorial current are forced into the Caribbean Sea through the passages in the Windward Islands, and then into the Gulf of Mexico, principally through the Yucatan Channel. The amount of accumulation or heaping up of water in the Gulf of Mexico, through the action of the trade-winds, has been measured by the officers of the United States Coast Survey; it has been found that the Atlantic Ocean at Sandy Hook is 3 feet 4 inches lower than the waters of the Gulf of Mexico at the mouth of the Mississippi. This is partly the origin of the force constantly at work to keep up the flow of the Gulf Stream through the Strait of Florida. The stream as it flows through the narrowest part of the strait is 50 miles wide, and has an average depth of 350 fathoms. In the axis of the stream the velocity is four or five knots an hour, two miles an hour or even less along the edges, and probably the same near the bottom. It is estimated to be 150 miles wide off Charleston, and 300 miles wide off Sandy Hook; it then spreads fan-like over the surface of the North Atlantic. Off Cape Hatteras the velocity is about three miles an hour, off the banks of Newfoundland one and a half mile an hour, then the rate slowly merges into that of the north-easterly drift of the Atlantic—four or five miles a day. The mean surface temperature in the straits is 81°·5 F.; off Sandy Hook, 73°·4 F. The average bottom temperature in the strait at 400 fathoms is but 45° F.; off Charleston, at 300 fathoms, 53° F.; and off Sandy Hook, in 200 fathoms, 46°·5 F. The bottom in the strait, and for some distance north on the 'Blake plateau,' appears to be swept by the current so that no fine ooze is allowed to form; but the bottom, where hard, is made up of the remains of surface and bottom-living organisms, often cemented together into nodules and phosphatic concretions. The diagram in the article ATLANTIC shows the distribution of temperature across the Gulf Stream between New York and Bermuda. The Gulf Stream water of the North Atlantic is carried towards the coasts of Europe by the south-west winds; one branch passes on to the coasts of Norway, and another south to the coasts of Spain and Africa. As this water is carried into colder latitudes it sinks on becoming cooled because of its greater density, so that off the coasts of Britain warmer water is found at a depth of three-fourths of a mile than at a like depth off the tropical coast of Africa, where the winds are off shore. While a warm current passes to the Arctic Ocean along the coasts of Norway and Lapland, a cold current from the Arctic comes down the coasts of Greenland, and along the coasts of Labrador and the United States, inside the Gulf Stream, and ultimately sinks beneath it into the deeper parts of the North Atlantic basin. The passage from the green, cold, turbid waters along the American coast into the deep blue, warm waters of the Gulf Stream is sometimes sudden and well marked, and is usually observed by all who sail from the shore seaward.

The winds blow out of and around an area situated in the North Atlantic, between the north of Africa and America, and the surface currents of water also circulate around this area, which is known as the Sargasso Sea. Here are found immense banks of floating Gulfweed (q.v.), covered with peculiar species of animals: Crustaceans, Polyzoa, Annelids, Molluscs, Hydroids, and Fishes, all the same colour as the weed, presenting remarkable examples of protective resemblance.

A very similar, but not such a well-defined or constant stream as the Atlantic one, is found in the North Pacific, and is known as the Kuro Siwo ('Black Stream') or Japan Stream. On approaching Japan in April from the south the *Challenger* found a belt of water running to the eastward at the rate of three miles per hour. In this stream the temperature changed from 63° to 68° F. suddenly several times without any alteration in the rate of the current. In June no current was found 30 to 40 miles from the coast, but close to the south coast of the main island there was a northward current of two miles per hour and a mean temperature of 72°·5 F. Alternating bands of cold and warm water were also found by the *Challenger* in the Gulf Stream near its shore edge. The origin of these alternate belts of water in the Japan Stream is probably due to the monsoons. The northern equatorial current striking against the eastern side of the Philippine Islands is, as is well known, diverted to the northward, along the eastern side of Formosa, after passing which it appears gradually to lose its distinctive character. During the north-east monsoon a cold surface current is running to the southward from the Japan and Yellow seas. It appears therefore highly probable that the equatorial current, instead of losing itself as is supposed, when it meets with the cold water from the Japan and Yellow seas, is diverted to the eastward along with a cold northerly current, the two running together side by side without intermingling their waters. When the north-east monsoon ceases the current

from the Japan and Yellow seas also ceases, which causes the slackness of the Kuro Siwo, south of the main island, in June, as it is then only due to the equatorial current. Later on, in July and August, when it is further augmented by the surface drift from the China Sea in the south-west monsoon, it runs again with great rapidity, and is wholly a warm current. These peculiar effects are probably not experienced to the eastward of the meridian of 140° E.; there apparently the stream is always a warm one. The current that runs from the Arctic Ocean through Behring Strait is insignificant compared with the Arctic currents of the Atlantic. There is an ill-defined Sargasso Sea in the North Pacific, in some respects resembling that of the North Atlantic. The surface currents in the Indian Ocean are, as is well known, changed with the shifting of the monsoons.

From the *Challenger* observations it appears to be proved that the dense warm equatorial waters which pass along the eastern shores of South America, Africa, and Australia into the Great Southern Ocean that surrounds the world in latitudes beyond 40° S., become cooled in these latitudes, and sink to the bottom through the other waters on account of their greater density. This water is then drawn slowly north as a great indraught to supply the loss by surface currents and evaporation in the equatorial regions of the Atlantic, Pacific, and Indian oceans. It appears then that by far the larger part of the cold water that fills these great ocean-basins is cooled and sinks to the bottom in about 50° S. lat. A portion of this water seems also to be drawn southward to supply the place of the relatively light though cold surface currents that flow north from the Antarctic in the regions of floating ice. The great bulk of the ocean has a low temperature—below 45° F.; it is ice cold in the Atlantic at the bottom even under the equator. The warm surface water is a relatively thin film, but this film is much deeper towards the western parts of the oceans in the tropics than in the eastern. On the other hand, in the regions of the westerly winds of temperate latitudes the layer of warm water is deeper in the eastern parts of the oceans, as has been already noticed in referring to the deep-water temperatures off Britain and tropical Africa. These facts are clearly shown on the *Challenger* maps, showing the distribution of temperature at 10, 20, 50, 60, 100, and 300 fathoms.

The surface currents may, as we have seen, have a considerable velocity, but there is no evidence that any such currents exist in the deeper waters at the bottom of the ocean; the movements there must be slow and massive. It is true that between oceanic islands and in positions like the Wyville-Thomson Ridge, between Scotland and the Faroe Islands, where the tidal wave is confined, the ridges are swept by currents at a great depth; but these are exceptional cases. In the open ocean the temperature decreases with increase of depth, except in the Arctic or Antarctic, where there is melting ice on the surface. In enclosed seas, like the Mediterranean, Caribbean Sea, Gulf of Mexico, Sulu Sea, and many others, there is a large body of water at the bottom of a nearly uniform temperature; the depth at which this uniform temperature is reached depends on the height of the ridges cutting enclosed seas off from general ocean circulation. The deeper water in these can only be renewed by vertical currents set in motion by the winds or by convection currents. The direct influence of ocean currents on climate is undoubtedly great, but this influence is most marked by the indirect effects of the prevailing winds blowing from off these currents towards the land, carrying with them heat and moisture.

Gulfweed (*Sargassum*), a genus of seaweeds (Algæ) of the sub-order Fucaceæ, of which two species (*S. vulgare* and *S. bacciferum*) are found floating in immense quantities in some parts of the Atlantic, Pacific, and Indian oceans. They are tropical plants, although sometimes carried by winds and currents to the British coasts. The frond is very long, and is furnished with distinct, stalked, nerved leaves, and simple axillary stalked air-vessels. The receptacles are linear, in small axillary clusters or racemes. The trivial name *bacciferum*, applied to one of the species, is derived from the berry-like appearance of the air-vessels. The gulfweed has only been found floating, but there is reason to think that it is at first attached to the bottom of comparatively shallow parts of the sea. It floats in large fields, or more frequently in long yellow lines in the direction of the wind. In crossing the Atlantic, its presence is regarded as a sure indication of the Gulf Stream, by which it is wafted northward and eastward. Where the Gulf Stream is deflected from the banks of Newfoundland eastward, and sends off its more southern branch towards the Azores, is situated the *Sargasso Sea*, 'that great bank of weeds, which so vividly occupied the imagination of Christopher Columbus, and which Oviedo calls the seaweed meadows' (Humboldt). The quantity of floating seaweed is often such as to impede the progress of ships. Multitudes of small marine animals accompany it, with fishes ready to prey on them.—The gulfweed is eaten in China; and in other parts of the East also it is used in salads and as a pickle.

Gull (*Larus*), a genus of web-footed birds belonging to the Laridæ, a family of long-winged sea-birds having the longitudinal nostrils placed laterally and not covered by a cere, the three anterior toes completely webbed, the hind-toe, when present, small and not touching the ground. The family includes the Scissor-bills or Skimmers (Rhynchopidæ), the Terns or Sea-swallows (Sterninæ), and the true Gulls (Larinæ). The true gulls are of less slender build than their nearest allies, the Terns; their wings are not quite so long and pointed, and they have the bill more hooked. The most important genera are Stercorarius, the voracious and predatory Skuas; Rissa, the Kittiwakes; Xema, the fork-tailed Gulls; and Larus.

The genus Larus comprises sixty species, cosmopolitan in their distribution, and includes many of the larger gulls and most of those common in Great Britain. The prevailing colour is 'white, with a gray mantle varying in shade from the most delicate pearl gray to a dark blackish slate or nearly black,' and there are often black markings about the head, which, however, vary in different seasons. The two sexes are usually almost alike in colour, but the young are dusky and brownish and have the bill dark, while in adults the bill, legs, and feet are bright red or orange. The legs are very powerful, and are placed well forward so that the body is carried horizontally, the bill is stout and curved, with a prominent angle on the lower part and a corresponding swelling on the upper. Though most gulls are marine, they frequent, and even breed by inland lakes not far from the sea, and large flocks of them may often be seen following the plough eagerly picking up the worms and grubs. They are very voracious and will eat almost anything, but feed chiefly on fish and molluscs. To break the shells of the molluscs they sometimes carry them high into the air and drop them upon a rock. Audubon tells of a gull observed by him which, when the shell did not break the first time, carried it a second time higher, and a third time higher still. Some of the larger species—e.g. the Great Black-backed Gull (*L. marinus*), prey even upon the eider-duck and other wild fowl, and very many

steal the eggs of other birds. Many of the species are migratory, and all are powerful of wing and fly with apparent ease against a storm, during which, however, they never soar so high as in fine weather. Their keenness of vision is remarkable, as must have been observed by every one who has watched them following in the wake of a steamer, and noted the distance from which they see even a small fragment thrown on the water, and the unerring precision with which they dart down upon it.

Heads of Various Species of Gulls:
1, Great Black-backed (young); 2, Black-headed; 3, Kittiwake; 4, Lesser Black-backed; 5, Herring Gull.

Gulls often nest together in large numbers, and to dwellers by the sea a 'gullery,' with its busy life and incessant noise of screaming and quarrelling, is a not unfamiliar sight. The characteristic cry of many gulls is well suggested in the old name of 'Sea-mews.'

The most widely distributed British species is the Herring Gull (*L. argentatus*), which breeds on precipitous cliffs or isolated rocks all round the coast. The nest is made of grass and is usually placed on a ledge of rock, but sometimes on the ground; and Howard Saunders says that in North America, when the bird has been repeatedly plundered by fishermen, it even nests in trees. The eggs, usually three in number, are light brown, green, or pale blue, mottled with a darker shade. The male bird measures 22 to 24 inches, the female is slightly smaller; the gray of the back and wings is lighter than in most species, and on this account it is often called the Silvery Gull. The Common Gull (*L. canus*) is only a winter visitor to England and Wales, but breeds abundantly on the Scottish coasts and fresh-water lochs, in the Hebrides, and in Orkney and Shetland. It lays three eggs, breeding in colonies on grassy islands and slopes not far above the level of the sea, and seldom going far from land. Its average length is 18 inches. The Great Black-backed Gull (*L. marinus*) rarely breeds in England, though large flocks may be seen at some seasons. In Scotland, particularly in the Outer Hebrides, it is more plentiful, though by no means common. The Lesser Black-backed Gull (*L. fuscus*) is very abundant in the marshes of Cumberland, and nests also in Devon, Cornwall, and throughout Scotland. Its plumage is white in summer except on the mantle, where it is dark gray or black. The Black-headed Gull (*L. ridibundus*) is the commonest species in Ireland, and is plentiful on the flatter portions of the English and Scottish shores. It has a dark-brown hood in summer which disappears in winter. The Glaucous Gull, or Burgomaster (*L. glaucus*), and the Iceland Gull (*L. leucopterus*), visit Britain occasionally in cold weather. One specimen of Ross's Gull (*Rhodostethia rosea*) was shot in Yorkshire in 1846. Nothing is known of the breeding habits of this rare and beautiful Arctic species, and only twenty-three examples had been recorded previous to 1881–82, when it was seen in large flocks off Point Barrow in Alaska. About thirty specimens of another truly Arctic species, the Ivory Gull (*Pagophila eburnea*), have been taken in Britain at various times. In North America gulls are very plentiful. The Great Black-backed Gull (*L. marinus*) and Herring Gull (*L. argentatus*) are common in the north-east, while the Common Gull is represented by two closely related species (*L. brachyrhyncus* and *L. delawarensis*). The Mackerel Gull (*Hydrocolœus scopulinus*) of New Zealand may often be seen in attendance on the long-billed oyster-catcher as he digs in the soft sand for blue crabs and other delicacies, waiting quietly until something is discovered, then flapping his wings and making a dash at it. Even if the oyster-catcher succeed in flying off with his prize he is inevitably overtaken and compelled to give it up to the swifter and stronger gull.

The Great Skua (*Stercorarius catarrhactes*), which breeds in the Shetlands, and is occasionally seen on the coasts or fishing-grounds farther south, is a splendid example of a robber gull, deriving its food chiefly by victimising or even killing other sea-fowl. It measures about 2 feet in length; the plumage is predominantly brown, 'with white bases to the quills conspicuous in flight;' the cry, as the name suggests, is *skui, skui;* the nest is a cavity in the moss and heather of the highest moorlands, and is prepared in the later half of May; the eggs (never more than two) are olive-brown. Three other species of Skua are recorded among British birds.

The Kittiwake (*Rissa tridactyla*) is a very common bird on British coasts, and is elsewhere widely distributed. As the specific name suggests, the hind-toe has disappeared; the length of the body is about 15 inches; white predominates in the plumage, but the upper surface is gray, and there is some black on the wing. The kittiwakes feed on fish and other marine animals, make nests of seaweed and flotsam on the rocky ledges, lay two or three eggs 'from grayish-white to olive-buff, blotched and zoned with ash-gray and rich brown.' Howard Saunders notes that as the eggs are seldom laid until the later part of May, many of the young can scarcely fly or are still in the nest by 1st August, when the Sea Birds Protection Act leaves them to be slaughtered in thousands to provide plumes for ladies' hats.

The flesh of gulls is rank and coarse, but that of the young birds is salted for winter use on many northern coasts. The eggs are much sought after, and it is stated that from 40,000 to 50,000 eggs of the herring gull are taken for food, in a single season, from the island of Sylt alone. See Howard Saunders, 'The Larinæ or Gulls,' in *Proc. Zool. Soc.* (1878); and his and other manuals of British birds.

Gull, Sir William Withey, physician, was born 31st December 1816, at Thorpe-le-Soken, in Essex. He studied at Guy's Hospital, and graduated M.B. at London University in 1841. Six years later he was made professor of Physiology at the Royal Institution, a post which he held for only two years. About the same time (1847) he became physician and lecturer at Guy's Hospital, his specialty being clinical practice. For his treatment of the Prince of Wales in 1871 he received a baronetcy, and was appointed physician-extra-

ordinary to the Queen. He became a Fellow of the Royal College of Physicians (1848) and of several other medical and learned societies. He died 29th January 1890. Sir W. W. Gull published numerous papers and addresses, as *Reports on Epidemic Cholera* (with Dr W. Baly) in 1854; *Gulstonian Lectures on Paralysis*; the Hunterian oration in 1861 and the Harveian in 1870; and *Alcohol as a Medicine and as a Beverage* (1878). His collected works were edited for the New Sydenham Society by Dr Acland in 1893 and following years.

Gullet. See DIGESTION, Vol. IV., p. 814.

Gulliver's Travels. See SWIFT.

Gum, a general term applied to certain exudations from trees and plants, which are very different in their chemical characters and their general properties. There are, however, three classes of gums which may be more particularly referred to — viz. those containing arabin, those containing bassorin, and gum resins.

(1) *Gums containing arabin* are best represented by gum-arabic, the ordinary gum of the shops. This substance is found as an exudation on the bark of the *Acacia Senegal*, a tree of some 20 feet in height, growing abundantly in western Africa. According to the care taken in collecting it, it ranges from the pure white or colourless gum of Kordofan to the dark-reddish varieties imported from Senegal. Chemically these are absolutely identical, and therefore a single description will suffice. It occurs in irregular lumps, somewhat spherical or vermicular (as in Gum-Senegal). It is brittle, and shows a glassy fracture. It dissolves readily in water, forming a clear, viscid, adhesive solution; but it is insoluble in strong alcohol, glycerine, ether, oils, or chloroform. The addition of alcohol to a watery solution throws down a precipitate of arabin, if a few drops of hydrochloric acid have previously been added.

Medicinally it has very slight remedial powers, but it is largely used in prescriptions for the purpose of suspending insoluble substances in mixtures. The finer varieties, owing to their cost, are rarely found outside the druggist's shop; but in the manufacture of confections and in the arts large quantities of the cheaper kinds are employed. These are known under different names, indicating the district from which they are imported. The chief are: Senegal gum, found in large firm reddish masses; Suakin gum or Talka gum, forming dull opaque-looking tears, colourless or brownish; and Morocco or Barbary gum. Cape gum is derived from the *Acacia horrida*, a native of Cape Colony, while Wattle gum is a very adhesive variety obtained from Australia. East Indian gum is an African product, being simply imported into Bombay from the Red Sea.

(2) *Gums containing Bassorin.* The chief of these, Tragacanth, is obtained from various species of Astragalus, low spiny bushes, natives of Asia Minor and Persia. When the stem of one of these plants is cut transversely it will be found that the space usually occupied by the pith has the appearance of a translucent gummy mass, which the microscope shows to possess the structure of an ordinary pith. If incisions are made in the bark, this semi-solid exudes under pressure, and, according to the nature of the incision forms flattened wing-like masses, nodules or worm-like pieces. The finest variety is known as Flake-Tragacanth, consisting of flakes 1 to 3 inches long by 1 inch in breadth. The surface is marked by wavy lines and the flakes are much contorted. Tragacanth is translucent, white and without lustre, somewhat flexible, and not brittle, and with little taste or smell. When placed in water it swells, absorbing fifty times its weight of that liquid, and form ing a thick mucilage. It has no active medicinal properties; but it is much used for firming pill masses and lozenges. It enters into many emulsions, for instance, that of cod-liver oil, and it is sometimes employed as a stiffener for the hair. It is used as a stiffening material for various textile fabrics, and is much valued for this purpose, where it is not desired to give gloss to the material.

Besides these true gums, there are (3) *the gum-resins.* In general terms these consist of certain resins soluble in alcohol, and of the true gum, so that it requires both water and alcohol to dissolve them entirely. They are chiefly used in medicine and perfumery, and may be said to form a connecting link between the true gums and the true resins, commercially speaking. The principal are: (1) Gum-Ammoniacum (see AMMONIACUM), (2) Gum-Asafœtida (see ASAFŒTIDA), (3) Gum-Benzoin (see BENZOIN), (4) Gum Galbanum (see GALBANUM), (5) Gum-Gamboge (see GAMBOGE), (6) Gum-Myrrh (see MYRRH), (7) Gum-Scammony (see SCAMMONY). There are many other gums known; but these are the ones most used in the arts and medicine. Many also of the true resins, as copal, anime, &c., are called gums, but they are strictly resins. See RESINS.

Gum-substitutes are manufactured from various forms of starch, either by baking, roasting or chemical treatment, so as to convert the starch into Dextrine (q.v). They are made on a very extensive scale, and are largely employed in dressing calicoes and other fabrics, also as a substitute for the more expensive gums in gumming-paper, as in the case of postage-stamps and labels, which are made adhesive by dextrine. For this and some other purposes, the *gum-substitutes* are superior to the real gums, as they are easily dissolved, and can be spread more equally over a smooth surface. For the chewing-gum in use in the United States, see CHEWING-GUM; and for gum-trees, see EUCALYPTUS, TUPELO, and LIQUIDAMBAR.

Gumbinnen, a thriving town of East Prussia, 72 miles by rail E. of Königsberg. Dating from 1724, it owes its prosperity to the settlement eight years later here of many Protestant Salzburgers. There are machine-works, &c. Pop. 10,206.

Gum-boil, an Abscess (q.v.) near the root of a tooth, and usually discharging itself towards the mucous membrane of the gum, but sometimes making its way more deeply towards the skin of the face, and if allowed to burst there causing considerable deformity. Gum-boil should be treated, in the first instance, by protection against cold and external injury, and free washing of the mouth with hot water; but as soon as the presence of matter can be ascertained, it is usually a good practice to give vent to it by a pretty free incision. Complete cure follows the removal of the tooth at the root of which the inflammation has begun; if it be left the disease is apt to recur. If the abscess threaten to burst through the skin, extraction of the tooth is imperative. See TEETH.

Gumming (in vegetable pathology *Gummosis*), a disease which attacks the plum, cherry, peach, and other stone fruit-trees, often proving fatal to the limbs attacked, and ultimately also to the whole tree in virulent cases. Recent observations seem to prove that the cause of the disease is a fungus named *Coryneum Beijerinckii*. The mycelium of the fungus develops a ferment which transforms the cell-walls, starch granules, and other contents of the cells into gum. While in some cases the mycelium is obviously the exciting cause, in others the ferment only appears to be the contagious agent. One point seems quite clear—the fungus cannot penetrate sound healthy bark—there must be some wound or abrasion before the

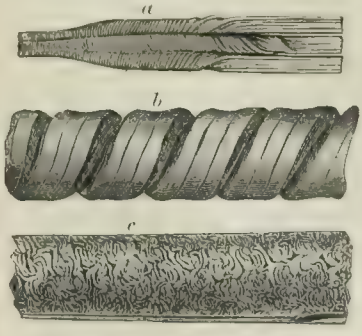
germ-tubes can enter the cellular tissues in which alone they can spread. Unfortunately such injuries occur from many causes in the class of trees named, and probably insects are the chief agents in carrying the contagion from tree to tree. In prescribing remedies, those that are preventive are obviously best. Wounds as soon as they are observed should be coated with a thick paste of quicklime or coal-tar. Gummed branches should be cut away without delay and burned, and the wounds dressed at once with coal-tar.—It is conjectured that Coryneum or some similar fungus is the cause of the disease that produces gum-tragacanth, and probably other gums and gum-resins.

Gumri. See ALEXANDROPOL.

Gumti, a river of India, rises in the North-western Provinces, in a small lake in 28° 37′ N. lat. and 80° 7′ E. long., and, after a sinuous but generally south-easterly course of nearly 500 miles, enters the Ganges 56 miles below Jaunpur. It is navigable by boats of 17 tons for over 400 miles; at Lucknow it is spanned by five bridges, and at Jaunpur by a bridge of sixteen arches.—There is also a Gumti River in Bengal, which joins the Meghna after a course, inclusive of windings, of 66 miles.

Gun. The term gun formerly comprised many varieties of the weapons now more correctly termed Firearms (q.v.), and is still applied in a general sense to Cannon (q.v.) and large ordnance, also to quick-firing or Machine Guns (q.v.); but it is now more specially held to signify the sporting gun as distinguished from the military Rifle (q.v.). The modern shot-gun is invariably breech-loading, and usually upon the 'drop-down' principle (see BREECH-LOADING). The manufacture of shot-guns is an important British industry, and one of the processes of manufacture—barrel-welding—is sufficiently interesting to warrant descriptive details. The other processes, some eighteen or twenty in number, call only for the skill of the trained workman.

Shot-gun barrels are generally hand-forged from a rod of special material which is usually composed of iron of two distinct varieties, or of iron and steel. It is necessary that one of the metals be softer than the other; and the greater the proportion of the harder metal, and the harder the quality of the softer metal, the better will be the quality of the welded barrel. Some varieties of gun-iron contain 70 per cent. of steel; in others a good quality and an inferior quality of iron are used together, and no steel enters into the composition. The rod of gun-iron is built up of alternate layers of the hard and soft metals, and in the manufacture of a Damascus barrel this rod must be twisted upon itself before it is welded side by side to one or more rods, or welded into a barrel. These twisted rods are drawn out between rolls into a flattened rod or 'riband' of metal, the riband being composed of one, two, three, or more twisted rods according to the quality of the barrel or the *fineness* of figure desired. The Belgian welders are more expert than the British in making the finest figured barrels, putting as many as six differently twisted rods together to form a single riband; but Belgian barrels are not so hard as the English, and are generally considered to be inferior to the best Birmingham hand-welded barrels. The welder, having prepared his iron and received it from the mill rolled down to the proper size, proceeds to form the barrel by twisting the riband upon a mandril, just as one would cover a whip-stock with a narrow strip of leather. This coil has then to be heated, a few inches at a time, and the edges welded to each other, the result being a tube four times heavier than it will weigh when finished by boring, grinding, and filing, which are the next three processes through which the barrel must pass. In double shot-guns the two tubes to form the barrels are brazed together for a few inches at the breech end, and soldered to each other and to the two ribs and 'packing' which unite them throughout their entire length. The breech actions are fitted to the barrels, the lock-work and bolting-mechanism adjusted, and the gun is ready for the stocker; he roughly fashions the piece of walnut to which the ironwork is secured by the 'screwer,' who passes the gun on to the 'finisher' to prepare for its final embellishments, in which are comprised the processes of polishing, engraving, hardening, blueing, and tempering. The barrels when finely polished are treated with acid, which rusts the surface of the metals of which they are composed, and eating more readily into the softer metal turns it a darker colour. This process, termed 'browning,' occupies several days, and when successful shows clearly the damascening or curls of fibre obtained by twisting the gun-iron rods in the earliest stage. A barrel not showing such curls would be termed a 'scelp' barrel if it were a twisted welded barrel, but if of one uniform colour, unbroken by regular markings, it would probably be composed of plain iron or steel only.



a, gun-barrel iron, twisted and laid into a riband; *b*, portion of gun-barrel coil; *c*, portion of silver-steel Damascus barrel.

The superiority of the Damascus barrel to one of best modern steel remains a vexed question. The evidence adduced on behalf of the Damascus is sufficient to prove its superiority over certain qualities of steel, but it is not overwhelming; and it is now generally admitted that steel can be obtained of sufficiently good quality and possessing sufficient strength to withstand any normal strain to which as a shot-gun barrel it may be subjected. The advocates of the welded barrel contend that flaws, which cannot be detected by the eye or by the most searching test, occasionally exist in steel, making it unreliable for use as a gun-barrel. Sir Joseph Whitworth's fluid compressed steel has been used very successfully as a material for shot-gun barrels, but the immunity from flaws which barrels of this steel enjoy is said to result from the careful testing and examination of each individual tube rather than from absolute perfection in the metal itself. The complete and almost perfect heterogeneity of the material of the Damascus barrel produces a homogeneous whole, which, when soundly welded, has no weak spot, and will neither split longitudinally nor break off short as steel barrels have done, but when burst is pulled, as it were, from shred to shred, exhibiting great tenacity in every direction. The steel barrel here referred to is that drilled from a solid rod of best mild steel. Steel barrels drawn from blanks in the same manner as ordinary tubes are inferior to the drilled barrel. Still less reliable are the lap-welded steel barrels in which the two edges of a strip of metal are brought together and welded as it passes at welding heat between the rolls. Cold drawn steel barrels were at one time manufactured, but proved too expensive, and twisted steel barrels are not yet a

commercial success. The standard size of the modern shot gun is 12 bore—i.e. twelve spherical leaden bullets of the same diameter as the interior of the barrel will weigh 1 lb. avoir.; formerly 16 and 20 bores were much in vogue, and 16 bores are still very common in Germany; 10 bores are much used in North America; 8 and 4 bores are used only for wild fowling; and *punt-guns*, guns of from 1-inch to 3-inch bore fitted into shooting punts, are employed for firing from ½ lb. to 4 lb. of shot at a time into flocks of sea-fowl on the coast or in tidal estuaries.

With the exception of the punt-guns, which require special mechanism, guns of all bores are made upon the same principle of breech-loading, and nearly all are more or less choked—i.e. the diameter of the barrel is suddenly lessened near the muzzle, forming a cone which causes the pellets of the charge to fly from the gun more compactly and at an increased velocity. Such is the perfection to which the boring of shot-guns has been brought that a 7-lb. gun may now be expected to send on an average 220 pellets of a charge containing 305 pellets into a circle 30 inches in diameter (or 60 into a 10-inch square) at 40 yards distance, the pellets having an average velocity at the muzzle of 840 feet per second, and a striking force at impact (40 yards) of 1·90 oz.

Shot-guns are now built very much lighter than when breech-loaders first came into general use (1865); shorter barrels are used without loss of shooting power or appreciable increase in the volume of the recoil. Smokeless explosives are in general use all the world over for shot-guns, and the results of the slightest variation in the charge or quality of the powder, or in the size and quantity of the shot, can be ascertained with the greatest scientific accuracy, by means of special instruments found in all leading gun-manufactories. Shot-gun manufacture is a mechanical science as well as a handicraft, and the finest productions of the most renowned gun-makers will always command £50 or even higher prices. Cheap ill-made, ill-fitted, ill regulated guns, shaped by machinery, or still more roughly by hand labour, constitute the shot-gun of commerce, and their value fluctuates with the price of material. The shot-gun of the best class is now so highly perfected that a new departure, whether towards the development of the killing powers of the weapon or elaboration of its mechanism, is undesirable, and, until some radical change in the composition of explosives, or the method of using shot-guns, takes place, no noteworthy improvement upon the existing type of gun can be expected.

Payne-Gallwey (Badminton Lib. 1886); Payne-Gallwey's *The Fowler in Ireland* (1882; Walsh's *Modern Sportsman's Gun and Rifle* (2 vols. 1883–84); General Norton's *American Inventions and Improvements in Breech-loading, Small Arms, Heavy Ordnance, Machine Guns, Magazine Arms, &c.* (New York, 1889).

Gunboat, a small boat or vessel armed with one or more guns of heavy calibre. From its small dimensions, it is capable of running close inshore or up rivers, and from the same cause it has little chance of being hit by a larger vessel at the long range which the carrying power of its guns enables it to maintain. At the outbreak of the Russian war, a large squadron of them was hastily constructed for the British navy for the first time. Their tonnage was small; and their armament usually consisted of one 8-inch gun and one 100-pounder Armstrong gun. Gunboats in their more modern form (like the *Staunch*) are small mastless vessels mounting one large gun in the bow, and propelled by an engine with single or twin screws. The gun is pointed by means of the helm or the screws, and the gunboat is in fact a floating gun-carriage. In the British navy these gunboats carry an armour-piercing gun of 18 tons, on a draught of only 4 feet. But they have been designed to carry 35-ton guns, or heavier. In 1890 there were on the British *Navy List* 114 of these vessels, of which 43 were called third class, and are intended for coast defence. In 1900 there were in the navy 33 torpedo gunboats, the largest form of special torpedo boats. At the beginning of the century the United States had over 250 of these vessels; but the 'gunboat system' was soon abandoned. In 1899 the United States navy possessed 17 gunboats of from 900 to 1400 tons, armed with 4-inch quick-firing guns and light secondary batteries. They are mainly unarmoured, though some have a slight protective deck. Most Continental navies are provided with gunboats of various size and construction.

Gun-carriage is a most important adjunct to every piece of ordnance. It requires to be of great strength in order to resist the shock of discharge, and, in the case of a field-gun carriage, to bear an enormous strain in passing at a rapid pace over broken, uneven, or rocky ground without being unduly heavy or wanting in mobility. A large department, fitted with splendid machinery, in the Royal Arsenal at Woolwich, called the Royal Carriage Department, is charged with this branch of manufacture for the British service, whether naval or military. See CANNON for plates showing several of the numerous patterns, and also MONCRIEFF PITS.

Gun-cotton. There are a very large number of explosive nitro-compounds which may be divided into two main classes—viz. (1) Those containing Nitro-glycerine (q.v.), in which is included the great dynamite class, and (2) those not containing nitro-glycerine. Gun-cotton is an explosive nitro-compound of the latter class, and is by far the most important of the class.

So long ago as 1832 it was discovered by Braconnot that woody fibre and similar substances could be converted into highly combustible bodies by the action of concentrated nitric acid; six years later Pélouze extended this discovery to cotton and other organic substances; he was followed by Dumas, who treated paper in a similar way, and he proposed to make cartridges with paper so treated, the idea being that no residue would be left in the barrel after firing such cartridges. But no practical result followed these discoveries until in 1845 Schönbein, a German chemist, having hit upon the proper mode of treating cotton with nitric and sulphuric acids, announced the discovery of gun-cotton, which he proposed as a substitute for gunpowder. He claimed for it that the advantage it had over gunpowder was that it burned without leaving any residue, and consequently without smoke. He prepared it by immersing carded cotton wool in a mixture of nitric and sulphuric acids, and the equation for its formation may be stated thus:

Cellulose.	Nitric Acid.	Bi-nitrated Cellulose or Gun-cotton	Water.

$$C_6H_{10}O_5 + 3(H.NO_3) = C_6H_7O_2.3(NO_3) + 3(H_2O).$$

It will be observed that no mention is made of sulphuric acid in this equation, the presence of which is, however, essential in the production of gun-cotton, for although it takes no active chemical part in the action, it absorbs the water which is formed by the chemical transformation, and thus

keeps the nitric acid up to its full strength. Schönbein's discovery gave a great impetus to the question, and experiments continued to be made by many eminent chemists in nearly every country in Europe with the idea of utilising the new explosive for military purposes. It was first manufactured in England on a large scale in the year 1847 by Messrs Hall & Son of Faversham; but, in addition to minor accidents, a terrible explosion took place in their works, which created so much distrust that its manufacture in England was discontinued for several years, as the cause of the explosion, with the then imperfect knowledge possessed of the subject, could not be satisfactorily accounted for. The first country to turn Schönbein's discovery to practical account was Austria. General Von Lenk, an Austrian artillery officer, after extensive trials succeeded in greatly improving the method of manufacture, by which means he was enabled to moderate and ensure a uniform rate of combustion of gun-cotton in air; his discovery was considered of so much importance that in the year 1852 several batteries of Austrian artillery were armed with gun-cotton cartridges. But it soon fell into disrepute, not only on account of its unstable nature, but also because it was found that Von Lenk's improvements were of no practical utility when the gun-cotton was confined in the bore of a gun; the great heat generated caused the inflamed gas to penetrate rapidly through the whole cartridge, so that there was little or no retardation in the rate of combustion, and the rapid combustion caused excessive pressure in the bore, besides giving very unequal results when fired.

Since the failure of the Austrian cartridges gun-cotton has not been used as a propelling agent on a large scale. But its utility as a disruptive agent has been enormously increased by the discoveries of Professor Sir Frederick Abel and the late Mr E. O. Brown. Nothing daunted by the failure of the Austrian experiments, nor by the explosion at Messrs Hall's works, Sir Frederick Abel continued his experiments, and he ultimately discovered a method of manufacture whereby not only a complete purification from free acid is assured, but the material is converted into thoroughly compact homogeneous masses. As a result of his experiments the method of manufacture adopted in England may be briefly described as follows: the best white cotton waste alone is employed; this is first thoroughly cleansed from all grease by boiling with alkalies; it is then picked over by hand and all foreign substances removed, after which the fibre is separated and all knots and lumps opened out by passing the cotton waste through a 'teasing' machine; it is then cut into 2-inch lengths, thoroughly dried, and divided into charges weighing 1¼ lb. each, which are kept in air-tight tin boxes till ready for dipping. The acids used in the manufacture of gun-cotton are nitric acid having a specific gravity of 1·52 and sulphuric acid of 1·84 sp. gr.; these are mixed in the proportion of one part by weight of nitric acid to three of sulphuric acid, and allowed to cool down in iron tanks. The mixed acid is run off into the dipping pans into which a 1¼-lb. charge of cotton is immersed and left in for about five minutes, in which time it will have absorbed about 14 lb. of acid. The charge is now allowed to cool down, after which the waste acid is extracted by means of an 'acid-extractor,' and the charge thoroughly washed to remove all the free acid. It is now pulped and pressed under hydraulic presses to one-third its bulk, and moulded into slabs of various sizes and shapes for storing. The method of manufacture as here described is perfectly safe, as the gun-cotton throughout is in a wet state.

The properties of gun-cotton, as compared with gunpowder, are mainly as follows: (1) It can be ignited at a temperature of about 300°, whereas gunpowder requires a temperature of about 600° to ensure ignition; (2) its combustion leaves no solid residue, and is unattended by smoke; (3) the action of gun-cotton is much more rapid than that of gunpowder, and, as has already been pointed out, it is this rapidity of combustion which renders it unsuitable to be used as a propelling agent in cannon; (4) whereas gunpowder is greatly influenced and injuriously affected by moisture, gun-cotton on the contrary is perfectly uninjured, and may be kept for any length of time in water without change. For military purposes this is a most important consideration. Apart from the question of using gun-cotton as a propelling agent, its value for destructive purposes was incontestable, but it was thought to be necessary, in order to develop its full power, that the charge should be strongly confined. Experiments, however, conducted by Mr E. O. Brown clearly demonstrated the fact that compressed gun-cotton could be fully detonated in a totally unconfined state by fulminate of mercury. This discovery was thought to apply to dry gun-cotton only, but Mr Brown continuing his experiments ascertained that wet compressed gun-cotton could be detonated by using a small primer of the dry material. Still further discoveries were made with regard to the detonation of gun-cotton; it was ascertained that detonation, being established at one end of a continuous row of distinct masses of compressed gun-cotton, travels along the whole length of the row, even if a space of half an inch is left between the discs. These discoveries have raised gun-cotton to the highest rank as a military explosive, as the necessity for storing it in a dry state, which is so highly dangerous, is entirely obviated; it is now always stored in a wet state, the gun-cotton containing about 20 per cent. of water, and is packed in air-tight metal cases, so that the necessity for rewetting seldom occurs; in this condition it can be transported with perfect safety.

The discovery with regard to its detonation when in a wet state has led to this material being used as the charge for torpedoes and submarine mines. The first pattern of Whitehead torpedo was 14 feet long and 16 inches in diameter; the speed of the torpedo was 9 knots for 200 yards, and the charge was 118 lb. of compressed wet gun-cotton. Several subsequent patterns of torpedoes have been introduced, the latest being 14 feet long and 14 inches in diameter, and by reducing the charge of gun-cotton to 80 lb. the high speed of 27 knots for 600 yards has been attained. The immense importance of this increased speed can be readily appreciated, as it enables a torpedo to strike the vessel at which it is discharged before she has time to get out of the way. The torpedoes are fired by a striker actuated by a spring which is released on the torpedo striking the side of the ship; the striker is pointed, and penetrates a cap charged with 38 grains of fulminate; this cap is embedded in an 8 oz. disc of dry gun-cotton, enclosed in a hermetically sealed case, and placed as nearly as possible in the centre of the wet gun-cotton charge containing 12 per cent. of water. Gun-cotton is also used as the charge for submarine mines, the charge consisting of from 50 to 500 lb. of wet compressed gun-cotton.

There are various descriptions of marine mines. (1) *Ground mines:* in these the charge is contained in a case of sheet steel, with cast-iron sinkers attached to it to keep it at the bottom of the harbour or river; these mines are fired electrically by observation from the shore when an enemy's ship passes over them. (2) *Buoyant mines:* these are anchored a few feet below the surface of the water by a steel

rope attached to a sunken weight; they are connected with the shore by electric wires; a buoy with a signalling apparatus is attached to the mine, and when a ship strikes a buoy it rings a bell in the signalling room on shore; if the ship is a friendly one it is allowed to pass, but if it is an enemy's ship the mine is fired by electricity and the ship blown up. (3) *Electro-contact mines* these are used only in places where an enemy's ship would pass. When the mine is struck by a passing ship a steel spring or pendulum moves towards the point of impact and thus closes the circuit and fires the mine automatically.

A powder made by the Explosives Company, and generally known under the name of *E.C. Powder*, is another form in which gun-cotton can be used. There are two descriptions of this powder—viz. sporting and rifle powder; they are both essentially granulated gun-cotton, and consist of small rounded granules, the sporting powder being coloured orange with aurine, and the rifle powder yellow with picric acid.

Schultze Powder may be mentioned here as, although not strictly speaking a gun-cotton powder, it belongs to the class of explosive compounds not containing nitro-glycerine. The process of manufacture consists in macerating soft timber from which all resinous and fatty matter has been extracted by chemical means, the residue being pure finely-divided cellulose; this is saturated with nitric and sulphuric acids, and thoroughly purified by washing. The nitro compound thus formed is finely ground and waterproofed, and then sifted into the various sizes of grain required. Schultze powder has been manufactured since about the year 1860, but E.C. is a powder of more recent date. Both these powders are now largely used for sporting purposes. The great advantages they possess over the ordinary black powder are that an equal velocity is obtained with a very much smaller charge, that they do not foul the gun, and that they are nearly smokeless. But against this must be set the disadvantage that under certain conditions the strain on the breech of the gun is greater. But hitherto the results obtained from these powders when used in military firearms are not sufficiently uniform or regular to justify their adoption for military purposes. There can, however, be but little doubt that a smokeless powder of some sort will, before long, be universally adopted by all the great powers of Europe, not only for rifles, but also for artillery purposes; it is no longer a question as to whether a smokeless powder should be adopted or not, but which of all the smokeless powders experimented on is the best for adoption. Smokeless powders, in order to be suitable for military purposes, must not be too violent in their action, they must be able to stand extremes of heat and cold, they must not be very hygroscopic, and they must keep well in store without deteriorating in quality; and the problem to solve is to find a powder which will fulfil these conditions. Nearly all smokeless powders consist essentially of gun-cotton, or other lower forms of nitro-cotton, acted on by a solvent such as acetic ether or acetone, which reduces the nitro-cellulose to a viscid paste; the paste is then rolled out into sheets, and the solvent allowed to evaporate; the sheets are left as a dense horny substance, and are cut first into strips, and then the strips are cut crosswise into grains of any required size; or the substance can be left in strips or in a fibrous form.

The French, in 1887, were the first to adopt a smokeless powder for the cartridges for their new small-bore rifle, the Lebel. It is known as Vieille's powder, or 'Poudre B;' its exact composition has been kept a secret, but it is believed that picric acid is mixed with the paste as described above. The ballistics attributed to this powder when first introduced were remarkable; a charge of about 70 grains imparted a muzzle velocity of 2000 feet per second, to a bullet weighing 230 grains, fired from a rifle-barrel whose calibre was ·315″. But it was found that the powder rapidly deteriorated, and that these results were only attainable with recently manufactured powder. Hence in 1889 the French adopted another powder, the French B.N. Powder, the exact composition of which is kept secret.

The English government, after very exhaustive trials with various kinds of smokeless powders, eventually adopted in 1891 the powder known as *cordite* for use in Her Majesty's land and naval forces. The name comes from its being made in the form of string or cord, the size of the cord being dependent on the size of the gun for which it is required. It is a nitro-glycerine powder, and consists of 58 per cent. of nitro-glycerine, 37 per cent. of gun-cotton, and 5 per cent. of mineral jelly, acetone being used as a solvent. These ingredients are thoroughly mixed or incorporated in a machine, in which are two revolving blades somewhat in the form of the screw of a steamer. This process, which takes seven hours, converts the mixture into the form of a thick paste, the paste being the same for all sizes of cordite. For rifle cordite, the paste is pressed through a small hole, ·0375″ in diameter, in a cylinder, and is wound off on to reels, each reel holding 1 lb. of cordite. The cordite is then dried in a drying-room at a temperature of about 105° Fahrenheit to drive off the acetone, and in this form is ready for use for loading into rifle cartridge cases. For larger guns, the cordite paste is pressed through plates having holes of various diameters—the larger the gun the larger the diameter of the cord. The sizes at present in use for quick-firing guns are as follows:

For 3 and 4 pr. 2 ms.	diameter ·05″	length of cord	11 inches.
,, 12 ,,	,, 1 ,,	,,	11 ,,
,, 47 ,,	,, 2 ,,	,,	14 ,,
,, 6 ,,	,, ·3 ,,	,,	14 ,,

For heavier natures, the diameter varies from ·4″ to ·5″, and length of cord is also greater. The weight of a charge of cordite varies from one-half to two-thirds of that of black powder, and with this charge a higher velocity is obtained with a lower pressure.

The German military powder is also a nitro-glycerine compound. It is very similar to Nobel's *ballistite*, in which the proportion of nitro-glycerine and gun-cotton are about equal, benzol being used as a solvent; and instead of being pressed into cords, it is rolled under rollers into sheets, and then broken up into grains of various sizes.

The Smokeless Powder Company have also made a powder suitable for military rifles, called *rifleite*; as also a very good sporting smokeless powder known as S.S. These powders are made of nitro-cellulose in the form of nitro-lignine, the various shooting qualities being obtained by the mixture of the higher and lower nitrates of lignine, nitro-benzol being used as a solvent.

The following powders are extensively used for sporting purposes—viz.: *Ballistite*, already mentioned; *Cannonite*, which is a nitro-cellulose powder, the gun-cotton being dissolved in ether, and formed into a plastic mass, in which form it is pressed through a cylinder with very small holes in the bottom plate, somewhat in the form of rifle-cordite. These thin strings when dried are then broken into grains by being passed through revolving rollers. *Amberite* is another nitro-cellulose powder, the gun-cotton being mixed with paraffin and shellac. *Walsrode* is a German powder, and is a pure gelatinised nitro-cellulose. The gun-cotton being completely dissolved in solvents, the plastic mass being divided into grains by rotation in a barrel.

This powder is known as a condensed powder, the charge necessary to produce the required velocity occupying a very small space. The *Normal powder* is very similar to Walsrode.

One of the most powerful explosives known is *blasting gelatine*, made by dissolving 7 per cent. of gun-cotton in 93 per cent. of nitro-glycerine; it forms a gelatinous mass somewhat resembling honey in colour, and varying in consistency from a tough leathery material to a soft substance like stiff jelly. It is stronger than dynamite, as the nitro-cellulose itself is explosive, and, if made with great care, and if absolutely free from all impurities, is a safe and stable explosive. But, unless the ingredients of which it is composed are absolutely pure and free from all foreign matter, it becomes exceedingly dangerous when stored in large quantities, and is liable to spontaneous combustion.

See Wardell, *Gunpowder and Gun-cotton* (1889); Cundill, *Dictionary of Explosives* (1895); Eissler, *Modern Explosives* (1889); Guttmann, *Manufacture of Explosives* (1895); Sanford, *Nitro-Explosives* (1896). See also CELLULOID, RIFLES.

Gundamuk. See GANDAMAK.

Gun-factories, ROYAL, form one branch of the Royal Arsenal at Woolwich, the other two being the Royal Laboratory and Royal Carriage Department; see WOOLWICH. The process now adopted in manufacturing guns is explained under CANNON. The Elswick foundry was for some time recognised as an auxiliary and supplement to Woolwich Arsenal, the guns being turned out at a contract price, payable after rigid inspection. The close connection between them ceased in 1863, but many orders are still executed for government by the Elswick firm.

Gungl, JOSEF (1810–89), composer, born at Zsambek in Hungary, entered a military band as oboist, and was its conductor for eight years. In 1843–48 he gave concerts in Berlin, and there in 1849, after a visit to America, he was appointed director of the royal concerts. From 1858 to 1864 he was bandmaster of an Austrian regiment; but most of his remaining years were employed in concert tours. Of his 400 compositions most were waltzes or other dances.

Gun-metal. See CANNON.

Gunnel (*Centronotus*), a genus of coast fishes in the Blenny family, but with more elongate eel-like form than the true blennies. The British species (*C. gunnellus*), the spotted gunnel or butterfish, is common on British coasts, lurking under stones in tidal pools. The colour is deep olive, with a dorsal row of black spots surrounded by white rings; the usual length is about 6 inches; the skin is thickly coated with a mucous secretion. It is seldom used except for bait.

Gunner, in the British army, is a private soldier of the Royal Artillery. His pay is 1s. 2½d. per diem, except in the Horse Artillery, where it is 1s. 4d.; his uniform is blue with red facings, red stripes on the trousers, and yellow worsted lace. His arms consist of a carbine and sword-bayonet in the garrison artillery, and a cavalry sword in the horse. In the field artillery gunners carry no arms, but two carbines are strapped on to each limber. *Master-gunners* are warrant officers of artillery, generally placed in charge of one or more forts; the first class receive 6s., the second, 5s. 8d., and the third, 4s. 6d. a day. The office has much degenerated in importance since it was first created, at least as early as the time of Henry VIII.

In the *navy* the gunner is an officer from the ranks qualified in gunnery, appointed by warrant from the Admiralty. Rank next after chief-gunner, below second-lieutenant in the army, but above master-gunner. Pay, from 5s. 6d. to 8s. 3d., with allowances in special cases. Pension, at age of fifty-five or when unfit, not exceeding £120 a year. Must pass examinations on board gunnery ships at Portsmouth or Plymouth. Uniform similar to undress of sub-lieutenants, but without distinguishing marks, and with black-hilted sword. Duties: takes charge of all the ordnance stores on board ship, and is responsible under superintendence for their expenditure and account; has a general oversight of everything relating to the weapons employed and their proper use, either under a gunnery officer or where there is none. Is entitled to a cabin. Gunners are now sometimes appointed in place of sub-lieutenants for quarter-deck duties and to command torpedo-boats, &c. *Chief-gunner* is a commissioned officer promoted by selection from the gunners. Rank next after sub-lieutenants in the navy and with second-lieutenants in the army. Pay, 9s. per day, and pension at fifty-five or when unfit, not exceeding £150 a year. Uniform the same as gunner, but with a single gold stripe and loop on each cuff, the same as sub-lieutenant. Duties the same as those of gunner. Both chief-gunner and gunner are eligible for promotion to the rank of lieutenant in special cases. *Gunner's-mate* is a first-class petty-officer, selected after examination on board the gunnery ships from men qualified as seamen-gunners. Wages the same as other first-class seamen petty-officers, from 2s. 2d. to 2s. 5d. per day, but with extra pay for gunnery qualifications varying from 2d. to 8d. per day. Uniform the same as other first-class seamen petty-officers, but with devices on right sleeve denoting gunnery qualifications. Duties, assistant to those of gunner. *Chief-gunner's mate* is a chief petty-officer promoted from the gunner's-mates. Pay, from 2s. 8d. to 3s. 2d. per day, with extra pay for gunnery qualifications. Uniform, that of other seamen chief petty-officers, but with gunnery devices on right sleeve. Duties the same as gunner's-mates. *Seaman-gunner* is a seaman qualified in gunnery subjects on board one of the gunnery ships, for which he receives from 2d. to 4d. per day extra pay.

In the United States navy, gunners' wages, like those of boatswains and carpenters, range from $700 when on leave or waiting orders during the first three years' service, to $1800, when at sea after twelve years' service.

Gunnery is the science which governs by its laws the construction and employment of all fire-arms, though the term 'musketry' is generally applied to the scientific use of small-arms. It involves a knowledge of the properties of metals, and details of their manipulation in gun-manufacture, as well as the calculation of the strains to which the weapon will be subjected, the velocities of projectiles, and the effect upon them of the various forces to which they are exposed in the bore of the gun and during their flight through the air.

This subject was first treated of by an Italian mathematician, Nicolas Tartaglia, who in 1537 published *La Nuova Scientia*. He also invented the gunner's *quadrant*. Many other writers followed him, of whom the principal was Galileo, whose *Dialogues on Motion* were printed in 1638. But the real founder of the science was Benjamin Robins (q.v.), whose *New Principles of Gunnery* appeared in 1742, and treated of atmospheric resistance, the force of gunpowder, the effects of varying the length and weight of guns, &c. His invention, the Ballistic Pendulum (q.v.), enabled the velocity of a cannon-ball to be measured, and was generally used for that purpose until superseded by Navez's electro-ballistic pendulum about 1862. Euler, Halton, and others added by their

commentaries on Robins's work to the general knowledge of the subject which existed up to the end of the 18th century. In 1840 Professor Wheatstone invented an electric chronoscope for measuring velocities, which was followed by those of Navez-Leurs, Bashforth, Noble, and De Boulengé. In 1878–80 the Rev. F. Bashforth produced his chronograph for measuring the resistance of the air to the motion of elongated projectiles. By means of his tables and the various instruments now placed at their disposal, mathematicians are able to calculate the proper length, thickness of metal, size of chamber, charge, form of projectile and method of rotating it for a gun of given calibre, and also to determine the time of flight, penetration, height and velocity at any point, and elevation required for any range, &c. The latter are most necessary in order that the gun may be skilfully handled, and each weapon has its 'range table' made out, giving these particulars.

The official *Text-book of Gunnery* (1887), by Major Mackinlay, R.A., is one of the best modern treatises on this subject, and has been largely quoted in foreign works, notably in the *External Ballistics* of Captain Ingalls, U.S. Artillery.

In 1880 Major F. Siacci, of the Italian Artillery, put forward a method of solving trajectories and problems in ballistics, and his formulæ have been used by artillerists of all nations with very satisfactory results.

Without explaining the intricate calculations and delicate instruments used, it may be interesting to give a few examples of gunnery problems. A shot was fired at Shoeburyness in 1887, and called the Jubilee shot, from a 9·2-inch wire-gun at an angle of 40° elevation, by which it was thought an extreme range would be obtained. The calculated range was 20,765·3 yards (say 12 miles); maximum height, 17,110·6 feet; time of flight, 63·787 seconds; angle of descent, 53° 50′. The actual range was 20,236 yards.

The necessary elevation for a 12-inch 45-ton gun, firing with a charge of 295 lb. and a muzzle velocity of 1910 feet per second at a point 3000 yards distant and 1270 feet above it, is found to be 2° 25′. An 8-inch howitzer of 70 cwt. is to breach the escarp of a ditch 50 feet wide, with common shell and delay-action fuze—the angle of descent must be 14° and the striking velocity not less than 600 feet per second; required the least necessary distance of the howitzer from the escarp, the requisite charge of powder, and angle of elevation. Answer, 1936 yards, 6 lb. R.L.G.^{2} powder, and 13° 23′.

In designing a rifle of which the velocity is to be 800 feet per second at 1000 yards, and trajectory in no place higher than 32 feet, it is necessary to know the proportions of weight of bullet to calibre, which are found by Siacci's formulæ to be 358 grains for a calibre of ·38 inch, or 254 grains for ·32-inch calibre.

From these and similar examples it will be understood that gunnery has become one of the exact sciences. The excellence of modern machinery enables the manufacture of weapon, projectile, powder, and fuze to satisfy the demands of the theorists, while such inventions as Watkin's position and range finders and Scott's telescopic sights put it in the power of the trained artilleryman to show equally good results in practice. See BREECH-LOADING, CANNON, RIFLE; for the School of Gunnery at Shoeburyness, see ARTILLERY.

Gunny-bags are made of a coarse jute fabric (see JUTE), and are very largely exported from India to various parts of the world. American cotton is largely packed in these. They can be manufactured at a low price, hence the great demand for them. The name gunny is applied to the cloth as well as to the made-up bags. About 1850 the peasant hand-looms of Lower Bengal met both the home and the foreign demand for Indian-made gunny bags indeed the making of these was then the great domestic industry of that portion of India, giving occupation to men, women, and children of nearly every class. Even boatmen and domestic servants employed their spare moments at them. At the present time the number made at the great steam-factories, of which there are now twenty-three in India, far exceeds what is produced by hand-looms. For example, in the year 1885, 82,779,207 gunny-bags were exported from India, of which only five millions were woven by hand. In the same year forty millions of these bags were sent from Bengal to other parts of India, and it was estimated that nearly as many were used in Bengal itself. The total value of the Bengal trade in jute manufactures (mainly gunny-bags or cloth) in 1885 was believed to be not far short of £3,000,000. In India gunny-bags are employed for agricultural and internal trade purposes, but many are also sent out of the country filled with grain and other produce. Cloth and bags of the same kind are made in Dundee.

Gunpowder is a well-known explosive mixture composed of saltpetre, charcoal, and sulphur mixed together in certain proportions, somewhat varying in different countries and in different descriptions of powder.

The early history of gunpowder is very obscure; but there appears to be little doubt that the explosive nature of saltpetre (the great bulk of which comes either from India or China) when mixed with charcoal or carbon was known to the Chinese for many centuries before the Christian era. It may be assumed that the discovery of this property of saltpetre was accidental: a wood-fire lighted on the earth where saltpetre was mixed with the soil would bring the two ingredients together, and the action of the heat would be sufficient to show the nature or property of the mixture so brought about when raised to a certain temperature. It is certain that fireworks were known in China from very early periods; but in a pamphlet written by Colonel Omodei (Turin, 1834), and later in an article in the *Athenæum* of December 26, 1868, by Captain (now Lieut.-General) Henry Brackenbury, R.A., the question as to the first invention of gunpowder was fully discussed, and the conclusion arrived at was that there is great reason to doubt whether either the Chinese or any other Asiatic people invented gunpowder in its true sense, or were the first to use it as a propelling agent. It was left for more western nations to develop the discovery of the Chinese, and our first knowledge of the use of gunpowder as a military agent dates from the 7th century, when it was used by the Byzantine emperors, under the name of Greek Fire (q.v.), in the defence of Constantinople against the Saracens, who, discovering the secret of its manufacture, used it against the Crusaders, not however as a propelling agent, but in the form of rockets or liquid fire. Its first use in Europe as a propelling agent was in Spain, where both the Moors and Christians used some description of artillery as early as the 12th century. Roger Bacon first introduced it into England. Whether he discovered it independently of foreign aid, or whether he conceived the idea from ancient manuscripts, is uncertain; but the latter is the more probable, as the name first given to it was *crake*, presumably a corruption of the word *grec*. Bacon's discovery dates from a period early in the 13th century, but, owing to the crude and uncertain means adopted for mixing the ingredients, it was of no practical value till the German monk, Berthold Schwarz, introduced, somewhere about the year 1320, a method of manufacture by which the ingredients were thoroughly

incorporated; the meal powder thus made was first used in England as a propelling agent by Edward III. in his war against the Scotch in 1327, the tubes from which he propelled the shot being called *crakeys of war*. The same king subsequently used cannon at the battle of Crécy in 1346. From that date the use of gunpowder throughout Europe soon became general, the Russians, who in 1889 celebrated the 500th anniversary of its introduction into Russia, being the last to adopt it. Until the reign of Queen Elizabeth by far the larger quantity of powder required by the English was obtained from abroad; but in her reign its manufacture was introduced into England. The earliest English powder-mills of which there is any record were established at Long Ditton and Godstone, in Surrey, by George Evelyn (John Evelyn's grandfather) in 1590; the Faversham mills were started soon after this date, as were also those at Waltham Abbey. The mills at Faversham subsequently became the government powder-factory, and in 1787 the government also bought the mills at Waltham Abbey, which have remained in its hands down to this day. The Faversham mills were given up by the government after the peace of 1815; they were soon after bought by Messrs John Hall & Son, who still retain them.

The mode of manufacture adopted in England when these several powder-mills were all thoroughly established remained practically unchanged up to within the last thirty-five years. But before proceeding with a description of the manufacture and of the different powders now in use, it will be desirable to consider very briefly the part played by the several ingredients of which gunpowder is composed, and the chemical action which takes place on ignition. The saltpetre or nitrate of potash, KNO_3, acts as a magazine of oxygen, with which it readily parts when raised to a certain temperature. When the powder is fired, the oxygen of the saltpetre converts most of the carbon of the charcoal into carbonic acid, CO_2, a portion of which combines with the potash of the nitre to form carbonate of potash, KCO_3, the remainder existing in the state of gas, and the nitrogen is liberated. The sulphur, which performs the part of a second combustible in gunpowder, is for the most part converted into sulphuric acid, SO_3, and forms sulphate of potash. The reaction on firing the gunpowder may be expressed by the equation $KO,NO_5 + S + 3C = 3CO_2 + N + KS$. The heat generated by the explosion evolves a large quantity of elastic gases, the expansive power of which is greatly increased by the heat. The pressure being equal in all directions, the work done on the projectile in the bore of the gun is due to this elasticity and expansive force. The method adopted for measuring the amount of pressure in the bore of the gun will be dealt with hereafter.

Sir Frederick Abel, K.C.B., F.R.S., and Sir Andrew Noble, K.C.B., carried out two series of most exhaustive and complete experiments on fired gunpowder, and the conclusions they arrived at were communicated by them to the Royal Society in two papers (1875–80) under the head of 'Researches on fired Gunpowder.' The results are summarised as follows: when fired in a confined space (1) the products of combustion are about 57 per cent. by weight of ultimately solid matter and 43 per cent. of permanent gases; (2) the permanent gases occupy about 280 times the volume of the original powder; (3) the tension of the products of combustion when the powder entirely fills the space in which it is fired is about 6400 atmospheres, or 42 tons per square inch; (4) the temperature of explosion is about 4000° F.; (5) the chief gaseous products are carbonic acid, nitrogen, and carbonic oxide; (6) the solid residue is mainly composed of potassium carbonate, sulphide, and sulphate.

From the foregoing description of the part played by the nitrate of potash it might be thought that it would be highly advantageous to make gunpowder with some nitrate containing a larger percentage of oxygen than nitrate of potassium; and as a matter of fact there are a large number of nitrate mixtures other than gunpowder in which nitrate of sodium, barium, or ammonium are substituted for the nitrate of potassium. But unfortunately they are extremely hygroscopic, so that gunpowder made with them would, under ordinary circumstances, soon become useless on account of the damp it would absorb from the atmosphere. In a hot dry climate nitrate of soda powders would doubtless be valuable, besides being much cheaper to manufacture than nitrate of potash powders: indeed such powders were used to a considerable extent in the construction of the Suez Canal; but, as these powders are not in general use, it is unnecessary to refer to them further.

Process of Manufacture.—The method of manufacture of gunpowder at the Royal Gunpowder Factory at Waltham Abbey (fully explained in the official handbook) may be briefly described. As in all other explosives, it is essential that the ingredients of which the powder is composed should be as pure as possible. The selection and preparation of the charcoal is of the greatest importance; for, without any change in the proportions of the components, the properties of the gunpowder are capable of great variation from the quality of the charcoal used in its manufacture. The ingredients are first reduced to a fine powder by grinding. They are then mixed by hand in the proportion of 75 per cent. by weight of saltpetre, 15 of charcoal, and 10 of sulphur, and are next thoroughly incorporated in a wet state in a powder-mill into a cake called a mill-cake. This cake is then broken down between copper-plates into meal. From this meal-powder all granulated powders are made. The meal is compressed in a press-box, the amount of compression it undergoes being dependent on the density of powder required. After compression the press-cake is broken into pieces ready for granulating, which is done in the granulating machine, the powder passing between gun-metal rollers till it is broken into grains of the required size, different powders being made to pass through sieves whose meshes are of the size of the grain required. There is a considerable amount of dust formed by the granulating process, so that after granulating it is necessary to dust the powder previous to glazing it, which is the next operation. It is glazed in glazing drums, which, revolving rapidly, impart a glaze to the powder simply by the friction set up. The powder is now stoved or dried in copper-trays in a drying room, which is heated to a temperature of about 100° F., and the powder is left in this room from one to two hours according to the amount of moisture that it contains. Formerly all powder was granulated, but the enormous increase in the size of the guns now used necessitated the introduction of other descriptions of powder viz. *cut* and *moulded* powders. In the cut powders, after the process of *pressing*, the press cake, instead of being granulated, is first cut into strips, and these strips are then cut into cubes, and the powder so made is called cubical or pebble powder; there are at present two sizes—viz. ⅝-inch and 1½-inch cubes. In the moulded powders, as is implied in the name, each grain or piece of powder is moulded or pressed in a separate mould. This is done in a hydraulic machine. The exact quantity of granulated powder required to form each prism is deposited in a block containing sixty-four moulds; the powder in these

moulds is then pressed by plungers exactly fitting the moulds till the required density is obtained. This powder is called *prismatic powder*, the grains or pellets being in the form of hexagonal prisms nearly 1 inch in height and about 1⅛ inch across, with a hole in the middle about $\frac{1}{10}$th of an inch in diameter, the object of which will be explained later on. There are two descriptions of prismatic powder—black and brown. The proportions of ingredients in the black powder are the same as in all other English military powders; but in the brown powder the charcoal is made from straw, instead of from wood, and the proportion of the ingredients are as follows: viz. saltpetre 79, charcoal 18, and sulphur 3 per cent.

Gunpowder more nearly fulfils the objects required in a propelling agent than any other explosive hitherto discovered. These objects are (1) a maximum muzzle velocity with even and low pressures; (2) uniformity of action, so that the same results may always be expected; (3) freedom from fouling; (4) durability—i.e. that it is not liable to injury in transport, and that its condition does not materially alter when stored.

The advantages of gunpowder over other explosives are (1) that, the rate of combustion being gradual, the explosion is not so severe on the bore of the gun as in the case of more violent explosives; (2) the ingredients of which it is composed are easily produced and are cheap; (3) it is, with proper precautions, safe in manufacture, in store, or in transport. Experiments made by the Explosives Committee have shown that any alteration in the proportions of the ingredients has not so great an influence on the 'explosiveness' or rate of burning as the density, hardness, size, and shape of grain and amount of glaze. The density of grain has an important effect on the rate of burning. By absolute density is meant the amount of powder actually present in a certain bulk—i.e. if different quantities of meal-powder, containing an equal amount of moisture, be pressed into cakes of the same size, that which contains the most meal will be densest; then, if these cakes be ignited simultaneously, the cake which has the least density will be the first to be completely burnt. Hardness does not depend on density; increased hardness is given by pressing the meal in a moister condition. Size and shape of grain are also important characteristics to be considered in connection with the explosiveness of powder. Other things being equal, a larger-grained powder burns slower than a smaller-grained; and in grain of equal weight that which has the largest surface will burn the quickest. A highly-glazed powder, again, burns slower than an unglazed one, probably because the glaze somewhat retards its thorough ignition. The temperature at which powder ignites varies from 530° to 600° F., according to the nature of the powder, the finest sporting powder igniting at the higher temperature.

It is only of late years that all these points have received the attention they deserve, but they have been forced upon the authorities by the necessities of the times. As soon as ships began to be plated with armour, guns had to be made which could throw a projectile capable of piercing that armour; and as the armour increased in thickness so did the guns increase in size and power, throwing heavier projectiles, which necessitates an enormous powder charge to propel the shot. In former days there was a beautiful simplicity about powder. Practically there were but two kinds, one for muskets called fine grain or F.G., and the other for cannon called large grain or L.G., and no particular attention was paid to the quality; it was certainly not subjected to the searching proofs and tests which all powders made in these days have to undergo. The first improvement in powder took place on the introduction of rifled arms, when a rifle fine-grain powder or R.F.G., slightly larger in the grain than F.G., and a rifle large-grain powder or R.L.G., the grains of which were about twice the size of those of L.G., were introduced for small-arms and cannon respectively. The R.F.G. powder was improved and made of a rather smaller grain, the size of grain being from $\frac{1}{12}$th to $\frac{1}{20}$th of an inch, on the introduction of the Martini-Henry rifle, and this powder, known as R.F.G.^{2}, has not since been altered. But in cannon powder, or powder for large guns, the development has been great and continuous. When R.L.G. powder was introduced it was the largest grained and slowest burning powder then in existence in England; but as the guns were made larger and larger it became necessary to use a slower-burning powder, which led first to the introduction of R.L.G.^{2}, having grains varying in size from 3 to 6 to the inch; that is, the grains must pass through a sieve of 3 meshes to the inch, and must not pass through one of 6 meshes to the inch. A short time afterwards a still larger powder called R.L.G.^{4}, with grains of nearly half an inch in size, was introduced. This was soon followed by pebble powder, a still further development of R.L.G., for guns of large calibre for which R.L.G.^{4} was not suitable. The first pattern of pebble or P. powder was cut in cubes of about half an inch in size, and a second pattern or P.^{2} was made in cubes of about 1½ inch in size, with rounded edges. Both these powders have a density of 1·75, whereas that of the R.L.G. powders is 1·65. Next in order came the prismatic powders, of which there are two descriptions—viz. prismatic black or Prism^1 and prismatic brown or Prism^1 brown, a description of which has been given under the head of manufacture. There are two other powders of a special pattern which may be mentioned—viz. M.G.^{1} which is used only in the 1-inch Nordenfelt machine gun, the size of grain of which is considerably larger and of more even size than that of R.F.G.^{2}; and Q.F.^{1}, a powder which at present is used only in the 3- and 6-pounder quick-firing guns, the size of grains being about half an inch square by about $\frac{1}{10}$ of an inch thick.

The powders of other nations differ but slightly from those manufactured in England; the method of manufacture is the same in principle, but the proportions of the ingredients vary to a slight degree in every nation.

Having now described the various powders in use, it remains to say a few words about velocities and pressures. The great desideratum with all firearms is to obtain the maximum velocity with the minimum of pressure, and in the experiments and investigations carried out by the committee on explosives, and by Sir F. Abel and Sir A. Noble, this end was kept in view. It has already been pointed out that the rate at which powder burns depends greatly on the density, hardness, size, and shape of grain: the greater the density the slower it will burn; the larger the grain the slower it will burn, simply because the amount of lighting surface is reduced in proportion to the volume; and the smoother the surface of the grain the slower it will burn for the same reason. A powder therefore composed of, comparatively speaking, small grains of irregular size and shape, burns very rapidly, and generates a large volume of gas suddenly, thus setting up a very high pressure in the bore of the gun. In some of the experiments of the committee the pressure recorded in the bore of the gun was as high as 60 tons to the square inch; but, as Captain Noble had previously discovered that the maximum pressure of powder fired in a confined space did not exceed 42 tons, this extra pressure could only be due to wave-action, a sudden

evolution of gas locally causing a vibratory motion of the gas. This led to the introduction of larger-grained powders, so as to retard the burning of the charge, but this did not entirely do away with the wave pressure. It was next sought to diminish the pressure by giving air-space to the charge, as it was found that the density of the charge—not the density of the grain—materially affected the pressure; this air-space was given by enlarging the chamber of the gun, and although it became necessary to increase the charge so as to maintain the same muzzle velocity, it was found that the pressure was sensibly diminished.

But whilst Great Britain was still adhering to pebble powder, other nations had adopted a prismatic powder with a hole through the centre of the pellets or prisms. The idea of this perforated powder is due to General Rodman, an American artillery officer, who thought that by this means a charge of powder would evolve the gas at a more uniform rate. In a charge composed of solid grains, the grains being lighted on the surface and burning towards the centre, the surface giving off gas rapidly decreases, and therefore the volume of gas given off by the grain will be greatest when the charge is first fired, and will rapidly fall off; hence the maximum pressure on the bore of the gun is set up almost before the projectile commences to move. To overcome this, the idea occurred to General Rodman to have a hole through each large grain or pellet of powder, so as to give the grain an interior as well as an exterior lighting surface, so that as the exterior lighting surface *decreased* the interior lighting surface *increased*, thus preserving the ignited surface more uniform during the burning of the pellet, and therefore keeping up a more constant evolution of gas. This tends to distribute the pressure more uniformly along the bore of the gun, and increases the initial velocity of the projectile. The Russians in 1860 were the first to adopt this plan, followed by the Germans, the English being the last to take it up; it is now, however, adopted for the heaviest guns in the English service, the charge being built up of the hexagonal prisms already described, so arranged that the holes through each column of prisms shall be continuous from one end of the charge to the other. The introduction of this powder has enabled the type of gun to be entirely altered; a description of the guns now in the service will be found under the head of Cannon, Rifles (q.v.). We are indebted to the Germans for the invention of brown or cocoa powder; it is claimed for this powder that it gives a higher initial velocity with less pressure than the same charge of black powder.

The same principles as have been enunciated here with regard to guns should govern the selection of powder for mining or blasting purposes. If it is desired to shatter a mass of rock, a very violent quick-burning powder, having a great disruptive force, should be used; but if it is only desired to dislodge, say, a mass of coal without shattering it, a denser, slower-burning powder should be chosen.

The instrument generally used for taking velocities is a chronograph, the invention of Major De Boulengé of the Belgian Artillery. It consists of a brass column supporting two electro-magnets. No. 1 electro-magnet supports a long cylindrical rod, called the chronometer, covered by a zinc tube; No. 2 electro-magnet supports a shorter rod. Two screens of copper wire are placed at certain fixed distances in front of the muzzle of the gun. No. 1 electro-magnet is magnetised by the current passing through the first screen, and No. 2 by the current passing through the second screen. As the shot passes through the first screen the current is broken, and the rod or chronometer suspended by No. 1 electro-magnet falls by gravity. Similarly, when the shot passes through the second screen, the shorter weight suspended by No. 2 electro-magnet falls on to a disc, which, pressing a spring, causes a knife to be released, and this, darting forward, strikes the chronometer in its fall, making an indent in the zinc tube. The distance of this indent from the zero point being measured off on a scale specially graduated for the instrument gives the velocity of the shot between the two screens, from which can be calculated the muzzle velocity. Another scale gives the time of flight.

The pressures in the bore of the gun are calculated by means of a crusher gauge. A small copper cylinder is inserted in the gauge, which is screwed into the gun at that part where it may be desired to measure the pressure. The copper cylinder is measured before and after the discharge of the gun, the amount by which it is shortened by the force of the explosion being the measure of the force, or pressure, exerted. The actual pressure in tons to the square inch is calculated by means of a mathematical table prepared for different coppers.

See Wardell, *Gunpowder and Gun-cotton* (1889); Cundill, *Dictionary of Explosives* (1895); Eissler, *Modern Explosives* (1889); Guttmann, *Manufacture of Explosives* (1895); Sanford, *Nitro-Explosives* (1896). For Smokeless Gunpowder, see Gun-cotton, Rifles; and for laws relating to gunpowder, see Explosives.

Gunpowder Plot. This plot was an attempt on the part of a small number of Roman Catholic gentlemen to destroy by gunpowder King James I. and the Houses of Lords and Commons on the day of the opening of parliament, November 5, 1605. The design originated in the busy brain of Robert Catesby (q.v.), who had already suffered for the part taken by him in Essex's plot. He and his fellow-conspirators were driven to desperation by the faithlessness of James, who before his accession had led the Catholics to expect some measure of toleration, but soon afterwards put in full force the penal laws against popery, and showed a disposition to increase rather than to mitigate their rigour. Early in 1604 Catesby communicated his plan to John Wright and Thomas Winter. Guy Fawkes (q.v.), a brave soldier serving in the Spanish army, was brought over from Flanders, and together with Percy was admitted to the plot after taking an oath of secrecy. All five then received communion from the hands of the Jesuit Gerard, who, however, was not informed of the conspiracy. On 24th May Percy hired a room adjoining the Parliament House which they intended to undermine. The adjournment of parliament from time to time caused sundry postponements of the work. In December the digging was begun. The difficulties were greater than was expected, and it became expedient to call in the assistance of fresh associates—John Grant, Robert Winter (brother of Thomas), and Bates, a servant of Catesby. In the following March the conspirators were able to hire a convenient cellar immediately below the House of Lords. The mine was now abandoned, and the cellar was stored with casks of powder, covered with faggots.

All was ready by May. Money was now wanted to provide men, horses, and arms for the insurrection, which it was intended should break out in the midland counties, where the chief conspirators had congregated. So about Michaelmas some rich Catholics, Sir Everard Digby, Ambrose Rookwood, and Francis Tresham were induced to join. Tresham lacked the courage and fanaticism of his fellows. Wishing to save his friend Lord Monteagle, he wrote to him on Saturday, October 26, a mysterious letter, which was shown to Lord Salis-

bury and led to the discovery of the plot, if it had not otherwise been already betrayed. The names of the conspirators were, however, not disclosed. The government, therefore, waited for the fuller development of the plot. The cellar was visited as if casually by the Lord Chamberlain and Lord Monteagle at three o'clock on the afternoon of the 4th. Fawkes, who was found there, explained that the fuel and faggots were the property of his master, Percy. He still hoped to carry his design into execution, and a little before midnight he returned to the cellar to take up his post for the night. He was met and arrested at the doorway. Catesby hastened to Warwickshire, hoping to raise his friends. A few days later they were attacked; several of the conspirators, including Catesby, were killed, and others were taken prisoners and committed for trial. From their confessions the whole plot was gradually revealed.

The government was now much concerned with a suspicion that the murderous design had been promoted or approved by the Jesuits. Bates had in his confession implicated certain fathers of the society, especially Garnet (q.v.) and Greenway. The latter made good his escape abroad. Garnet and a brother Jesuit, Oldcorne, who was convicted of nothing more than aiding in the concealment of his companion, were discovered in a priest's hiding-place at Hindlip, whither Garnet had fled from Coughton, in the neighbourhood of the appointed rendezvous of the conspirators. Their trial excited the greatest interest. It soon became evident that Garnet's knowledge, such as it was, of the plot had been forced upon him by the conspirators, who were anxious to obtain from him some token of his approval for the satisfaction of their own doubtful consciences. He admitted that he had derived a general knowledge of some treasonable design against the government, in the first instance from Catesby, and that subsequently he had learnt the particulars from Father Greenway in confession. On further examination Garnet expressed some doubt whether the communication made by Greenway was strictly sacramental or under the seal of confession, or at least whether Greenway himself so considered it. It was, moreover, elicited from Garnet that he had frequent conversations with Greenway on the plot, though always 'in relation to confession.' Finally, when Catesby wished to give him full information out of confession—information which would have released Garnet from all shadow of scruple in taking measures to reveal or prevent the crime—the Jesuit refused to listen to him. Some of Garnet's actions, both before and after the 5th November, gave probability to the belief that he knew more than he admitted, and was not unwilling that the plot should succeed. He blamed himself, indeed, for not having done more to prevent the mischief, and declared that he should suffer, not as a martyr, but as a penitent thief. It is, however, clear that the clergy in general, whether secular or regular, and the entire Catholic community, with the exception of a score of fanatics, were innocent of all participation in the plot.

See the *Narrative of the Gunpowder Plot* by David Jardine (1857), which treats the facts in a masterly and impartial spirit; Gardiner's *History of England*, vol. i. chap. vi.; and Tierney's edition of Dodd's *Church History*, vol. ii. In 1896 Father Gerard, S.J., tried in *What was the Gunpowder Plot?* to show that the evidence of a real plot was slight, and that the plot was itself partly manufactured by government agents; in 1897 Gardiner traversed this theory in *What the Gunpowder Plot was*.

Güns (Magyar *Kőszeg*), a free town of Hungary, 57 miles SSE. of Vienna, with a castle of Prince Esterházy. Pop. 7070.

Gunter, Edmund, mathematician, was born in Hertfordshire in 1581, and educated at Westminster and Christ Church, Oxford. Although he took orders and became a preacher in 1614, his mind was strongly bent towards mathematical studies, and in 1619 he obtained the professorship of Astronomy in Gresham College, London, a post which he held down to his death, 10th December 1626. His principal works are the *Canon Triangulorum* (Lond. 1620), a table of logarithmic sines and tangents to seven places of decimals, being the first table published in accordance with Briggs's system, and treatises on the *Sector, Cross-staff, and other Instruments* (1624). Gunter was the first to use the terms cosine, cotangent, and cosecant for the sine, tangent, and secant of the complement of an arc. To him are also due the invention of the surveying-chain (see Chain), a quadrant, and a scale, and the first observation of the variation of the compass.

The name of *Gunter's Scale*, or *Gunter's Lines*, is usually given to three lines to be seen on almost any sector, and marked N, S, T, meaning the lines of logarithmic *numbers*, of logarithmic *sines*, and of logarithmic *tangents*. To understand their construction and use requires a knowledge of logarithms; they are explained in every school-book of practical mathematics. The distances of the divisions marked 1, 2, 3, &c. on the line of log. numbers, represent the logarithms of those numbers—viz. 0, ·301, ·477, &c.—taken from a scale of equal parts. The other lines are constructed on an analogous plan. Calling to mind that multiplication of numbers is effected by the addition of the logarithms, division by their subtraction, involution by their multiplication, and evolution by their division, we are able to perceive with what ease many *rough* problems in areas, heights, cubic contents, and other matters may be performed through the agency of Gunter's Scale.

Guntur', a town in the presidency of Madras, 46 miles WNW. of Masulipatam, with an active trade in grain and cotton. Formerly badly built and overcrowded, it has been recently much improved. Pop. 19,646.

Gurgaon, a district of the Punjab, in the division of Delhi, with an area of 1984 sq. m. Pop. (1891) 668,929, over two-thirds Hindus. Agriculture is the chief employment; the soil is on the whole not unfertile, but there is little artificial irrigation, and the district has suffered greatly from drought. The commercial centre is Rewari (q.v.); the civil headquarters is Gurgaon (pop. 4000), 21 miles SW. of Delhi by rail, with some trade in grain.

Gurhwal. See Garhwal.

Gurjun Balsam, or Wood-oil, a balsamic liquid obtained from one of the Dipteraceæ (q.v.), which grows plentifully in the Andaman Islands. It resembles in characters and medicinal properties Copaiba Balsam (q.v.), and has at various times been sold as such. It has been used as a substitute for copaiba, chiefly in the Indian hospitals, but its chief use in the East is as a varnish for boats, and for preventing the attacks of ants on timber. At the request of Mr Manley Hopkins, the Hawaiian consul, the English government procured from the government of India in 1888 a large quantity of gurjun-oil, for checking or alleviating leprosy in Hawaii. It was used for this purpose by the late Father Damien (q.v.) amongst the lepers of Molokai.

Gurnall, William, theological writer, was born in 1616 at Lynn, in Norfolk, was educated at Emmanuel College, Cambridge, and in 1644 became rector of Lavenham in Suffolk, where he died, 12th October 1679. He is known as author of the devout, quaint, and pithy sermons on Ephesians, chap. vi., entitled *The Christian in Compleat*

Armour: a Treatise of the Saints' War against the Devil (1655–62; see the ed. of 1865, with biography by Ryle).

Gurnard (*Trigla*), a genus of acanthopterous fishes of the family Cottidæ, represented in tropical and temperate seas by about forty species, of which seven occur on British coasts. The head of the gurnard is angular, the eyes near the summit, the upper surface and the sides entirely bony, the teeth small and very numerous. The body is rounded, tapering, and covered with small scales; the air-bladder is often in two lateral parts provided with lateral muscles, and the broad pectoral fins are usually brightly coloured on the inner surface. The most marked peculiarity of the genus is the presence, in front of the pectorals, of three free finger-like rays. These are well supplied with nerves, and are organs at once of locomotion and of touch. Most of the gurnards live near the bottom, and feed on crustaceans, molluscs, and small fishes. When handled they emit a peculiar sound caused by the escape of air from the air-bladder—a fact which has gained for one species (*T. lyra*) the local name of 'Piper.' The most common British species is the Gray Gurnard (*T. gurnardus*). Its colour is brownish-gray, marked with white, and the lateral line bears a series of white, crested, bony plates. The Red Gurnard (*T. pini*) is also common, and is much used as food. It attains a length of about

The Sapphirine Gurnard (*Trigla hirundo*).

15 inches. Much rarer is the Sapphirine Gurnard (*T. hirundo*), so named from the beautiful blue of its pectoral fins. It grows to a length of about 2 feet. Gurnards are caught by the trawling-net or by hook and line.

Gurney, Joseph John, a philanthropic Quaker, born at Earlham Hall, near Norwich, August 2, 1788, was educated privately at Oxford, and in 1818 became a minister of the Society of Friends. His life was devoted to benevolent enterprises, including the prison reforms of his sister, Mrs Fry. He died January 4, 1847. Among his works are *Prison Discipline* (1819), *Religious Peculiarities of the Society of Friends* (1824), and *A Winter in the West Indies* (1840). See Hare, *The Gurneys of Earlham* (1895).

Gustavus Adolphus (Gustavus II.), king of Sweden from 1611 to 1632, was born at Stockholm, December 9, 1594, the son of Charles IX., and grandson of the great Gustavus Vasa. He was carefully educated, and grew up one of the most accomplished princes of his age. He knew eight languages, speaking and writing five of these with fluency, was well read in the classics and ancient history, proficient in music, and skilful in all manly exercises. When he came to the throne in his eighteenth year he found the country involved in wars abroad and disorders at home, arising from the disputed succession of his father, who had been elected king to the exclusion of the direct heir, his nephew, the Roman Catholic Sigismund, king of Poland. The first act of Gustavus was to secure the hearty cooperation of the nobles, by confirming their privileges subject to the performance of military service to the crown. Having reorganised the internal government, and raised both men and money, he made war on Denmark, and soon recovered his Baltic provinces, and a direct outlet towards Russia. His war with Russia was ended in 1617, by the treaty of Stolbova, by which Sweden obtained supreme dominion over Ingermanland and Karelia, and part of Livonia, while Russia recovered Novgorod and all other conquests made by the Swedes. In 1618 Gustavus visited Berlin in secret and fell in love with the strong-minded daughter of the Elector of Brandenburg, whom two years later he married. On that second visit in 1620 he traversed Germany as far south as Heidelberg. He next turned more actively to the intermittent dispute with Poland, which was at length terminated in 1629 by a six years' truce, which secured reciprocity of trade and freedom of religion to the natives of both countries, and left Gustavus master of Elbing, Braunsberg, Pillau, and Memel.

This peace enabled the king to mature the plans he had long cherished in regard to Germany, and accordingly, after making various administrative reforms at home, he remitted the charge of the government and the care of his infant daughter Christina to his chancellor Oxenstiern, and crossed to Pomerania about the midsummer of 1630, with but 15,000 men, to head the Protestants of Germany in their hard struggle against the Catholic League, which was backed by all the power of the empire and the resistless arms of Tilly and Wallenstein.

Everything favoured the success of the Swedes, who drove the imperialists from Pomerania, and took Stettin. The Duke of Pomerania, the aged Boguslav, last of the old Wendish line, engaged, in return for Swedish aid, that the dukedom should, after his death, be given up to Sweden until the expenses of the war were fully repaid; whilst Richelieu promised Gustavus a substantial subsidy as long as he maintained an army of 36,000 men. The Emperor Ferdinand had been obliged by the Electors to dismiss the imperious Wallenstein from his service. But, while the Swedes were besieging Spandau and Küstrin, the rich city of Magdeburg, which had applied for help to Gustavus, who could not move without the support of the hesitating Electors of Brandenburg and Saxony, was taken by Tilly. His troops perpetrated the most terrible atrocities upon the citizens, and all the buildings were burned to the ground save the cathedral alone. The Protestant German princes had been slow in coming in to Gustavus; but after John George of Saxony was driven into his arms by the impolitic demands of Ferdinand, Gustavus came more and more to be identified as the champion of their religion against oppression. Meanwhile the unselfishness of his own aims and his elevation of character, as well as the admirable discipline and the conduct of his hardy veterans in such strong contrast to the ungoverned license of the imperial troops, gained the confidence and admiration of all Germany. Soon after the fall of Magdeburg, Gustavus inflicted a severe defeat on Tilly at Breitenfeld, which taught the Catholics to fear the 'snow-king and his body-

guard,' as they designated Gustavus and his small army. The king now advanced into Franconia, and, after allowing his army to recruit their strength in the rich bishoprics of Wurzburg and Bamberg, took the Palatinate and Mainz, where he held a splendid court, surrounded by numerous princes and ambassadors. In the April of 1632 the Swedes, in the face of Tilly's army, crossed the Lech and gained a decisive victory, whence Tilly was carried to Ingolstadt to die. From thence the march to Munich was one continued triumph, and wherever Gustavus appeared he was received by the populace as their guardian angel. The road to Vienna was now open to him, and the fate of the emperor would have been sealed had the latter not recalled his haughty general, Wallenstein, who, having accepted office on his own terms, gathered together a large and heterogeneous army of 60,000 men, and advanced on Nuremberg, where he entrenched himself strongly. After withstanding a desperate assault of the Swedes he was obliged to retire into Thuringia. The unfavourable season, the bad roads, and the cautious dispositions of Wallenstein hindered Gustavus from attacking the imperialists as soon as he intended, but on November 6, 1632, the two armies came finally face to face at Lützen, ten miles to the south-west of Leipzig. A thick fog lay close upon the ground. The Swedes gathered to morning prayer to the music of Luther's noble hymn, 'Eine feste Burg ist unser Gott.' About eleven the mist cleared off, and Gustavus gave his last orders to his generals. Waving his sword above his head he cried 'Forwards,' and rode to meet the enemy at the head of the cavalry on the right wing. His eager troops soon broke the imperial lines, but Wallenstein bringing up his reserves drove back the Swedish infantry in the centre. Gustavus hastened too eagerly to the rescue, and, in the thick fog which had again descended, was separated from the cavalry he had ordered to follow him, and rode almost alone into a squadron of Croats. A shot passed through his horse's neck, another shattered his left arm, a third struck him in the back, and he fell heavily to the ground. A cuirassier riding up asked who was there. 'I was the king of Sweden,' murmured the dying king, whereupon the soldier shot him through the head. Bernhard of Weimar took up the command, while on the enemy's side Pappenheim's cavalry came up to take their part in the battle. The Swedes burned to revenge their king and fought with a fury that was irresistible. Hour after hour the battle swayed uncertainly, till at length, when Pappenheim had fallen and his artillery had been taken, Wallenstein drew his men off the field and left their hard-won victory to the Swedes. The body of Gustavus was recovered and laid to rest in the Riddarholm church at Stockholm.

So fell the great hero of the Thirty Years' War, and with him perished all hope of a speedy ending to the fatal struggle, and the establishment of a durable peace in Germany. His *Corpus Evangelicorum* was a noble imagination, and would have built up a Protestant power around the shores of the Baltic so strong as to defy all attack. But it is more than probable that a foreigner even so disinterested as himself might have failed to overcome the instinctive cohesiveness of even a divided Germany, and if so, he was happy in the accident of death on the field of victory, leaving behind him a deathless glory undimmed by failure.

See books on Gustavus Adolphus by J. L. Stevens (1885), Trench (new ed. 1886), C. R. L. Fletcher (1890), Colonel R. A. Dodge (New York, 1896), and other works cited at THIRTY YEARS' WAR.

Gustavus Vasa (Gustavus I.), king of Sweden from 1523 to 1560, was born in 1496, of a noble house closely allied to the Sture family, his own family name being Ericson. Still a boy, he became involved in the patriotic struggle with Christian of Denmark, and was treacherously carried off to Denmark, there to be kept in confinement with other nobles as hostages. After a year he escaped in disguise to Lübeck, thence to Sweden, where he went about from place to place striving, with great danger to himself, and with but little success, to rouse up a spirit of resistance against the Danes. At length he had to retreat to Dalecarlia, where he wandered for several months, in poverty and disguise, with a price set on his head, working with his hands on the farms and in the mines. At last the infamous 'Blood-bath' of Stockholm (1520) roused the slumbering fury of the Swedes, and gave Gustavus the opportunity he longed for. The hardy miners of Dalecarlia mustered round him, and ere long he had an army large enough to attack the enemy. One by one the strong places fell into his hands, and the capture of Stockholm in 1523 finally drove the Danes from the soil of Sweden. Thus fell the great Scandinavian union which had survived the treaty of Calmar (1397) for 126 years. At the diet of Strengnäs that same year Gustavus was elected king. Thenceforward he strove with unceasing zeal to heal the wounds of his unhappy country. He found the peasantry restless and disaffected, the Romish clergy wealthy, corrupt, and unpatriotic, the Lutheran party too eager to push their dogmas by force, and the whole country demoralised without respect to law or religion. Yet after forty years' rule he left Sweden a peaceful and civilised realm, with a full exchequer, and with a well organised army of 15,000 men and a good fleet—both his own creations. He promoted trade at home and abroad, fostered schools and colleges, made commercial treaties with foreign nations, and established fairs for foreign traders, while he opened up roads, bridges, and canals throughout the country. In his relations with his subjects Gustavus was firm, and sometimes severe, but seldom unjust, except in his dealings towards the Romish clergy, whom he despoiled with something like rapacity of all their lands and funds. On the other hand he did much to promote the cause of Lutheranism; although he took care that the reformed clergy should be dependent on the crown, and enjoy only very moderate emoluments. To him the Lapps were indebted for the diffusion of Christianity among them by Lutheran missionaries; the Finns for the first works of instruction—parts of the Bible and hymn-books printed in their own language. Gustavus was methodical, just, moral, and abstemious in his mode of life—his character altogether admirable but for a touch of avarice. He was three times married, had ten children, and died 29th September 1560, his eldest son, Eric, being his successor according to the treaty of Westerås (1544), which made the crown hereditary. The best memoir is that by Fryxell—Ger. trans. *Leben und Thaten Gustavs I. Wasa* (1831). See also Alberg's *Gustavus Vasa and his Stirring Times* (Lond. 1882), and Paul Barron Watson's book, *The Swedish Revolution under Gustavus Vasa* (1889).

Gustavus III., king of Sweden, was born in 1746, and succeeded his father, Adolph Frederick, in 1771. At that time Sweden was ruled by an oligarchy of the nobles. The first task Gustavus set himself after his accession was to break their power and bring the supreme authority into his own hands; and this task he accomplished by means of a feigned revolt. Being of an energetic temperament and possessing a considerable share of political sagacity, Gustavus now laboured hard, and laboured successfully, for the progress of his

country, encouraging agriculture and bettering the lot of the peasantry, fostering commerce, mining, literature, and science, especially medicine, ordering the finances, digging canals, and building hospitals, orphanages, and workhouses. But he had an inordinate love for things French, and, in his endeavour to imitate the extravagance and splendour of the court of Versailles, he became embarrassed for money. His attempts to overcome this embarrassment by an increase of taxation alienated from him the affections of his people. Of this state of things the nobles took advantage; they thwarted the king's designs in his war with Russia, and endeavoured to recover the power they had lost (see SWEDEN). And, though Gustavus once more broke their opposition and made himself full master of his kingdom, an ill-advised scheme for employing the forces of Sweden in behalf of Louis XVI. of France against the storm of the Revolution led to his own assassination by Ankarström, an emissary of the oligarchical party, at Stockholm in March 1792.

Gustavus IV., king of Sweden, son and successor of Gustavus III., was born 1st November 1778. During the four years of his minority, his uncle, the Duke of Södermanland, acted as regent (1792–96). This king was altogether unfitted to rule a kingdom, owing to his crotchety notions of honour, his obstinate self-will, his exalted ideas of the prerogatives of kingship, and his want of tact and wisdom in the management of public affairs. The ruling principle or motive of his life was hatred of Napoleon. In consequence of this feeling he offended Russia by preferring the alliance with England, lost Stralsund and Rügen to the French, and Finland to the Russians in 1808, made an unsuccessful attack upon Norway, and finally insulted the English by his treatment of an army corps that had been sent to his assistance. In March 1809 the whole of Sweden was in a condition of burning discontent, and a party of nobles, acting in conjunction with the army, dethroned their wholly unpopular sovereign and gave the crown to his uncle, the Duke of Södermanland, who succeeded as Charles XIII. Gustavus spent his last days abroad, chiefly in Switzerland, often in great want, and died at St Gall, 7th February 1837.

Güstrow, a town of Mecklenburg-Schwerin, 70 miles E. by S. of Lübeck by rail. It has a castle (1558–65), a church of the 13th–15th century, and a noticeable pauper school and orphanage, with breweries, iron-foundries, a sugar-factory, tile-works, and a large wool market. It was for nearly a century and a half (1555–1695) the residence of the dukes of Mecklenburg-Güstrow. Pop. (1875) 10,923; (1885) 13,119.

Gut, a term technically used in zoology as equivalent to the enteron or alimentary canal. Three parts have to be carefully distinguished: (*a*) the fore-gut or *stomodæum*, lined by the outer layer or ectoderm, and formed from an anterior infolding or invagination; (*b*) the mid-gut or *mesenteron*, lined by the inner layer or endoderm, and formed from the original gastrula cavity; and (*c*) the hind-gut or *proctodæum*, lined by the outer layer or ectoderm, and formed from a posterior invagination. These three typical parts, thus distinguished according to their origin, vary greatly in size and function in different classes; but the mid-gut is the most important on account of its digestive function and because of its outgrowths (liver, &c.) in higher animals. It must also be noted that in vertebrate anatomy the pharynx, gullet, and stomach are sometimes called fore-gut; the small intestine, mid-gut; the large intestine, hind-gut; but embryologically these are all parts of the mesenteron defined above. See EMBRYOLOGY; and for the gut manufacture, CATGUT.

Gutenberg, JOHANNES, or HENNE, who is regarded by the Germans as the inventor of the art of employing movable types in printing, was born about 1400 at Mainz. He was apparently the illegitimate son of a canon named Gensfleisch, and so adopted his mother's family name. In 1434 he was living in Strasburg, and seems to have been well known as a man of considerable mechanical skill, who taught stone-cutting, mirror-polishing, and similar arts. When and where he made his first attempts in the art of printing cannot with certainty be ascertained. Some time between 1444 and 1448 he returned to Mainz, where, in 1449 or 1450, he entered into partnership with Johannes Faust or Fust, a wealthy goldsmith, who furnished the money required to set up a printing-press. This partnership was, however, dissolved after the lapse of a few years (1455), Faust bringing an action at law against Gutenberg to recover the sums he had advanced. In consequence of the legal verdict Faust retained the printing concern, and carried it on in conjunction with Peter Schöffer of Gernsheim. Gutenberg, with the assistance of a Dr Homery, afterwards set up another printing-press, with which he worked on till the date of his death, 1468. For authorities and an account of the invention controversy, see PRINTING.

Guthrie, SAMUEL, an American chemist, was born in Brimfield, Massachusetts, in 1782. He deserves notice as one of the original discoverers of Chloroform (q.v.), which he termed a 'spirituous solution of chloric ether.' His process was tested as early as 1831. He died at Sackett's Harbour, New York, 19th October 1848.

Guthrie, THOMAS, D.D., an eminent pulpit and platform orator, philanthropist, and social reformer, was born July 12, 1803, at Brechin, Forfarshire, where his father was a merchant and banker. He studied eight years for the ministry at the university of Edinburgh, and devoted two additional winters to the study of chemistry, natural history, and anatomy. Meanwhile he was licensed as a preacher by the presbytery of Brechin in 1825. He subsequently spent six months in Paris, studying comparative anatomy, chemistry, and natural philosophy, and walking the hospitals there. Returning to Scotland, he for two years conducted, on behalf of his family, the affairs of a bank agency in Brechin. After waiting for five years for a presentation to a living, he had almost resolved to abandon the clerical profession when, in 1830, he received a presentation from the crown to Arbirlot, in his native county; and in 1837 was appointed one of the ministers of Old Greyfriars parish in Edinburgh. Here his eloquence, combined with devoted labours to reclaim the degraded population of one of the worst districts of the city, soon won for him a high place in public estimation. In 1840 he was chosen minister of St John's church; he declined calls to London and India. In 1843 Guthrie joined the Free Church, and for a long series of years continued to minister to Free St John's—a large and influential congregation in Edinburgh. In 1845–46 he performed a great service to the Free Church, in his advocacy throughout the country of its scheme for providing manses or residences for its ministers, and raised in less than twelve months £116,000 for this object. Guthrie's zeal, however, was not diverted into mere denominational or sectarian channels. He came forward in 1847 as the advocate of Ragged Schools (q.v.) by the publication of his first *Plea for Ragged Schools*. He was not, as sometimes stated, the founder of the Ragged Schools, but rather the apostle of the

movement. A Ragged School was founded on the Castle Hill, in 1887 removed to Liberton. He also earnestly exerted himself, in many ways, in opposition to intemperance and other prevailing vices, and in favour of national and compulsory education. He became a total abstainer in 1847 through a conversation with an Irish car-driver. Guthrie possessed great rhetorical talent; and his style was remarkable for the abundance and variety of the illustrations he used. Lord Cockburn attributed Guthrie's remarkable influence over his audience to the possession of 'passion and compassion.' Few public speakers have ever blended solemnity and deep pathos so intimately with the humorous, his tendency to which, although never in the pulpit, has more frequently than anything else been pointed out as his fault. Guthrie always displayed a generous sympathy with all that tends to progress or improvement of any kind. He was moderator of the General Assembly of the Free Church of Scotland in May 1862, and one of the vice-presidents of the Evangelical Alliance. He was presented with £5000 in 1865 as a token of public appreciation. He acted as editor of the *Sunday Magazine* from its establishment in 1864, in which year he retired from his regular ministrations. He died 24th February 1873. Guthrie's most important published works are *The Gospel in Ezekiel* (1855); *The Way to Life* (1862); *A Plea for Drunkards and against Drunkenness* (1850); *A Plea for Ragged Schools*, a pamphlet (1847), followed by a second and a third plea, the latter under the title of *Seed-time and Harvest of Ragged Schools* (1862); *The City: its Sins and Sorrows* (1857); *Man and the Gospel* (1865); *Angels' Song* (1865); *Parables* (1866); *Studies of Character* (1868); *Sundays Abroad* (1871). See his *Autobiography and Memoir*, edited by his sons (2 vols. 1874–75); and a small Life by O. Smeaton (1900).

Guthrie, WILLIAM, a political, historical, and miscellaneous writer, was born at Brechin, in Forfarshire, in 1708, and educated at King's College, Aberdeen. At an early period he removed to London, where he worked hard for forty years as a man of letters. He died in March 1770. Among his various works are a *History of England* (3 vols. 1744–50), and *A Historical and Geographical Grammar* (1770; 24th ed. 1827), a useful manual of information, which long enjoyed immense popularity.

Guthrum. See ALFRED THE GREAT.

Guts Muths, JOHANN CHRISTOPH FRIEDRICH, a German teacher, was born at Quedlinburg, in Prussian Saxony, 9th August 1759, studied at Halle, and from 1785 to 1837 taught gymnastics and geography in Salzmann's scholastic institution at Schnepfenthal. He died 21st May 1839. He is specially remembered for having introduced gymnastics as a branch of education in German schools. On this subject and on geography he wrote numerous text-books, as *Gymnastik für die Jugend* (1793) and *Handbuch der Geographie* (1810); he also edited *Bibliothek für Pädagogik* (1800–20) and, along with Jacobi, *Deutsches Land und deutsches Volk* (1820–32). See his life by Wassmannsdorf (Heidelb. 1884).

Gutta-percha, a substance in many respects similar to caoutchouc, is the dried milky juice of various trees of the order Sapotaceæ; the chief is apparently that called by Hooker *Isonandra Gutta*, and by Bentley and Trimen *Dichopsis Gutta*. The tree, which is found in the peninsula of Malacca and the Malayan Archipelago, is very large, attaining a height of 70 feet; the trunk is sometimes 3 or even 4 feet in diameter, although it is of little use as a timber-tree, the wood being spongy. The leaves are alternate, on long stalks, obovate-oblong, entire, somewhat leathery, green above, and of a golden colour beneath. The flowers are in little tufts in the axils of the leaves, small, each on a distinct stalk, the corolla having a short tube and six elliptical segments; they have twelve stamens and one pistil. The name, gutta-percha (*gutta percha*, or *gittah pertja*, is Malay. There are two or three kinds of gutta-percha known in commerce, and it is more than probable these are

Gutta-percha (*Isonandra* (*Dichopsis*) *Gutta*): *a*, a flower; *b*, fruit

yielded by different species. That from Singapore is esteemed the best, and is distinguished by the Malay traders as *Gutta Taban* or *Tuban;* that of Borneo is of less value—this is called *Gutta Percha* by the traders, and has given the general name to all; and another kind goes by the name of *Gutta Girek*. The first two are those generally known in our markets. The former mode of obtaining the gutta-percha was a most destructive one. The finest trees were selected and cut down, and the bark stripped off; between the wood and bark a milky juice was found, which was scraped up into little troughs made of plantain leaves. Now the plan of tapping the living trees is employed. The juice soon coagulates, or may be boiled, and is then kneaded by hand into oblong masses a foot in length.

Gutta-percha was known in Europe long before its peculiar characteristics and uses were known. It was brought home at various times by voyagers, in the forms of drinking-bowls and native shoes; and was thought by some to be a species of india-rubber, while others asserted it was a kind of wood, which they named *mazer-wood*. But for its introduction in 1843 we are indebted chiefly to Dr William Montgomerie of the Indian Medical Service, who was rewarded with the gold medal of the Society of Arts. He first noticed that the Malays used it for making handles to their knives, &c., and it immediately occurred to him that it might be of great use in a variety of ways, especially in making handles for surgical instruments, the hand being able to get a light but firm grasp of them. Soon the importation of gutta-percha increased amazingly; in 1860 it exceeded 16,000 cwt. In 1864, 1865, 1870, and 1871 the imports varied from 25,966 cwt. to 35,636 cwt.; in 1876–83, from 21,100 cwt. to 66,000 cwt. Down to 1888 these imports declined very much, as in that year they only reached 22,500 cwt., at an average price of 162 shillings per cwt. In 1889, however, they showed an upward tendency both in quantity and value, the total imports from January to October 1889 being 38,940 cwt., and the average price 241 shillings per cwt. By far the

greatest portion of it is imported from the East Indies.

Its most important application has been in the coating of marine electric telegraph wires. In this application, as in most others, its inherent defect, arising from the readiness with which it becomes oxidised and decomposed, has manifested itself seriously, and it is greatly affected by age in its resisting qualities. Hence substitutes of greater stability have been looked for. Many of these have been forthcoming, india-rubber being used now to a large extent, as also a composition produced from asphalt, balsam of sulphur, &c., and other compounds. Gutta-percha is used for making a vast variety of useful and ornamental articles. Among others the following may be mentioned: golf-balls (very extensively), overshoes (more in America than in Britain), beltings for machinery, pump-buckets, sheeting, tissue, thread or whip cord, and tubing. A very large trade is done in shoe soles. It is turned by surgeons to various uses, chiefly for splints and moist coverings to retard evaporation. It has also been used for stopping hollow teeth.

The great value of gutta-percha arises from the ease with which it can be worked, and its being so complete a non-conductor of electricity. It softens in warm water, and can be moulded into any form in that state, as when soft it is not sticky and turns well out of moulds. It will always be of great value as a material in which to take casts, as it can in the soft state be made to take the sharpest forms most faithfully; and, as it quickly becomes hard, and preserves its shape if not too thin, the range of its utility in this respect is very extensive.

It is imported in blocks and lumps of five to ten pounds weight, in various forms, chiefly like large cakes, or rounded into gourd-like lumps. It has a very light reddish-brown, or almost a flesh colour, is full of irregular pores elongated in the direction in which the mass has been kneaded. It has a cork-like appearance when cut, and a peculiar cheese-like odour. Before it can be used it has to undergo some preparation. This consists in slicing the lumps into thin shavings, which are placed in a *devilling* or tearing machine revolving in a trough of hot water. This reduces the shavings to exceedingly small pieces, which, by the movement of the tearing-teeth, are washed free from many impurities, especially fragments of the bark of the tree, which, if not separated, would interfere with the compactness of its texture—one of its most important qualities. The small fragments, when sufficiently cleansed, are kneaded into masses; and these are rolled several times between heated cylinders, which press out any air or water, and render the mass uniform in texture. It is then rolled between heated steel rollers into sheets of various thicknesses for use, or is formed into rods, pipes for water, speaking-tubes, or any of the innumerable articles which may be made of it.

Gutta-percha differs very materially from caoutchouc or india-rubber in being non-elastic, or elastic only in a very small degree. Notwithstanding this very striking character of caoutchouc, the two articles are very often confounded in the public mind.

Gutta Rosea, old name for Acne Rosacea (q.v.).

Gutta Serena. See AMAUROSIS.

Guttiferæ, or CLUSIACEÆ, a natural order of exogenous plants, consisting of trees and shrubs, natives of tropical countries, very generally secreting an acrid yellow resinous juice. A few are epiphytes. The leaves are opposite, destitute of stipules, leathery, and entire. In botanical characters this order is allied to Hypericinæ. It contains about 150 known species, the greater part of them South American, although all tropical countries produce some. The resinous secretions of some are valuable, particularly of those trees which yield Gamboge (q.v.) and Tacamahaca (q.v.). See also CLUSIA.—A few species afford valuable timber. See CALOPHYLLUM.—The flowers of some are very fragrant; those of *Mesua ferrea* are found in a dried state in every bazaar in India, and are used as a perfume.—The fruit of some is very highly esteemed; the Mangosteen (q.v.) has been described as the finest fruit in the world. The Mammee Apple (q.v.) is another of the most celebrated tropical fruits.

Gutzkow, KARL FERDINAND, German writer, born at Berlin, 17th March 1811. Whilst preparing for the calling of gymnasium teacher he became profoundly influenced by the French Revolution of 1830, and in 1831 he joined the critic Menzel in Stuttgart, and helped him to edit the *Litteraturblatt*. This his introduction to serious literary work led to the publication in 1832 of the satirical romance *Maha-Guru*, and in 1835 of *Wally, die Zweiflerin*. For this last Gutzkow was imprisoned for three months, his book being confiscated and himself forbidden to publish any work within the states of the Confederation—the author having revealed himself in his book as an ardent champion of the 'Young Germany' movement, the object of which was to oppose romanticism and advocate in place of it all those revolutionary ideas which are in their character essentially and peculiarly modern. As soon as he obtained his release he entered upon a period of restless and migratory activity as a journalist, until in 1847 he became director of the Court Theatre at Dresden. In the meantime he had written some successful dramas, *Richard Savage* (1839), *Zopf und Schwert* (1844), *Das Urbild des Tartüffe* (1847), *Uriel Acosta* (1847), besides *Werner, Ottfried, Der Königsleutnant*, and many others which won only dubious recognition. He also wrote some romances of considerable merit, as *Die Ritter vom Geiste* (9 vols. 1850–52), *Der Zauberer von Rom* (9 vols. 1858–61), *Hohenschwangau* (5 vols. 1867–68), and *Kleine Narrenwelt* (1856), a collection of short stories. In 1864 Gutzkow, whilst suffering from a nervous mental disorder, made an unsuccessful attempt upon his own life. This malady returned in 1873, and after a visit to Italy he settled at Sachsenhausen, near Frankfort-on-Main, where he died, 16th December 1878. Gutzkow possessed a keen instinct for the spiritual fermentations and conflicts and the intellectual problems of his time, and in his literary productions could not sufficiently subordinate his interests to the proper canons of art. These didactic and critical phases of his temperament spoil most of his best books, except perhaps *Uriel Acosta*. Apart from this failing, and the great length of some of them, those same books exhibit much excellent character drawing, much keen analysis of motives, a penetrating insight into the tendencies of current thought, clever dialogues, and skilful and dramatic arrangement of situations and scenes. His *Gesammelte Werke* have been issued in 32 vols. (Jena, 1873 *sq.*).

Gützlaff, KARL FRIEDRICH AUGUST, German missionary to China, was born at Pyritz, in Pomerania, 8th July 1803. Going out to the East under the auspices of the Dutch Missionary Society, he spent two years in Batavia learning Chinese. Then, in 1828, he proceeded to Bangkok, capital of Siam, where he translated the Bible into Siamese. Finally, in 1831, he reached the goal of his aspirations—China. During the rest of his life he lived mostly at Macao and Hong-kong, occupying himself with a translation of the Bible into Chinese, with

writing various books in Chinese, German, and English, with publishing a monthly magazine in Chinese, and above all (from 1844) with the training of native preachers to carry the gospel into the interior, for at that time foreigners were not allowed to enter the empire. He rendered valuable assistance to the British during the war of 1840-42 and the subsequent negotiations for peace. He died at Hong kong, 9th August 1851. He published a *Journal of Three Voyages along the Coast of China* (Lond. 1834; Ger. trans. 1835); *China Opened* (1838); *The Life of Tao-Chang* (1838); and a history of China in German (1847), besides addresses, reports, &c.

Guy, Thomas, founder of Guy's Hospital (q.v.), Southwark, London, the son of a lighterman and coal-dealer, was born in Fair Street, Horselydown, near the Thames, in 1644. He began business in 1668 in the angle formed by Cornhill and Lombard Street, as a bookseller with a stock of about £200, dealing extensively in the importation of English Bibles from Holland (those printed at home being executed very badly); and, on this being stopped, he contracted with the university of Oxford for the privilege of printing Bibles, which he continued to do for many years. By this means, and by selling out his original shares in South Sea Stock at a great advantage, he amassed a fortune of nearly half a million sterling. In 1707 he built and furnished three wards of St Thomas's Hospital. For the building and endowment of the hospital in Southwark which bears his name he set apart £238,295, 16s. He was also a liberal benefactor to the Stationers' Company, and built and endowed almshouses and a library at Tamworth, for which he became one of the members about 1694. Besides bestowing £400 a year on Christ's Hospital, and giving to various other charities, he left £80,000 to be divided among those who could prove any degree of relationship to him. He was of mean appearance, with a melancholy countenance, and was regarded as an intensely selfish and avaricious man. He died December 27, 1724.

Guy de Lusignan. See Cyprus.

Guy of Arezzo. See Guido Aretinus.

Guy of Warwick, the hero of one of the most ancient and popular of our early English metrical romances. It is a purely English story of the 13th century, related to the Dano-Saxon romance of *Havelok* by its allusions to Danish wars in England, and to the French *King Horn* by its adoption of some of the more striking incidents in that story. Its authorship may be due to Walter of Exeter, a 13th-century Franciscan monk, but it has undoubtedly been improved by some French or Norman minstrel. The story has close affinity with that of Guido Tyrius in the *Gesta Romanorum*. The hero, Sir Guy of Warwick, is son of Segard, steward of Rohand, Earl of Warwick; his instructor in the exercises of chivalry, the famous Héraud of Ardenne. Having fallen deeply in love with Felice, the fair and accomplished daughter of the earl, he fell into a grievous sickness, but was recalled to life by a promise of her hand when he had earned it by knightly deeds. Immediately he crossed to Normandy, at the great tournament of Rouen vanquished every competitor, and at once set out into far lands, travelling through Spain, Almayne, and Lombardy, and gaining the prize in every tournament. He then returned to England, and overcame the famous Dun Cow on Dunsmore Heath, near Warwick. But his haughty mistress was still unsatisfied. Once more he left his country to traverse Flanders and Italy, and here he well-nigh lost his life through the treachery of Otho, the 'felon duke' of Pavia. He next went to Constantinople to save the Emperor Ernis from the Saracens, slew the mighty Coldran, cousin of the soudan, and scattered his huge army. The grateful emperor pressed on him the hand of his lovely daughter and heiress Loret, but, faithful to Felice, Sir Guy tore himself away, and returned, with many adventures by the way, to his native country. No sooner had he reached its shores than tidings were brought of a most portentous dragon then ravaging Northumberland. He hastened to meet the monster, slew him, and carried his head to King Athelstan, at Lincoln. The fair Felice had now no scruple to marry the hero. But remorse for all the slaughter he had done merely for a woman's love began to seize him, and after forty brief days of wedded happiness he left his home in the dress of a palmer to visit the Holy Land. Here he rescued Earl Jonas from his dungeon, and slew the ferocious giant Amiraunt, after which he returned to England to find Athelstan besieged in Winchester by the Danish Anlaf, of whose army the mainstay was the terrible Colbrand. Sir Guy, still in his disguise, after a prolonged and awful struggle, succeeded in striking off the champion's head. He now visited his wife all unknown in his palmer's weeds, and then retired to a hermitage at the place still called Guy's Cliff, near Warwick. Before his death he sent her parting ring as a token to Felice, and she arrived in time to close his eyes, survived him for but fifteen days, and was buried in the same grave.

An edition in French prose was printed at Paris in 1525; the earliest English edition is undated, but most probably appeared about 1550. The earliest English MS., that of Auchinleck, was printed for the Abbotsford Club in 1840; and again, together with the Caius MS., by Professor Zupitza for the Early English Text Society (1883-87). A 15th-century version had already been edited for the same society by Zupitza (1875-76). All these MSS. have most probably been translated from the Anglo-French version. See J. Zupitza, *Zur Literaturgeschichte des Guy von Warwick* (Vienna, 1873); A. Tanner, *Die Sage von Guy von Warwick* (1877).

Guyon, Jeanne Marie Bouvieres de la Mothe, French mystic, was born at Montargis (dept. Loiret), 13th April 1648. She had destined herself for the cloister, but was married, when sixteen years of age, to Jacques Guyon, a man of great wealth, but much older than herself. Being, however, left a widow at twenty-eight, she determined to devote her life to practical ministrations to the poor and needy, and to the cultivation of spiritual perfection, or an endeavour to realise the consummate achievements of the inner life, for herself. The former part of her plan she began to carry out in 1681 in the neighbourhood of Geneva, where she found a sympathetic coadjutor in Father La Combe. But three years later she was compelled to depart thence on the ground that her Quietist doctrines were heretical (see Quietists). At Turin, Grenoble, Nice, Genoa, Vercelli, and Paris, where she finally settled in 1686, she became the centre of a religious movement for the encouragement of 'holy living.' But in January 1688 she was arrested for having taught heretical opinions, and for having been in correspondence with Molinos, the leader of quietism in Spain. Released by the intervention of Madame de Maintenon, after a detention of nine months, she soon afterwards became acquainted with Fénelon; but, her influence spreading, she was again imprisoned in 1695. Out of a commission appointed to inquire into her teachings and conduct of life arose a controversy between Fénelon (q.v.) and Bossuet. Madame Guyon was not released from the Bastille until 1702. The remainder of her life was spent in retirement at Blois, where she died, 9th June 1717. Her views find best expression in her works entitled

Les Torrens Spirituels, *Moyen Court de Faire Oraison*, and *Le Cantique des Cantiques interprete selon le sens mystique*. She also wrote an autobiography and letters, as well as some spiritual poetry. Her collected works appeared in 40 vols. in 1767-91. See Upham, *Life and Religious Opinions of Madame Guyon* (New York, 1847), and Guerrier, *Madame Guyon* (Orleans, 1881).

Guyon, Richard Debaufre, a general in the Hungarian revolutionary war, was born at Walcot, near Bath, 31st March 1813. His father, a commander in the English navy, was the descendant of a Huguenot family that settled in England after the revocation of the Edict of Nantes. Guyon entered the Austrian service in 1831; and married the daughter of a Hungarian baron and field-marshal in 1838. From that time till the outbreak of the revolution, Guyon led the life of a country gentleman on his estates near Komorn, but was one among the first to offer his services to the national government, and acted a prominent part in the struggle for independence. During the retreat of Görgei's army, Guyon carried the mountain-pass of Branyiszko, and by that daring feat re-established the communication with the government at Debreczin, as also with the several other Hungarian army corps. He did brilliant service at Kapolya, Komorn, and elsewhere; and after the end of the war escaped to Turkey, and entered the service of the sultan, without being obliged to turn Mohammedan. Under the name of Kourshid Pasha, he, as a general of division, was governor of Damascus, and at the beginning of the Crimean war did much to organise the army of Kars. He died at Constantinople, 12th October 1856. See A. Kinglake, *General Guyon* (1856).

Guyot, Arnold, geographer, was born in Switzerland in 1807, took the degree of Ph.D. at Berlin in 1835, was the colleague of Agassiz at Neuchâtel in 1839–48, and in 1848 accompanied him to America. Guyot delivered a course of lectures at the Lowell Institute, which were translated by Professor Felton (q.v.), and published as *Earth and Man* (1853). In 1854 he was appointed professor of Physical Geography and Geology at Princeton, where he died, 8th February 1884. He had the management of the meteorological department of the Smithsonian Institution, where he more than once delivered courses of lectures, and in connection with which he published *Meteorological and Physical Tables* (revised ed. 1884). Guyot was joint-editor of *Johnson's Cyclopædia* (1874–77), and his other works include several biographies, a *Treatise on Physical Geography* (1873), and a series of geographies and wall-maps which are in general use in American schools.

Guy's Hospital was founded by Thomas Guy (q.v.), who leased from the governors of St Thomas's Hospital a large piece of ground, for a term of 999 years, at a ground-rent of £30 a year. The space being cleared, the first stone of the building was laid in 1722, and the hospital admitted its first patient in 1725, a few days after the death of its founder. The whole expense was £18,796, 16s., great part of which Guy expended in his lifetime, and he bequeathed £219,499 to endow it. Soon after his death an act of parliament was obtained, regulating the management of the institution. In 1829 Mr Hunt bequeathed to the hospital £190,000, and additional bequests to the amount of £10,000 have since been received. There was at first room for about 400 patients; now 700 can be accommodated. The yearly average of patients is over 5000; the out-patients relieved may amount to above 80,000. The annual income is about £40,000, chiefly from estates in the counties of Essex, Hereford, and Lincoln. The usual number of governors is sixty, who are self-elective. Students enter the hospital for study, attending clinical practice, lectures, &c., and paying annual fees. The building consists of two quadrangles, united by a cross structure or arcade, besides two wings extending from the front to the street—west wing built with elegance and uniformity, and whole edifice handsome and regular. A library and valuable museums are attached to the hospital. New wards, with tall towers for ventilation, were built in 1852, and a chemical laboratory in 1872. In the chapel is a fine marble statue of Guy, by Bacon, which cost £1000. Sir Astley Cooper is buried in the chapel. See the *History of Guy's Hospital* by Wilks and Bellamy (1893).

Guzerat. See Gujarat.

Guzman Blanco, Antonio, was born in Caracas in 1830, was banished for his share in political disturbances, and, after taking a prominent part in two invasions, became vice-president of Venezuela in 1863. Driven from office in 1868, he headed a revolution which restored him to power in 1870, and for many years he was virtual dictator of the country; other men were occasionally permitted to fill the position of president, but they were merely figure-heads. In 1889, however, popular discontent was aggravated by reports of corrupt contracts made in Paris; and Blanco, who was then acting as envoy to all the European powers, was practically deposed by congress, which refused to accept the resignation of his former protegé and present rival, Dr Rojas Paul. For Guzman Blanco state, see Cura (Ciudad de).

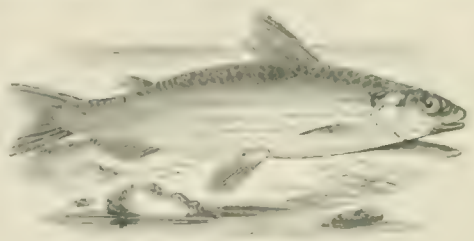
Gwalior, a native state of central India, the dominions of the Mahratta Maharajah Sindhia (q.v.), consists of several detached districts, with an area of 29,046 sq. m., lying principally between 23° 20′ and 26° 52′ N. lat., and in 76° 15′ to 79° 12′ E. long. Lying partly in the basin of the Jumna and partly in that of the Nerbudda, it divides its drainage between the Bay of Bengal and the Arabian Sea. The principal export is opium. At the census of 1881, the first attempted, the population was 3,115,857; in 1891, 3,378,774, mainly Hindus. Though Gwalior is a Mahratta principality, being, in fact, the principal fragment of the great empire of the Peshwa, yet the Mahrattas do not form any considerable proportion of the people, and are said to number only 15,000. The revenue of the state is estimated at £1,200,000; the strength of the army is fixed at 6000 cavalry, 5000 infantry, and 48 guns, and there are nearly 7500 police. Since 1803 the country has been under British protection. In 1843 the British were compelled, on the death of the sovereign, to send an armed force, which, after severe fighting, succeeded in restoring his adopted successor to the throne; and during the troubles of 1857 the young Maharajah remained faithful to the British government, although deserted by his troops.—Gwalior, the capital, stands 65 miles S. of Agra by railway. Its nucleus is an isolated rock of about 340 feet in height, perpendicular, either naturally or artificially, on all sides; it measures 1½ mile by 300 yards, and its citadel (said to date from the 8th century), whose guns sweep the only approach, is virtually impregnable against any native force. Along the eastern base of this eminence lies the old town of Gwalior, containing little worthy of notice but a beautiful mausoleum of white sandstone; and to the south-west there extends for several miles the new town called Lashkar, where the Maharajah resides. Nearly 4 miles to the north-east is Morar, the British cantonment from 1858 to 1886, when its fine sandstone barracks were handed over, along with the fortress, to Sindhia, and the European headquarters removed to Jhansi.

There are Hindu temples, a Hindu palace, Jain caves, and rock sculptures. Pop. (1891) 104,083.

Gweedore, a hamlet in a poverty-stricken district 3 miles inland from the west coast of Donegal, 28 miles NW. of Letterkenny.

Gwillim. See GUILLIM.

Gwyniad (*Coregonus clupeoides*), a small fresh-water fish, sometimes called the *Fresh-water Herring*. When full grown the gwyniad is about 10 or 12 inches in length; the first dorsal fin is high; the jaws are a little produced; the mouth is small, and the jaws are without teeth. It is found



Gwyniad (*Coregonus clupeoides*).

in some of the Lakes of Wales and Cumberland. Gwyniad is a Welsh name, while at Ullswater the fish is called *Schelly*. It occurs in that lake in great shoals, so that many hundreds are sometimes taken at a single draught of the net. It is rather an insipid fish, and cannot be kept long after being taken out of the water, unless salted, which it often is by the poor. There are numerous nearly-related species, such as the Irish 'pollan' (*C. pollan*), the 'powan' of Loch Lomond, the 'vendace' (*C. vandesius*) of Lochmaben, and the 'white fish' of North American lakes. See COREGONUS.

Gwynn, NELL. See CHARLES II.

Gyarmat-Balassa, or BALASSA-GYARMAT, a town of Hungary, 40 miles N. by E. of Pesth. Here peace was concluded between Austria and Turkey in 1626. Pop. 6788.

Gyges, king of Lydia, who obtained the throne by murdering his master, king Candaules, and marrying his widow. This happened about 687 B.C. Gyges reigned thirty-four years, during the course of which he wrested Magnesia and Colophon from the Ionian Greeks, lent assistance to Psammetichus in his revolt in Egypt against Assyria, and, after stoutly defending himself for some time against the Cimmerians, was at last slain by them (654 B.C.). Plato has a fable in which Gyges, having miraculously obtained possession of a golden ring of great virtue, was enabled by means of it to make himself invisible, and thus took occasion to murder his sovereign and usurp the supreme power.

Gymnasium. This word from *gymnos*, 'naked') was applied to those public places or buildings where the Greek youths exercised themselves, fitted up with running and wrestling grounds, baths, and rooms or halls for conversation and discussion. These were the favourite resort of youth, and for this reason were frequented by teachers, especially philosophers. The three great gymnasia of Athens were the Academy, where Plato taught; the Lyceum, where Aristotle laboured; and the Cynosarges. In this connection it is easy to understand the transference of the name to institutions for the mental disciplining and instruction of youth. The German gymnasium is an upper school where instruction is carried out largely by means of the classical tongues, preparing its pupils for the university, and corresponding roughly to the grammar and public schools of England, and the grammar and high schools of Scotland. See EDUCATION, Vol. IV. p. 208.

Gymnastics. According to the derivation and original use of the word Gymnastics (*gymnos*, 'naked or stripped') all athletic exercises might be included under this head, but the term is now much more restricted in its application. It excludes athletic sports, and all outdoor games such as cricket, football, and lawn-tennis, and is limited to certain exercises devised to strengthen the muscles and bones, especially those of the upper half of the body.

Gymnastic games in their original sense are so old as to be prehistoric; they are alluded to in the 2d and 23d books of the *Iliad*. Before the time of Hippocrates gymnastic exercises had been adopted in Greece as part of the course of medicine intended to counteract increasing luxury and indolence. The various exercises were speedily combined into a system, and gymnasia, where they should be practised, were formed first by the Lacedæmonians, and subsequently at Athens. The Romans adopted the system, and constructed gymnasia on a magnificent scale. Many of their buildings, having extensive baths attached, were known as *thermæ*. The exercises in the gymnasia consisted of running, leaping, dancing, wrestling, boxing, hurling, &c.; and in those days, when all men bore arms, and when, in close combat, victory went generally to the strongest man, these games were doubtless of great value. In subsequent ages of knightly prowess similar exercises were probably practised, though less publicly; but with the introduction of gunpowder, and through its means, the gradual substitution of fighting at a distance—in which science and skill were the main requisites—for personal encounters where strength and muscle went far to carry the day, the attention paid to gymnastics decreased, and finally vanished altogether. To make infantry soldiers perfect in the drilled movements of masses, cavalry soldiers good horsemen and fair swordsmen, and to have gunners who could take an accurate aim became the utmost sought by the possessors of great armies; while the science of gymnastics, having gone out of repute for the military, was speedily neglected in merely civil life. It is only since the earlier portion of the 19th century that the science has at all revived.

The revival commenced in Germany, where, in 1774 and 1784, gymnasia were opened by Basedow (q.v.) and Salzmann at Dessau and Schnepfenthal in Thüringen, that of the latter being under the superintendence of the celebrated gymnastic pedagogue Guts Muths (q.v.). In 1811 Friedrich Ludwig Jahn (1778–1852), the so-called 'Turnvater,' or father of gymnastics, opened the first 'turnplatz' at Berlin, and he rendered the science of gymnastics so popular that it speedily attracted the attention of the youth throughout the kingdom, and to the training thus obtained must be attributed, in no small degree, the vigour which succeeded in driving out the French army of the first empire. Sweden soon imitated Prussia, and from that time gymnastics has formed a prominent feature in the Scandinavian course of education. In Prussia the gymnasia began to be the scenes of political gatherings, too liberal in tendency to please its semi-military government; and in 1818 they were all closed. The troops were, however, continued in gymnastic exercises, and showed so clearly the advantages of the training they experienced that, about 1844, Louis-Philippe adopted and improved the system in the French army. From that time gymnasia have been constructed for almost all continental armies, and, with more or less success, for the civil population. England moved publicly in the matter in 1860, in which year Major (afterwards Major-general) Hammersley, the 'father of

military gymnastics,' was sent to Oxford to be trained in Mr MacLaren's gymnasium, and the gymnasia at Aldershot and other stations were then built and placed under his superintendence. In private life, however, there had long been many excellent gymnasia, one of the best and earliest being that opened at Oxford by the late Archibald MacLaren in 1858.

Gymnastic exercises may be divided into two great groups, those conducted without and those conducted with apparatus, while the latter group may be again subdivided into those requiring movable apparatus and those requiring immovable apparatus—i.e. so far as the gymnast is concerned.

Exercises without apparatus have been specially studied in Sweden, and there chiefly by Professor Ling (1776–1839), whose name is generally associated with them in England. By various movements of the arms, trunk, and lower limbs, singly or combined, every muscle in the body can be brought into play, and all that is required for keeping the body in health can thus easily be practised. In schools these movements have often been carried out with great advantage between lessons, giving the children that exercise which their growing frames demand, and thus avoiding restlessness, which is the natural result of enforced quiet. When a number of children work together, and especially when in time to music, the interest of the practice is greatly increased. For further information the reader may consult Dr Roth's account of the Ling system (1864), or Ling's *Swedish Gymnastics* (Lond. 1885). So important are these exercises without apparatus considered in the army that a series of them, known as 'Extension Exercises,' have been laid down in the ordinary *Field Exercise Drill-book*, and in the 1888 edition of this work they have been carefully reconsidered and improved.

Next in simplicity are gymnastic exercises with movable apparatus—i.e. such as weights and bars. Of these, the commonest forms are dumb-bells, bar-bells—i.e. bars about 3 feet long with a weight at either end—and Indian clubs. The arms and shoulders can be made to do any amount of work with these, according to the weights employed, and, if so desired, many of the exercises of the first group designed for the trunk and lower limbs may be carried out while dumb-bells or bar-bells are held in the hands, thus materially increasing the work done. The weight of any or all of these should be carefully suited to the strength of the individual, otherwise more harm than good may result from their use.

The forms of apparatus required for the last group of exercises are numerous, but only a few are really essential. Thus we have the horizontal bar, capable of being placed at any desired level between 3 and 10 feet; and parallel bars—i.e. two bars about 30 inches apart, and fixed about 4 feet from the ground. With these almost as much exercise as may be wanted can be obtained. But in most gymnasia there are, besides, iron rings hung by ropes from the roof, a trapeze-bar also hung from the roof, ladders horizontal at some distance above the floor and vertical, climbing poles and ropes, and various pulleys with weights attached for exercising the wrists and shoulders.

It is advisable that beginners working in a gymnasium should be under the direction of an instructor, who will be able to graduate their exercises, so as to avoid any overstraining. Light and loose flannel clothing should in all cases be worn.

The special value of gymnastics lies in their exercising the arms, shoulders, and chest. On this account they are particularly valuable for all who lead sedentary lives, and also as an important auxiliary for those who wish by athletic exercises to perfect their muscular development.

The system of gymnastics adopted in the British army is a thorough one, and is well calculated to develop the frames of recruits, as well as to harden and strengthen those of the drilled men. The course begins with the use of movable apparatus, after which the trunk and lower limbs are exercised by walking, leaping, and vaulting; next the muscles of the arms and of the trunk are brought out by exercises on the trapeze and parallel bars. Then the muscles of the whole body are developed by various climbing exercises on poles, ropes, and ladders; and, lastly, the training is brought to a practical bearing by escalading practice. In order to improve respiration running drill has also been instituted.

The theory of the advantage derivable from gymnastics is simple enough. An admirable law of nature provides that—within certain limits—parts of the human frame increase in strength, aptitude, and size in proportion to the use made of them. In gymnastics this law is brought to bear successively on every part, and finally on the whole system in combined action. If the exertion be not carried so far as to induce excessive fatigue, all other parts of the body sympathise with the improving condition of that which is mainly exerted; the circulation, excited from time to time by the exercise, acquires fresh vigour, and, blood being driven with unwonted force into all parts of the system, every function is carried on with increased activity. An improvement in the general health soon becomes manifest, and the mind—if simultaneously cultivated with judgment—increases in power and endurance.

See Captain Chiasso's *Gymnastics and Calisthenics*; G. Roland's *Gymnastics*; Walker's *British Manly Exercises*; and MacLaren's *Training, its Theory and Practice*, and *Physical Education, Theoretical and Practical* (1868). The books written in German on Gymnastics ('Turnkunst') would form a small library.

Gymnema. See COW-PLANT.

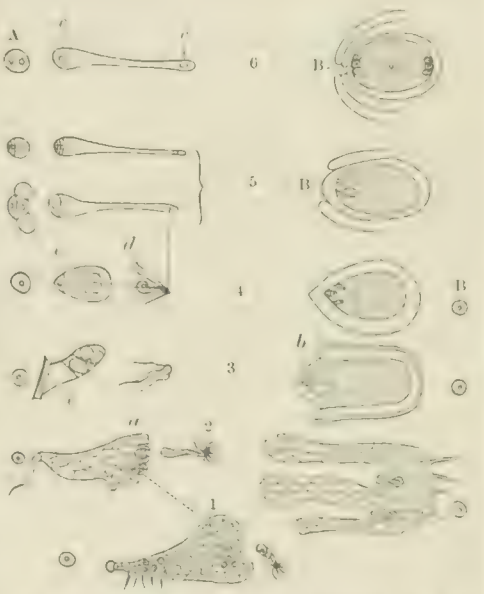
Gymnocladus, a genus of trees of the natural order Leguminosæ, sub-order Cæsalpiniæ. *G. Canadensis* is a North American tree, found both in Canada and over a great part of the United States, attaining a height of 50 to 60 feet, with branches remarkable for their upright direction, and an exceedingly rough bark which comes off in slips. The leaves of young trees are very large, three feet long, bipinnate, armed with thorns. The flowers are white in short spikes. The pods are five inches long by two broad. The tree is called *Chicot* in Canada, and sometimes *Stump Tree*, from its dead appearance in winter, and the absence of conspicuous buds. It is also called the *Kentucky Coffee Tree*, because the seeds were formerly roasted and ground as coffee in Kentucky. It grows well in Britain. The wood is used both by cabinet-makers and by carpenters. It has very little sap-wood. The pods, preserved like those of the tamarind, are said to be wholesome and slightly aperient.

Gymnogens, Lindley's term, now obsolete, for the Gymnosperms (q.v.).

Gymnosomata. See PTEROPOD.

Gymnosophists (i.e. 'naked sages'), the name given by the Greeks to those ancient Hindu philosophers who lived solitarily, wore little or no clothing, and addicted themselves to mystical contemplation and the practice of the most rigorous asceticism. Some, like Kalanus, even burned themselves to death in order to enter a state of purer being. Strabo divides them into Brahmans and Samans, the former of whom adhered to the strictest principles of *caste*, while the latter admitted any one into their number regarding whose character and kindred they were satisfied.

Gymnosperms (Gr. *gumnos*, 'naked;' hence the name Gymnosperms, 'naked seeded' plants), the lower or more primitive group of seed plants (Phanerogams, q.v.), differ in many points from the higher group, the Angiosperms. The chief differences are summarised in the article Angiosperms (q.v.). Gymnosperms consist of the orders Cycadaceæ (q.v.), Coniferæ (q.v.), and Gnetaceæ (see SEA-GRAPE). Although these orders do not resemble one another externally, their morphological characters and mode of sexual reproduction are very similar. In *structure* their stems resemble those of Dicotyledons (q.v.); the secondary wood is formed in concentric rings from permanent cambium, contains tracheides with bordered pits, but no true vessels; and secretory passages are present in most stems, containing resin in conifers and gum in cycads. It is, however, from their mode of sexual reproduction that we are able most clearly to assign their place among plants, as a connecting link between the higher cryptogams and angiosperms.



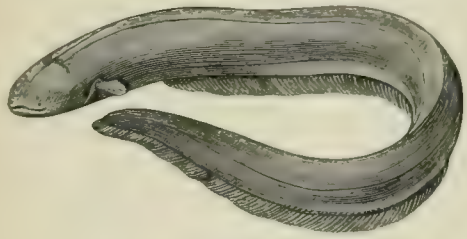
1, The fern-sporophyte (fern-Prothallus contrasted with male (or male [illegible]) Prothalli of Equisetum; 2 shows the corresponding relations of the sexual prothalli in 3, Salvinia; 4, Isoëtes; 5, Cycas; and Conifer; and 6, many Angiosperms. A, fertile segment of sporophyte; *c*, male pronucleus; *d*, spermatozoid; *e*, male prothallus. B, male spores.

In gymnosperms we first meet with an organ which is morphologically, and at the same time physiologically, a Flower (q.v.). The *flowers* are unisexual; and the plants either monœcious or diœcious; while hermaphroditism prevails among Angiosperms. The male flowers are *stamens* bearing *pollen-sacs*, which develop free unicellular *pollen-grains;* those three sets of structures being respectively the homologues of sporophylls, microsporangia, and microspores of cryptogams. Each pollen-grain divides into a large reproductive cell and one or more vegetative cells (the male prothallus of higher cryptogams). Each cell has a nucleus, and that of the reproductive cell, the *male pronucleus*, is the homologue of the spermatozoid of cryptogams. When the stamens are matured, the sacs open; the grains are shaken out, and some are borne by the wind to the surfaces of ripe ovules (macrosporangia of cryptogams). When a pollen-grain reaches an ovule it begins to germinate, its coat ruptures, the reproductive cell grows at the expense of the vegetative to form a *pollen-tube* (antheridium of cryptogams) which ultimately penetrates the nucellus of the ovule, and its pronucleus fertilises the pronucleus of the oosphere (see FERN). This is a step in advance of the higher cryptogams, for their microspores are shed from the parent plant, and germinate only in a substratum where they develop into prothalli-bearing antheridia from which spermatozoids are eventually set free. The microspores of *Salvinia natans*, a heterosporous fern, form the only exception, because they develop prothalli and antheridia within the sporangium. Spermatozoids can fertilise only with the help of water; while pollen-grains of gymnosperms are carried by the wind to the female flowers.

In gymnosperms, then, we have a very marked transition in the process of fertilisation. Spermatozoids readily pass down the neck canals of archegonia and so reach the oosphere, but they would be unable to pierce the nucellus of gymnosperms; hence the necessity of a slow-growing pollen-tube in the latter. The female flower is a macrosporangium borne at the end of an axis or shoot, or a carpellary leaf (sporophyll), with a macrosporangium in its axil, on its upper surface, or on its margin. The ovule has never more than one coat; while in many angiosperms there are two. Further, the carpellary leaves never unite to form an ovary round the ovule, which, therefore, remains naked (hence the name); in angiosperms the ovules are always enclosed in ovaries. The ovule is filled at first with a mass of tissue, the *nucellus*, in which is afterwards developed the *embryo-sac* or mother-cell (macrospore of cryptogams); this sac forms within itself a prothallus (also called endosperm of phanerogams) which develops at its anterior end several archegonia (see FERN, fig. 2). The endosperm of gymnosperms is formed before, that of angiosperms after fertilisation. Inside each archegonium is an oosphere which, after fertilisation of its pronucleus by the male pronucleus, develops the embryo. Part only of the oosphere forms the embryo, the rest forms a kind of nutritive yolk, thus resembling the eggs of many animals. This is the only example of meroblastic segmentation of the ovum in the vegetable kingdom (see EMBRYOLOGY). The embryo lies straight in the prothallus, and never curved as in many angiosperms. Concealment of alternation of generations thus takes place for the first time in gymnosperms. In vascular cryptogams there are two distinct sets of individuals—viz. the asexual (sporophyte generation) represented by the fern-plant, and the sexual (oophyte generation) represented by the minute fern-prothallus. The sexual individuals of cryptogams, with the exception of the microspores of Salvinia, lead independent lives for a time; but those of phanerogams are parasitic on the parent plant; and as parasitism leads to degeneration of parts, so we have the prothalli in gymnosperms reduced, and still more reduced in angiosperms. The evolution of plant-forms has thus been a progressive increase of the sporophyte generation at the expense of the oophyte, and this is in harmony with the characteristically anabolic nature of plants. See Goebel's *Morphology of Plants*, Sach's *Physiology of Plants*, and Vines's *Physiology of Plants*.

Gymnotus, or ELECTRIC EEL (*G. electricus*), the most powerful of the electric fishes, occurs in the fresh water of Brazil and Guiana. It is type of a family Gymnotidæ among the Physostomatous bony fishes, but is the only known species of its genus. There are no dorsal nor strictly caudal fins, but the anal fin extends on to the end of the tail; there are no scales, and the eyes are very small. The fish attains a length of 6

feet, and is capable with its shock of temporarily paralysing a man or large animal, or of killing its



Electric Eel (*Gymnotus electricus*).

prey of fishes and amphibians. For description of the electric organs, see ELECTRIC FISHES.

Gympie, a town of Queensland, 61 miles by rail S. of Maryborough. The gold-reefs round yielded in 1867–94 a total of about 1,800,000 oz. Pop. 8449,

Gynæcology, that branch of Medicine which treats of the diseases of women.

Gynocardia, the chaulmugra tree, whose seeds yield an oil highly valued in India and China as a remedy in leprosy and skin diseases.

Gyöngyös, a town of Hungary, at the southern base of the Matra Mountains, 59 miles by rail NE. of Pesth. It has mineral baths. Pop. 15,896.

Gyp, the pseudonym under which the Countess Gabrielle de Martel de Janville born Riqueti de Mirabeau, and the last of that famous stock—has written a long series of unconventional and anti-conventional novels, including *Petit Bob* (1882), *Autour du Mariage* (1893), *Elles et Lui* (1885), *Ohe! les Psychologues* (1892), *Mdlle. Eve* (dramatised in 1895), *Pas Jaloux* (1895), *Lewis Ames, Les Bons Normands!* &c. *Chiffon's Marriage* (1894: translated 1895) was greeted as her masterpiece.

Gypaëtos. See LÄMMERGEIER.

Gypsies, a wandering race, dispersed the wide world over, and distinguished by language, physique, and mode of life. Their number in Europe is vaguely estimated at 700,000; and only for the following countries have we these more or less trustworthy statistics: Hungary (1890) 95,157; Bosnia and Herzegovina (1874), 9537; Servia (1890), 37,581; Roumania (1895) 200,000; Bulgaria and Eastern Roumelia (1893), 51,754; the vilayet of Adrianople (1876), 27,326 males; Russia (1877), 11,654; Prussia (1887), 1054 *settled* Gypsies. Asia has untold thousands of these nomads, in Anatolia, Syria, Armenia, Persia, Turkestan, and Siberia; so, too, has Africa, in Egypt, Algeria, Dar-Fûr, and Kordofan. We find them in both North and South America, from Pictou in Canada to Rio in Brazil; nor are even New Zealand and Australia without their isolated bands.

Late in 1417 four hundred 'Secani' arrived from the East at Lüneburg, and thence passed on to Hamburg, Lübeck, Wismar, Rostock, Stralsund, and Greifswald. In 1418 they are heard of at Leipzig and Frankfort-on-the-Main, in Switzerland, and at Augsburg; in 1419 at Mâcon and at Sisteron in Provence; in 1420 at Deventer: in 1421 at Tournai; in 1422, *en route* for Rome, at Bologna and at Forli, where 'some said they were from India;' in 1427 at Paris; and so on till in 1433 we lose sight of them for a while in Bavaria. Oftenest they seem to have bivouacked in the fields, but at Deventer they slept in a barn, at Bologna 'lodged themselves inside and outside the gate of Galiera, and settled themselves under the porticoes, with the exception of Duke Andrew, who lay at the King's Inn.' Some riding and some afoot, with the women and children in wagons, they were led by him or Duke Michael, or by both together, according as the band, 400 to 1400 strong, split up or reunited. These two chieftains and certain subordinate 'counts' went richly dressed, with fine silver belts, and, like nobles, led dogs of chase; but the rest of the 'Egyptians,' 'Saracens,' or 'baptised heathens' are described as lean, hideous, black as Tartars, poor, and pitiful. They lived on charity, and practised horse-chaunting, purse-cutting, palmistry, shop-lifting, and ringing the changes, wherefore some were taken and slain. They bore letters of protection from the Emperor Sigismund (procured probably in 1417 at Lindau on Lake Constance), and, after 1422, from Pope Martin V.; and they professed sometimes to be engaged in a seven years' pilgrimage, imposed by their bishops as a penance for apostasy from the Christian faith, sometimes to have been driven out of 'Little Egypt' by the Saracens for refusing to apostatise. Yet another story was told by the *tented* 'Cingari or Cigäwnär,' who appeared at Ratisbon in 1424–26, that their exile was meant 'for a sign or memorial of the flight of our Lord into Egypt.' These, whose woiwode Ladislaus also bore letters (1423) from Sigismund, were natives of Hungary; the others came seemingly from the Balkan peninsula, pioneers of vast hordes behind, who in 1438 began to pour over Germany, Italy, and France, by thousands instead of hundreds, and headed this time by King Zindl. Spain they reached in 1447, Poland and Russia about 1501, Sweden by 1512, England by 1514, and Scotland by 1505, or very possibly fifty-six years earlier, for an act of 1449 refers to 'overliers and masterful beggars' as going about the country with 'horses, hunds, and other goods.'

For western Europe, then, the year 1417 does mark an era in Gypsy history; but how long before that date there had been Gypsies in south-eastern Europe remains a mystery. We recognise them dimly in Crete in 1322 as dwellers in 'little, oblong, black, low tents, like those of the Arabs,' and in caves; at Constantinople about 1050 as 'descendants of the race of Simon Magus, *Atsinkan* by name, sorcerers and famous rogues;' and there, too, in 810 as *Athinganoi*, magicians, soothsayers, and serpent-charmers. Beyond any shadow of doubt, we find them prior to 1346 on Corfu; about 1378 at Nauplion, in the Peloponnesus, receiving a renewal of former privileges; and prior to 1370 in Wallachia, whose woiwode then granted forty tents of *Atsiganï* to the monastery of Voditza i.e. the Roumanian Gypsies were already serfs, and serfs they continued till 1856. Then, in a free metrical paraphrase of Genesis, made in German about or before the year 1122 by an Austrian monk, and cited by Freytag in *Bilder aus der deutschen Vergangenheit* (ii. 226, 1859), the following passage occurs: 'So she (Hagar) had this child, they named him Ishmael. From him are descended the Ishmaelitish folk. They journey far through the world. We call them *chaltsmide* ('workers in cold metal'). Out upon their life and their manners! For whatever they have to sell is never without a defect; whenever he (*sic*) buys anything, good or bad, he always wants something in; he never abates on what he sells himself. They have neither house nor country; every place is the same to them. They roam about the land, and abuse the people by their knaveries. It is thus they deceive folk, robbing no one openly.' That Gypsies were meant here, likely as it seems at first sight, is rendered doubly likely by the fact that the names *Agarenes* and *Agarene* are expressly applied to Gypsies by Lusignan and Fritschius in 1580 and 1664, and that in German and Danish thieves' slang *Gischmedim* and *Smadem* (Ish-

machites are terms for Gypsies at the present date. Finally, the *komodromoi* ('village-roamers') of Greek writers were probably Gypsies. The term is a vague one, but no vaguer than *landloper*, which does in Dutch stand for 'Gypsy. And the *kamarinarioi*, we find, were both copper and gold smiths, roaming about the country, and using bellows made of skins, like those of Hur's Naupliote Gypsies in 1497. The verb *kamadrevein* occurs in Pollux, who flourished about 183 A.D.; and Theophanes Isaurus (758–818 A.D.) speaks under the date 514 A.D. of a *kamadrenos* from Italy. A *kamadromes* figures, moreover, in a Greek apocryphal gospel of unascertained date as helping to crucify Christ, which at once recalls the current Montenegrin legend that the founder of the Gypsy race was accursed for having forged the nails for the crucifixion.* Thus, on the one hand, it is certain that in Wallachia the Gypsies were already reduced to bondage in 1370; it is almost certain that Gypsies were nothing new in Austria in 1122; and it is at least highly probable that more than a thousand years ago there were Gypsies roaming through the Byzantine empire. On the other hand, of the Gypsies' passage of the Bosphorus, and their first arrival in Europe, no record has yet been discovered.

From numbers of scattered notices we may safely infer that the Gypsies in early times possessed every art that they possess to-day, with many besides since lost. Thus, in Scotland in 1530 they 'dansit before the king in Holyrudhouse;' between 1559 and 1628 they yearly 'acted severall plays' at Roslin, where Sir William St Clair, Lord Chief-justice, 'allowed them two towers for their residence, the one called Robin Hood, the other Little John;' in 1726 they cast the church bell at Edzell, in Forfarshire; about 1740 in the Border country they practised engraving on pewter, lead, and copper, as well as rude drawing and painting; and during that century they were famous as fiddlers and pipers, and they worked the small iron-foundry of Little Carron, near St Andrews. In England, again, in 1549 they were capable of counterfeiting the great seal; in Hungary they made bullets and cannon-balls in 1496 and 1565; and there, too, we find them celebrated as musicians as early as the 15th century. A gifted and insinuating race, equal—nay, often superior—to the nations whose lands they roamed, the early Gypsies met with a good reception, as from kaiser and pope on the Continent, so in England from the Earl of Surrey, who about 1519 entertained 'Gypsions' at Tendring Hall, Suffolk; in Scotland from James IV., who in 1505 gave Anthonius Gaginus, 'Earl of Little Egypt,' a letter of commendation to the king of Denmark. In Scotland, too, in 1540, James V. recognised the right of 'oure louit Johnne Faw, lord and erle of Litill Egipt,' to execute justice upon his company and folk, conform to the laws of Egypt. Indeed, it were easy to multiply proofs that Gypsies at a much later date have been held in consideration and regarded with interest. Charles Bosvile, a Gypsy 'king,' who was buried in 1709 at Rossington, Yorkshire, had £200 a year, and 'was a mad spark, mighty fine and brisk, keeping company with a great many gentlemen, knights, and esquires;' 'Queen' Margaret was visited at Norwood in 1750 by the Prince and Princess of Wales, and Lazarus Petulengro at the Liverpool Exhibition of 1886 by Prince Victor of Hohenlohe; whilst the Archduke Josef of Austro-Hungary is a prince among Romany Ryes (or 'Gypsy gentlemen'), as Gypsies designate lovers of their race. Still, liking and pity changed sooner or later to enmity and distrust. For the knaveries of the first immigrants were copied by their successors, and to actual malpractices, charges, more or less baseless, were added—they were kidnappers, cannibals, emissaries of the Turks. The last charge is as old as 1424, the second as 1547, and the first as 1629. Gypsies *were* used as spies by Wallenstein and Frederick the Great, but of cannibalism and child-stealing there is no just ground to suspect them, though for cannibalism forty-five Hungarian Gypsies were racked, beheaded, quartered, or hanged in 1782, for child-stealing forty-seven German Gypsies imprisoned in 1872. The charge in each case proved false. Truly, any wrong-doings of the Gypsies fade into insignificance by the side of the wrongs that were done them. In Germany so lately as the first half of the 18th century, they were hunted down like wild beasts; in one Rhenish principality, says Freytag, the record of a day's 'bag' includes, among other game, 'a Gypsy woman with her sucking-child.' England and Scotland were comparatively merciful, yet at Durham in 1592 'Simson, Arington, Fetherstone, Fenwicke, and Lanckaster were hanged for being Egyptians;' at Banff in 1701 three young Egyptian rogues were sentenced to have 'their ears cropt, be publicklie scourged through the toune, burnt upon the cheek by the executioner, and banished the shyre for ever under the paine of death.' Such are two samples of the cases whose records have come down to us, few probably in proportion to the cases whose records are lost; anyhow, these show that in England and Scotland fully four-score men and women were hanged or drowned between 1577 and 1701 for the offence of being what Nature had made them. The penal laws passed against the race between 1530 and 1596 were repealed in 1784; but even in 1819 it was carried unanimously at the Norfolk Quarter Sessions 'that all persons wandering in the habit or form of Egyptians are punishable by imprisonment and whipping.' One important factor in the geographical distribution of the Gypsies has been deportation—from England to France and Norway (1544); from Scotland to Barbadoes and the American plantations (1665, 1699, 1715, &c.); from Portugal to Africa till 1685, and thereafter to Brazil; from Spain to Louisiana (some time prior to 1800); and from the Basque country *en masse* to Africa (1802).

At Tobolsk in 1721 Bell of Antermony heard of sixty Tsigans, journeying from Poland to China; in 1851 a hundred Hungarian Gypsies passed through Frankfort *en route* for Algeria; since 1866 large bands of *Calderari*, or Gypsy smiths from south-eastern Europe, have made the round of the Continent, visiting Norway, England, even Corsica; in 1879 fez-wearing Gypsies were camping in Sweden; and in 1886 ninety-nine 'Greek' Gypsies were stopped at Liverpool on their way from Corfu to the United States. Thus the nomad instinct survives, and with it a marvellous faculty for picking up foreign languages—a Hungarian Gypsy will speak even Basque like a native. British Gypsies, however, hardly ever visit the Continent; and almost everywhere there are sedentary as well as nomadic Gypsies, though in what proportion it were hard to guess. Sometimes they go into houses only for the winter, but some-

* [illegible] Gypsy, when the three nails would be an easily intelligible pro[illegible]

times the house or cave (not tent or caravan) is their permanent abode. Nay, it is curious that, though there certainly were Gypsy tent-dwellers in Wallachia in 1370, at Ratisbon in 1424, as there are to-day in Persia and America and in all intermediate lands, still, as a rule, the early chroniclers are silent as to Gypsy tents; and the word for 'tent' differs in almost every Rómani dialect, indeed is oftenest a borrowed term.

There are few trades that Gypsies have not somewhere or at some time turned their hands to. In England the writer has known them to follow the callings of clergyman, billiard-marker, Salvationist, betting-man, quack-doctor, chimney-sweep, gun-maker, pugilist, actor, carpenter, cabman, &c., as well as of hawker, knife-grinder, showman, and the like. But everywhere the men follow the three specifically Gypsy callings of horse-dealers (slave-dealers in Brazil, too, formerly), musicians, and workers in metal; everywhere the women are adepts at fortune-telling. Their musical talent has rendered them famous as harpists in Wales, as singers in Moscow, as violinists in Hungary; and from Hungary since 1878 their fame has extended to Paris, London, Liverpool, Edinburgh. There are no such players of the *czardas;* still Liszt's theory that Hungary owes its national music to the Gypsies has been impugned by competent authorities. What then of the paradoxical claim, put forward by M. Bataillard, that Europe —at anyrate northern and western Europe—is indebted to prehistoric Gypsies for its knowledge of metallurgy—i.e. for everything that makes life livable? If we examine this claim, the paradox sensibly diminishes. On the one hand, Sir John Lubbock, without a thought of the Gypsies, had in 1865 been led to the independent conclusion that the art of making bronze was introduced into Europe from the East by a small-handed race like the Egyptians or the Hindus, a nomad race too, who practised the self-same methods in different lands, and who, whether acquainted or not with iron, were exclusively workers in bronze. What race this was he leaves an unsolved problem, except that it certainly was not the Phœnicians. On the other hand, the Gypsies of south-eastern Europe and Asia Minor enjoy a practical monopoly of metal-working. So exclusively is the smith's a Gypsy (and therefore a degrading) craft in Montenegro that, when in 1872 the government established an arsenal, no natives could be got to fill its well-paid posts. In 1880 Mr Hyde Clarke wrote in a letter that 'over more than one sanják of the Aidin viceroyalty the Gypsies have still a monopoly of ironworking, the *naalband*, or shoeing-smith, being no smith in our sense at all. He is supplied with shoes of various sizes by the Gypsies, and only hammers them on.' In 1856 Mr Gardner, consul at Jassy in Moldavia, described the Gypsies as 'the blacksmiths and locksmiths of the country;' in Transylvania, says Boner (1865), 'Gypsies are the best farriers, and as blacksmiths generally they excel. All the ironwork of a village is done by them.' Add to this, and much more of the sort might be quoted, the fact that very many of the early notices of Gypsies, some of which we have cited, refer to their skill in metallurgy. Next, put two and two together, though many important links in the chain of reasoning are necessarily omitted here for want of space. Suppose that there were prehistoric Gypsies in Europe (and history knows nought of their arrival), that they were nomad smiths, like the *kómodromoi* of the 7th century A.D., the 'Ishmaelites' of the 12th century, and the Hungarian *Calderari* who visited Norway in 1874; that they were workers in bronze, to the exclusion of iron, like the Gypsy 'Zlotars' to-day in eastern Gallicia (bell-founders these, like the Scottish tinklers of 1726, and goldsmiths, too, like the *kómodromoi*)—supposing all this, we say, then have we not possibly identified the unknown race, small-handed like the Gypsies, and, like the Gypsies immigrants from the East? An objection, raised by the writer in 1878 to Bataillard's theory, is that in every Gypsy dialect of Europe nearly all the metallurgical terms seem to be directly borrowed from the Greek: *pétalo*, 'horseshoe' (*pétalon*); *kalai*, 'tin' (*kalaion*); *kharkoma*, 'copper' (*chalkoma*); *kakkavi*, 'kettle' (*kakkabí*); *mulav*, 'lead' (*mólybdos*); *rin*, 'file' (*rinē*); and half a dozen more. This looked like an insuperable objection; for how, unless the Gypsies had adopted the farrier's craft since their arrival in a Greek-speaking country, should their word for 'a horse' be Indian, for 'a horseshoe' Greek? But, Bataillard contends, the converse may be the case, the Greeks may have borrowed their terms from Rómani. Certainly, the occurrence of *pedol* in Welsh (12th century, *pedhaul*), for 'horseshoe,' looks like more than a mere coincidence; and *gh'ala*, the word for 'tin' with Asiatic Gypsies, seems to forbid our deriving *kalái* from *kalaion*. Anyhow, Bataillard's theory is gaining favour with foreign archæologists, among whom MM. Mortillet, Chantre, and Burnouf had arrived *independently* at similar conclusions.

The counter-theories as to the origin of the Gypsies need not detain us long. There is the Tamerlane theory of Grellmann (1783), according to which the Gypsies first reached Europe in 1417 —a theory disproved by firmly-established facts. There is the Behram Gur theory of Pott and Bataillard (who since relinquished it), developed in 1844–49, and adopted by Newbold, Sir Henry Rawlinson, De Goeje, Sir Richard Burton, and an *Edinburgh* Reviewer (July 1878). According to this theory, about 420 A.D., Behram Gur imported 12,000 Jat minstrels from India to Persia, and their descendants, gradually wandering westward, entered Europe in 1025 or as late as the beginning of the 14th century. Plausible, and it may be containing a modicum of truth, this theory fails as a whole in view of the marked unlikeness of Játaki, the language of the Jats, and Rómani, the language of the Gypsies. Lastly, attempts have been made, on the ground for the most part of a similar habit of life, to identify the Gypsies with various Indian vagrants—e.g. by Richardson with the Nāts (1803), by R. Mitra with the Bediyás (1870), and by Leland and Grierson with the Doms (1873–88). Even if successful, such identification would prove little more than that India, like Egypt, has its Gypsy tribes—a fact in itself extremely probable, but so far lacking linguistic corroboration.

Language.—What their religion has been to the Jews, that their language is to the Gypsies—a bond of universal brotherhood. For Gypsies everywhere speak the self-same *Romani chiv* ('Gypsy tongue'). Their words for 'water' and 'knife' are in Persia *páni, cheri* (1823); in Siberia, *panji, tschuri* (1878); in Armenia, *pani, churi* (1864); in Egypt, *páni, chúri* (1856); in Norway, *pani, tjuri* (1858); in England, *pani, churi* (1830); in Brazil, *panin, churin* (1886)—where spelling and dates are those of the works whence these words have been taken. But over and above their identity—and there are hundreds more like them in every Gypsy dialect—they are identical with the Hindustani *pani* and *churi*, familiar to all Anglo-Indians. To cite but a few more instances, 'nose,' 'hair,' 'eye,' 'ear' are in Turkish Rómani *nal, bal, yak, kann*; in Hindustani, *nak, bal, akh, kan*; whilst 'Go, see who knocks at the door' in the one language is *Já, dik kon chalarela o cudar*, and in the other *Ja, dekh kon chalaya dear ko*. This discovery was not made

till long after specimens of the Gypsy language had begun to be published by Andrew Boorde (q.v.) in 1547, whose twenty-six words, taken down seemingly in an English alehouse, were intended to illustrate the language of Egypt; by Bonaventura Vulcanius (1597), whose vocabulary of seventy-one words, collected probably in Belgium, fills up some blank pages in a work on the Goths; and by Ludolphus (1691), whose thirty-eight words are embedded in a history of Ethiopia. First in 1782 Rudiger in Germany, followed next year by Grellmann, and in England (independently) by Marsden, observed the resemblance of Romani to Hindustani; and Grellmann straightway leaped to the conclusion that the Gypsies who showed themselves in western Europe in 1417 had newly come also to south-eastern Europe, and were a low-caste Indian tribe expelled from their native country about 1409 by Tamerlane. In 1783 the older languages of India were a sealed book to Europeans, and Grellmann's opinion found almost unanimous approval for upwards of sixty years; but thanks to the linguistic labours of Pott, Ascoli, and Miklosich, combined with the historical researches of Batailland, the question has now assumed a new aspect. For while on the one hand it has been proved that Europe had its Gypsies long before 1417, so on the other Romani has been shown to be a sister, not a daughter—and it may be an elder sister—of the seven principal New Indian dialects. Not a few of its forms are more primitive than theirs, or even than those of Pali and the Prakrits—e.g. the Turkish Rómani *vast*, 'hand' (Sansk. *hasta*; Pali, *hattha*), and *vusht*, 'lip' (Sansk. *ostha*; Pali, *ottha*). Miklosich, however, has pointed out that many of these seemingly archaic forms in Rómani may be matched from the less-known dialects of India, especially north-west India—that we find, for example, in Dardu both *hust* and *usht*.

In the Rómani vocabulary (five thousand words rich perhaps), besides the Indian elements that constitute its basis, there is also a largish percentage of borrowed words—Persian, Armenian, Slavonic, Roumanian, Magyar, &c. Thus, the English dialect has *ambrol*, 'pear' (Pers. *amrud*); *grasnu*, 'mare' (Arm. *yrast*, 'beast of burden'); *paramasin*, 'scandal' (Mod. Gr. *paramútha*, 'story'); *kalecas*, 'stockings' (Slav. *chulcra*); *cari*, 'any' (Roum. *vare*); and *stiffi-pen*, 'sister-in-law' (Ger. *stief-*). These words and the like are a record of the route by which the English Gypsies arrived in England; and as the fifty Greek and the thirty Slavonic words outnumber all the other borrowed words put together, it follows that the Gypsies tarried longest in Greek- and Slavonic-speaking lands. Again, *drom*, *dromi*, or *drom* (Gr. *dromos*) is the Rómani word for 'road' not only in England, but in Turkey, Roumania, Hungary, Bohemia, Poland, Lithuania, Russia, Scandinavia, Germany, Italy, Spain, and Brazil; and the like holds more or less good of the Gypsy words for 'Sunday,' 'chair,' 'hat,' 'anger,' 'bone,' 'soup,' 'pawn,' &c. from the Greek; for 'pease,' 'beer,' 'inn,' 'cat,' 'cloak,' &c. from the Slavonic. This is important as indicating that the modern Gypsies are descended not from successive waves of Oriental immigration, but all from the self-same European-Gypsy stock, whenever that stock may have first been transplanted to Europe. It conclusively negatives a theory like Kounavine's, that the Italian, Spanish, Basque, and French Gypsies arrived at their present habitats by way of Africa, and the Scandinavian Gypsies by way of the Ural Mountains. Still more important is the question of the presence or the absence of Arabic words in European Rómani. According to De Goeje (1875) there are ten such words; according to Miklosich (1878)—and rightly as it seems—there are none. Neither, however, of the two scholars has perceived the possible importance of the presence or the absence (especially the absence) of Arabic elements. Rómani undoubtedly contains Persian words; would it not have certainly contained also Arabic words if the ancestors of our modern European Gypsies had sojourned in Persia, or even passed through Persia, at a date later than the Arab conquest of Persia? If Miklosich is right in his contention that there are no Arabic words in European Rómani, it follows almost inevitably that the Gypsies must have passed through Persia on their way to Europe at some date prior to the middle of the 7th century A.D. In this connection it should be pointed out that the dialect of the Gypsies of Asia Minor differs far more, alike in grammar and in vocabulary, from that of the Gypsies of Turkey than does the latter from that of their brethren in Wales.

The Gypsies of Montenegro are said to have completely lost their language; elsewhere Rómani has suffered more in grammar than in vocabulary. In Spain, in Brazil, in Scotland, and in Norway its genuine inflections have been wholly or almost wholly superseded by those of Spanish, Portuguese, English, and Norwegian. In England this process is still going on, affording an unquestionable instance of 'mixed grammar,' such as Max Müller has pronounced an impossibility. There is every variety of shade, from almost absolute purity to as almost absolute corruption. Thus, a Welsh Gypsy writes in a letter, *Dava ma temen borro parichyáva* for *tomorro camlo drom* ('Give I you great thanks *for* your loving way'); and an English Gypsy, *Mandy kek gin so* to *pen* ('Me not know what *to* say'), where the pure Rómani would run, *Kek me jaanva me so te penar*. No Gypsy dialects have been better preserved than those of Turkey at one end of Europe, and of Wales at the other end; from a comparison of these it is easy to see how little they can have altered since the ancestors of those who now speak them parted company five centuries ago. Thus, the twenty-one forms in Turkish Rómani of the third personal pronoun (masc., fem., and plur.), with two exceptions, reappear almost or quite unchanged in the Welsh dialect. The plural, for instance, runs in Turkish Rómani, *ol*, 'they;' *len*, 'them;' *léngoro*, 'their;' *léndhe* or *lénghe*, 'to them;' *léndja*, 'with them;' *léndar*, 'from them;' and in Welsh Rómani the corresponding forms, occurring in letters written by a self-educated Gypsy, are *yon*, *lon*, *longo*, *lendy* and *lengey*, *lensa*, and *lenda*. Four of the cases, it will be seen, are formed by suffixing postpositions to the accusative; and this, too, holds good of the nouns. Many of the verbal inflections are almost equally simple, and may be as readily analysed by means of Rómani itself. In the final syllables of *dá-va*, 'I give;' *dé-sa*, 'thou givest;' and *dé-la*, 'he gives,' we recognise the first, second, and third pronouns. From the past participle *dino* and *isóm* or *hom*, 'I am;' *isomas* or *homas*, 'I was,' are formed *diniom*, 'I gave;' and *diniómas*, 'I had given'—formations recalling those of Latin deponents. The future, formed by prefixing *kama* ('will') to the present, as *kamadáva*, 'I will give,' was modelled probably on the Modern Greek *thélo* or *tha*.

So far, our ablest Gypsiologists are divided in opinion as to the probable antiquity of Rómani. On the one hand Ascoli maintains that, 'having retained certain *nexus*, or combinations of consonants, which had almost wholly disappeared at the epoch of the oldest known Prakrit texts, this lowly idiom herein surpasses Pali itself in nobility, and more nearly approaches Sanskrit.' Miklosich, on the other hand, contends that 'from the agreement of Rómani in so many important points with the

modern Aryan languages of India, it follows that the emigration cannot have taken place till after the formation of the latter—i.e. till after the Prakrit period, in which the old system of declension was still recognised; since one is hardly inclined to assume that Rómani, severed from its most nearly-related idioms, developed itself in the selfsame manner as they.' In his *Comparative Grammar of the Modern Aryan Languages of India* (3 vols. 1872–79) Mr Beames arrives at a similar conclusion, that 'the language of the Gypsies is purely Aryan in its structure, and Modern Aryan too, being in many respects quite as far removed from the old synthetical system as any of the seven languages now under discussion.'

Names.—Alike in Turkey and England, in Finland and Italy, the Gypsy calls himself *Rom* ('man' or 'husband'), from which come *Rómni* ('female Gypsy,' 'woman' or 'wife') and the adjective *Rómano* ('Gypsy'). In Asia Minor the form is *lom*, and in Syria *doum*, which comes very near the Sanskrit *doma* and modern Indian *dom*, 'a low-caste musician. 'Husband' is clearly a secondary meaning of *Rom*, and 'man' the primary; so that one is almost tempted to connect *Rom* with the ancient Egyptian *rôme*, 'man' (Rawlinson's *Herodotus*, ii. 225), and to believe that there really is something in the alleged Egyptian origin of the Gypsies. That belief was assuredly current in south-east Europe prior to their westward migration, and is current to-day from Armenia to America, having been stereotyped in such names as the modern Greek *Gyphtoi*, the Albanian *Jevk*, the Turkish *Farâwni* and Magyar *Pharao népe* ('Pharaoh's folk'), the English *Gypsy*, and the Spanish *Gitano*. Another very widespread name is the Syrian *Jingânih*, Modern Greek *Atsinganoi*, Turkish *Tchinghiané*, Magyar *Tzigany*, German *Zigeuner*, Italian *Zingaro*, &c., perhaps identical with the Persian *zingar*, 'a saddler.' We can merely glance at the infinite variety of names applied to the Gypsies in different ages and different localities—e.g. *Heiden* ('heathen'), *Saraceni*, *Nubiani*, *Uxii*, *Cilices*, &c. by early writers, and the Persian *Karâchi* ('swarthy'), the Modern Greek *Katzibeloi*, the Cypriote *Kilindjiridès*, the French *Bohémiens*, and the Scandinavian *Tatere* ('Tartars'). Only, if under these manifold and frequently misleading names we can safely recognise Gypsies, it is at least just possible that we should also recognise them in the *Dynamitters* (traders from foreign parts who sold brazen pots at Winchester fair in 1349), in the *Bemische* ('foreigners' at Würzburg about 1388; Gypsies incontestably at Frankfort in 1495); in the tent-dwelling refugees from Hungary and Lorraine, who are said to have discovered the Stourbridge fireclay about 1555; or even in the Kenites, nomad tented tinkers and blacksmiths in ancient Palestine (*cf.* Sayce and Neubauer in the *Academy*, Nov.–Dec. 1886). In England, common Gypsy surnames are Boswell, Buckland, Cooper, Gray, Herne, Lee, Lovell, Smith (*Petulengro*), and Stanley—assumed, some at least, probably from former patrons of the race. Among their 'Christian' names are Mantis, Perun, Plato, and Pyramus; Delarîfa, Meralini, Memberênci, Perpénia, and Sinaminti.

Songs and Folk Tales. *Chin*, Rómani for 'write,' means literally 'cut,' so points back to a dim antiquity; still, the Gypsies have neither alphabet nor literature. Many Rómani songs, however, have been taken down in Spain, Hungary, Roumania, and elsewhere—ballads, love- and dance-songs, and threnodies. The last, collected in Transylvania by Wlislocki, are instinct with pathos and poetry; but the rest, rude in rhyme and in rhythm, as a rule have only a linguistic value. The famous 'Pharaoh lay' is known to us only through a very corrupt fragment. The case is otherwise with Gypsy folk-tales, of which nearly 200 have been collected since 1862 in Turkey, Roumania, Austro-Hungary, Wales, &c. A meagre store, yet sufficient to enable us to arrive at certain definite conclusions. First, in different collections we meet with variants of one and the same story—e.g. three of 'The Valiant Little Tailor,' and three of 'The Master Thief.' Secondly, many (perhaps most) of the Gypsy stories are identical with, though not seldom superior to, stories current amongst non-Gypsy races. Thirdly, there are certain episodes in Gypsy stories, and certain whole Gypsy stories, for which diligent research has failed to produce any parallel. Fourthly, a number of non-Gypsy stories present strong internal evidence of the probability of their Gypsy origin. Now, as early as 1856 the Gypsies were termed the 'rhapsodists of Moldo-Wallachia;' in Turkey Gypsies are professional story-tellers; their stories there are proved to be 'very old' by their retention of otherwise forgotten Rómani words; in the Scottish Highlands a tented tinker was one of Campbell's four principal sources; and finally, according to Benfey, Ralston, Cosquin, Clouston, and other folklorists, most of the popular stories of Europe are traceable to Indian sources (see FOLKLORE). But how? by what channels?—one channel, perhaps, was the Gypsies.

Religion.—Of the Gypsies' religion not much need be said, as they do not possess one. They probably had one at starting; but, if so, they lost it by the way. In spite of frequent statements to the contrary, Rómani has words for God, devil, soul, heaven, cross; but *trúshul*, 'cross,' originally stood for Siva's trident. So, too, their folklore enshrines many strange survivals of dead heathenry—of tree and serpent worship, of phallicism, tabu, and the vampire superstition. But everywhere Gypsies profess the faith of the land of their adoption—Mohammedan, Orthodox, Catholic, Protestant. They bring their children to baptism, and are scrupulous in the matter of Christian sepulture. At Steinbach in 1445 the 'high-born Duke Panuel' was buried beneath a scutcheoned monument; at Dayton, Ohio, in 1878, 'Queen' Margaret Stanley was borne with regal honours to the grave; and scores of similar cases could be cited in England, where at Malmesbury in 1657 'John Buccle, a gypsie, was buried in King Athelstone's chapel,' and at Steeple Barton in 1794 'Peter Buckland, a great man among the Gypsies, said to be very wealthy,' was interred in the chancel. Otherwise, unless for marriages, nor always then, the Gypsies are not great church-goers.

Character.—There are Gypsies and Gypsies. The better sort are quick-witted, courteous, likeable, trustworthy when trusted, and lavishly generous with the one hand, though the other may itch for a bargain. Untrammelled by prejudices, and vexed by no lofty ambition, they have picked up a sort of peripatetic philosophy, so lead a pleasant, cuckoo-like existence, and make the best of this life—for a next they have small concern. As to faults, these 'spoilt children of Nature' are boastful, passionate, crafty, superstitious, thriftless, and indolent; they break most of the Decalogue's precepts, but lightly—great criminals are few among them. Still, horse-dealing and palmistry have not proved ennobling vocations. Piety, which is rare with Gypsies, is apt to assume the form of cant; and learning, which is rarer, of conceit. Indeed, the best Gypsy is the Gypsy *au naturel*, the life-long tent-dweller in country lanes; and he, like all *ferœ naturæ*, is threatened with extinction. Gypsies' virtues are largely their own, an outcome of open-air life; their vices are ascribable to centuries of oppression, which have left them a singular compound of deep-seated gloom and quicksilver light-heartedness, have made them suspicious and hostile

towards all the rest of mankind. 'There's nothing worse,' says the Gypsy, 'than nasty gaujos,' than all, that is, who have not enjoyed the privilege of Gypsy birth. For of that he is genuinely proud; he is honestly grateful that *he* 'hasn't got to live in none of your poverty houses.' Gypsy celebrities, outside the realm of music, have been few. John Bunyan has been claimed as one, but on slender grounds; so have Masaniello and the painter Antonio Solario (1382–1455), nicknamed 'Lo Zingaro.' Anyhow there is Jem Mace, the champion pugilist; and Mrs Carlyle was proud of her Baillie ancestry.

Physique.—Early writers all speak of the Gypsies as hideous, but such language is like early travellers' descriptions of Alpine scenery. For the race is a comely one: its most marked characteristics the tawny olive skin, the dark lustrous eye, the dazzling teeth, the black or dark-brown hair (often frizzled and somewhat coarse), the thoughtful brow, and the lithe sinewy form, with finely-made hands and feet, and arms short in comparison to the legs. The skull is mesocephalic.

Bibliography.—There are more than 300 books, pamphlets &c. on the Gypsies, but one and all might have seemed almost valueless beside the 'immense collections' of Michael Ivanovitch Kounavine (1820–81). A Russian by birth, by profession a medical man, he lived, we are told, during 1841–76 among the Gypsies of Germany, Austria, southern France, Italy, England, Spain, Turkey, northern Africa, Asia Minor, central Asia, Hindustan, and Russia, and, with much else, collected 385 tales, traditions, and ritual songs, cushtas; a wealth of mythological and legendary lore. Unfortunately those collections have disappeared, and we know them only through an abstract formed before the collector's death by his friend, Dr A. Elysseef, member of the St Petersburg Geographical Society, and translated from Russian through French for the *Gypsy Lore Journal* (1890). Indian Gypsies have been treated by MacRitchie (1886); Persian by Sir W. Ouseley (1823) and Newbold (1850); Syrian by Pott (German, 1846), Seetzen (Ger. 1854), Newbold (1856), and Everett (1890); Anatolian by Pasparti (French, 1870) and Elysseef (1889); Armenian and Siberian by Miklosich (Ger. 1878); Egyptian by Newbold (1850), Von Kremer (Ger. 1852), and Leland (1873–82); Central African by Felkin (1889); Algerian by Batellard (Fr. 1874); Turkish by Pasparti (Fr. 1870) and Colocci (Ital. 1889); Roumanian by Kogalnitschan or Cogalnitceanu (Fr. 1837) and Vaillant (Fr. 1868); Montenegrin by Bogisic (Ger. 1874); Servian by Miklosich (Ger. 1876); Bosnian by Kopernicki (1890); Hungarian by Bright (q.v., 1818) and the Arendalske Josef Hung. 1888); Transylvanian by Wlislocki (Ger. 1880–89); Bohemian by Puchmayer (Ger. 1821) and Jecna (Ger. 1886); Slovak by Kalina (Fr. 1882) and Von Sowa (Ger. 1887–90); Polish by Danilowicz (Pol. 1824) and Czicki (Pol. 1845); Crimean by Koppen (Ger. 1874; Eng. 1890); Russian by Böhtlingk (Ger. 1853) and Miklosich (Ger. 1872–78); Lithuanian by Narbutt (Pol. 1830) and Dowojno-Sylwestrowicz (1890); Norwegian by Smidt (Norw. 1850–65); Danish by Dyrlund (Dan. 1872); German by Liebich (Ger. 1863); Dutch by Dirks (Dutch, 1850); English and Welsh by Bryant (1784), Hoyland (1816), Harriot (1830), Crabb (1831), Roberts (1836), Borrow (q.v. 1841–74), Leland (1873–82), Smart and Crofton (1863–88), and Groome (1880); Scottish by Baird (1839–62), Simson (1865), MacRitchie (1884–94); Basque by Michel (Fr. 1857), Boudrimont (Fr. 1862), and Wentworth Webster (1888); Italian by Ascoli (Ger. 1865) and Colocci (Ital. 1889); Catalonian by MacRitchie (1888); Spanish by Borrow (1841), Campuzano (Span. 1851), and Mayo (Span. 1870); Brazilian by Melo Moraes (Port. 1885–86); and North American by Simson (1865) and Leland (1882). Hereto should be added, for music, Liszt (Fr. 1859), Leland (1882), and Thewrewk de Ponor (1889); for folklore and folktales, Leland's *Gypsy Sorcery* (1891) and eight works cited by Groome in the *National Review* for July 1888; for costume, Crofton (1876); for metallurgy, Andree (1884); for craniology and physique, Kopernicki (Ger. 1872), Hovelacque (Fr. 1874), and Weisbach (Ger. 1889); for history, Grellmann (Ger. 1783, Eng. trans. by Raper, 1787, Sprengler (Lat. 1839), Hopf (Ger. 1870), Crofton (1888), and, especially, Bataillard (1844–90), and for the language as a whole, Pott (q.v., Ger. 1844–45), Ascoli (Ger. 1865), and Miklosich (q.v., 1872–80). Of these works the fullest of several bibliographies is that furnished by Colocci in *Gli Zingari* (Turin, 1889). Painters to whom the Gypsies have furnished subjects have been Caravaggio, Callot, Morland, Phillip, and Burgess; novelists, poets, playwrights, and composers Cervantes, Scott, Victor Hugo, George Meredith, Le Fanu, Theodore Watts, Matthew Arnold, George Eliot, Peschken, Kruszewski, Brachvogel, Richepin, Balfe, Verdi, Brahms, Bizet, &c. (see Grosche, *Die Zigeuner als Typus in Dichtung und Kunst*, 1879). Finally, a vast mass of material is to be found in the quarterly *Journal* (Edin., Constable) of the cosmopolitan Gypsy Lore Society, which was founded in 1888, and survived until 1892.

Gypsum is a valuable mineral of a comparatively soft nature. Chemically it is a hydrated sulphate of lime, $CaSO_4 + 2H_2O$. Its specific gravity is 2·31, and its hardness is from 1·5 to 2 of the mineral scale. The massive marble-like variety, which is usually white or delicately tinted and translucent, is called Alabaster (q.v.); when transparent and crystallised it is known as Selenite (q.v.); and when fibrous and with a pearly opalescence it is termed satin spar.

Gypsum occurs in various geological formations, and has a wide geographical distribution. Extensive beds of the common variety are generally made up of irregular, concretionary, nodular masses. In the New Red formation near Derby, at Carlisle, and in some parts of Nottinghamshire, as well as in the Tertiary beds of the suburbs of Paris, it is largely worked for the preparation of plaster of Paris. Productive beds of it are found in numerous localities in the United States, principally in Ohio and Michigan; in New Brunswick, Nova Scotia, and Ontario; and in the Punjab. Gypsum is very frequently associated with rock-salt. See ANHYDRITE.

Gypsum contains 21 per cent. of water, which can be driven off by heat. It is burned in kilns at or a little below a temperature of 250° F., and afterwards ground to a fine powder, which is called *plaster of Paris*. This recombines with water, evolves heat, and almost immediately solidifies or *sets*. It is this property which makes it so serviceable for many purposes in the industrial arts. If in the burning of gypsum the temperature is raised as high or higher than 480° F. it loses the power of rehydrating, and is then said to be *dead burnt*, in which state it will not set when mixed with water. Like gypsum, plaster of Paris is soluble to the extent of rather more than 2 parts in 1000 parts of water at ordinary temperatures, its point of maximum solubility being 95° F. It is therefore unsuited for external work, except in dry climates such as that of Persia. For making casts the plaster of Paris is made up with water to a consistency of thick cream. In this state it is poured into a mould, which is usually also made of the same material, and left to solidify. Some oil, such as olive, is brushed over the mould to form a *parting* between it and the cast. Plaster of Paris is most extensively used for taking casts of sculpture and architectural details, as well as for casts of small objects such as coins, medals, and engraved gems. For pottery moulds it is also largely employed, and it is used to take a first copy from the modelled clay in the production of metal patterns. Large quantities of it are consumed for the mouldings of the internal plasterwork of houses, and for cornice and other ornaments. For hardened plaster of Paris, such as Keene's cement, see CEMENTS; and for the agricultural applications of gypsum, see MANURES. Gypsum is one of the substances which renders

water hard, and such water is useful in the brewing of some kinds of beer. *Pearl hardening*, used as a filling in the manufacture of some kinds of paper, is an artificial sulphate of lime, precipitated by sulphuric acid from chloride of calcium. *Fictile Ivory* is plaster of Paris which has been made to absorb beeswax, spermaceti, and stearic acid, in their melted state.—The average annual production of gypsum in Great Britain is nearly 120,000 tons, value about £48,000. In 1888 the production of the United States was about 96,000 tons; of Nova Scotia, 126,118 tons. For the anhydrous sulphate of lime, see ANHYDRITE.

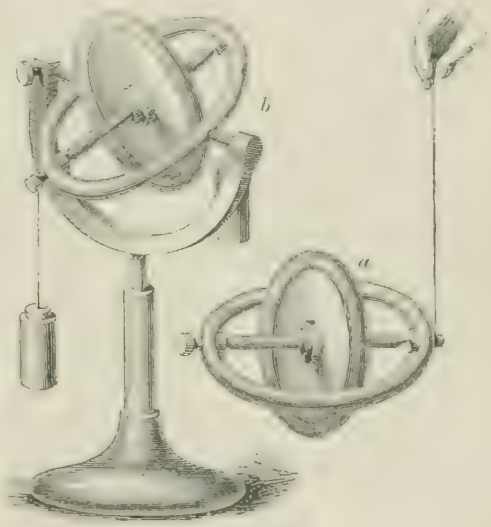
Gypsy-wort (*Lycopus europæus*), sometimes also called Water Horehound, is a perennial plant belonging to the natural order Labiatæ. It is a tall erect branching plant, slightly hairy, with a creeping root-stock. It is common in moist places in Britain, the Continent, Russian and central Asia, and North America; and is regarded as a febrifuge and astringent. It dyes black, and gives a permanent colour to wool, linen, and silk, and as long ago as 1578 the Gypsies were fabled to stain their skin with it. The Bugle-weed of North America (*L. virginicus*) has more powerfully astringent properties.

Gyrfalcon. See FALCON.

Gyroscope (Greek) is the name given to an instrument for the exhibition of various properties of rotation and the composition of rotations. It differs from a top in having both ends of its axis supported. The invention is probably French or German, and in some of its forms it dates from about the end of the 18th century.

If a mass be set in rotation about its principal axis of inertia of greatest or least moment, it will continue to revolve about it; and, unless extraneous force be applied, the direction of the axis will remain unchanged. Such, for instance, would be the case with the earth, were it not for the disturbances (see NUTATION and PRECESSION) produced by the sun and moon: the direction of the axis would remain fixed in space. It is for this very reason that modern artillery is rifled. If, then, a mass of metal, as, for instance, a circular disc, loaded at the rim, and revolving in its own plane, be made to rotate rapidly about its axis of greatest moment of inertia, and if it be freely supported (in gimbals, like the box of a compass), the direction of its axis will be the same so long as the rotation lasts. It will therefore constantly point to the same star, and may, of course, be employed to show that the apparent rotation of the stars about the earth is due to a real rotation of the earth itself in the opposite direction. This application was made by Foucault shortly after his celebrated Pendulum (q.v.) experiment, as it had been many years before (March 1836) by Dr Sang (see the *Trans. of the R. Scot. Soc. of Arts*). It is, in practice, by no means so perfect a mode of proving the earth's rotation as the Foucault pendulum; but this arises solely from unavoidable defects of workmanship and materials. Professor Piazzi Smyth has applied this property of the gyroscope to the improvement of our means of making astronomical observations at sea. A telescope, mounted on the same support as the ends of the axis of the gyroscope, will, of course, be almost unaltered in position by the rolling or pitching of a vessel; and a steady horizon, for sextant observations of altitude, may be procured by attaching a mirror to the support of the gyroscope, and setting it once for all by means of spirit-levels.

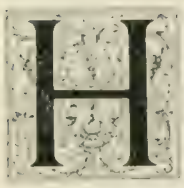
But the most singular phenomena shown by the gyroscope are those depending on the *composition* of rotations (see ROTATION). Any motion whatever of a body which has one point fixed is of the nature of a rotation about an axis passing through that point. Hence, simultaneous rotations about any two or more axes, being a motion of some kind, are equivalent to a rotation about a single axis. The effect, then, of impressing upon the frame in which the axis of the spinning gyroscope is suspended a tendency to rotate about some other axis, is to give the whole instrument a rotation about an intermediate axis; and this will coincide more nearly with that of the gyroscope itself, as the rate of its rotation is greater. The compound motion consists in the rolling of an imaginary cone fixed in the gyroscope upon another fixed in space; the rotation of the axis of a top round the vertical (when it is not 'sleeping' in an upright position), and the precession of the earth's axis, are precisely similar phenomena. Thus, when the gyroscope is spinning, its axis being horizontal, a weight attached to the framework at one end of the axis (fig. *b*) makes the whole rotate about the vertical; attached to the other end, the rotation takes place in the opposite direction. And the framework may be lifted by a string attached near



Gyroscope.

one end of the axis (fig. *a*) without the gyroscope's falling. Its axis still projects horizontally from the string, but it revolves as a whole round the string. Various other singular experiments may be made with this apparatus; and others, even more curious, with the gyrostat of Sir W. Thomson, which is simply a gyroscope enclosed in a rigid case, by which the ends of its axis are supported. When a gyrostat is made the bob of a pendulum under certain conditions, the plane of vibration of the pendulum turns, as in Foucault's celebrated experiment, but in general at a much greater rate.

H



the eighth letter in our alphabet, is derived from the Phœnician letter *cheth*, which was obtained from the Egyptian hieroglyphic symbol which goes by the name of the sieve—see ALPHABET. The Semitic name, which means a 'fence' or 'palisade,' is explained by the form of the letter 𐤇, which resembles a three-barred stile. The sound was that of a strongly marked continuous guttural, produced at the back of the palate, which does not exist in English, but is heard in the Scotch *loch* and the German *lachen*. When the Phœnician alphabet was transmitted to the Greeks the name *cheth* became *eta*. As early as the 7th century B.C. this sign had two values among the Greeks; it normally represented the long *ē*, but was permissively used for the simple aspirate *h*. In the alphabet of Italy it was used exclusively for the aspirate; but in the later alphabet of Greece the two sounds came to be represented by a differentiation of the symbol, the form H being used for the vowel and the mutilated forms ⊢, ʟ, for the aspirate. Hence we see how the symbol H stands for *h* in the Latin alphabet and for *ē* in the Greek.

In Old English *h* was a guttural, or throat-sound, but it gradually softened down to a spirant, and has now become almost a vowel. No letter is more misused, and this misuse is of very ancient date. In Latin MSS. and inscriptions it is sometimes improperly inserted, as in the words *harena*, *harunda*, *hauctoritas*, or improperly omitted, as in *omini*, *abitat*, *onustus*—spellings which prove the uncertainty of the usage. In English as early as the 12th century we find *ard* written for *hard*, and *hold* for *old*. Americans, as a rule, rarely misuse it, and in England an untaught peasant is usually more correct than a self-made man. It has long disappeared from Italian, and is now rapidly vanishing from French. The Spaniards substitute *h* for a Latin *f*, the Spanish *hijo* representing the Latin *filius*, just as the Latin *hordeum* represented the Sabine *fordeum*. Not only *f*, but *c* and *s* are frequently represented by *h*. Thus, *hundred* and *century*, *heartiness* and *cordiality*, *hall* and *cell* are true doublets, while the Latin *canis*, *centum*, and *caput* correspond to the English *hound*, *hundred*, and *head*, and the first syllables of *hexagon* and *heptarchy*, which are derived from the Greek, correspond to the English numerals *six* and *seven*. We get *hemi*-sphere from the Greek and *semi*-circle from the Latin, *hyper*-critical from the Greek and *super*-ficial from the Latin. The Irish have retained *s*, which in Welsh has faded down to *h*, the Welsh *hen*, 'old,' being the Irish *sen* and the Latin *senex*. In English *h* has been lost in the words *it*, *eaf*, *nick*, *ring*, *tear*, *fir*, which were formerly written *hit*, *hlaf*, *hnecca*, *hring*, *taher*, and *feoh*, while in *droht* and *genoh*, now written *draft* and *enough*, it has become *f*, and in the words *huge*, *wharf*, *whelk*, and *whelm* it is intrusive. In *hwit* and *hweol*, and many other words, the decay of the aspirate caused them to be written *white* and *wheel*, and except in the north of England the *h* in these words is hardly heard. In the west and south of England, which are Saxon, the aspirate as a rule is fainter and more liable to be lost than in East Anglia, Yorkshire, and Scotland, where we have the descendants of Angles and Danes.

The correct pronunciation of this difficult letter is one of the most delicate tests of good breeding. The quality of the sound depends partly on that of the following vowel, and its intensity to some extent on the accentuation. The aspiration is stronger in *humble* than in *humility*, in *human* than in *humane*, in *history* than in *historical*, in *hostile* than in *hostility*, but it is the same in *happy* and *happiness*, since the accent rests on the same syllable. It is stronger in *who* than in *when*, in *hole* than in *whole*. In *honour* it is very faint, in *honourable* and *honesty* it is almost inaudible. It is stronger in *host* than in *hospital*, while in *hostler* it has so completely disappeared that the spelling *ostler* has become usual. It is retained in *harbour*, but has been lost in *arbour*. It is retained in *hair* and *hare*, but is evanescent in *heir* and *hour*, though retained in *hereditary* and *horologe*. No general rule can be laid down for the pronunciation; it depends on the usage of good society, which changes from generation to generation. In good French society the aspirate is disappearing; in England and America the reverse is probably the case. The reasons why persons who omit *h* where it should be inserted and commonly insert it where it should be omitted are obscure, but have been referred by Mr Douse in his book on *Grimm's Law* to what he designates as the Principle of Cross Compensation.

In German musical notation the letter H is used to denote B natural, the letter B being applied to our B flat. This anomalous distinction is derived from the ancient notation by letters, before the invention of the stave, in which B natural was written in a square form (B *quadratum*), like a small black letter h, while B flat was written as a Roman b (B *rotundum*). The awkwardness of having two B's led to the introduction of the H, which in small black letter (h) resembles h closely. See 'Accidentals' in Grove's *Dictionary*. In the French and Italian system the same note is denoted by the syllable *Si*. See MUSIC, SCALE, SOLFEGGIO.

Haag, CARL, German painter, born 20th April 1820, at Erlangen, studied at Munich (under Cornelius) and at Rome. In 1847 he settled in England, at the same time abandoning oil for water-colours. His earlier pictures represented scenes from Tyrol and Dalmatia, and from the life of the English royal family in Scotland. His later works have been mostly illustrative of oriental subjects, such as the life of the Bedouin of the desert, the ruins of Baalbek and Palmyra, and similar themes.

Haarlem, a town of Holland, 10 miles W. of Amsterdam, is intersected, like most Dutch towns, with canals and avenues of trees. Of its churches the principal is the Great or St Bavon's, a Late Gothic basilica, built in the 15th century, one of the largest churches in Holland, and specially noted for its lofty tower and its organ (1738), long esteemed the largest and finest ever constructed.

Before the church stands a statue of Laurens Coster (q.v.), to whom his countrymen ascribe the invention of printing. The town-hall, formerly the residence of the Counts of Holland, has portraits by Franz Hals, and a valuable collection of early printed works. The Teyler Institution promotes the study of theology, natural science, and the fine arts. Although Haarlem is no longer celebrated, as it was in the 17th century, for its flourishing trade, it still weaves cotton, casts type, bleaches linen, and carries on an extensive trade in flowers, especially in tulips, hyacinths, and other bulbs. It was a flourishing town as early as the 12th century, when it took an important part in the wars between the Hollanders and West Frisians. At the close of the 15th century it was deprived of its privileges by Albert of Saxony, and it suffered severely during the revolt of the peasantry (1492). During the war of independence it underwent a seven months' siege (1572-73) from the Spaniards, in which the citizens displayed the noblest heroism. The wood of Haarlem is a favourite place for recreation; in it stands the 'pavilion,' which contains the colonial and industrial museums and a collection of modern pictures. Pop. (1876) 34,132; (1894) 58,390.

Haarlem Lake, which is now drained (see POLDER), lay between the towns of Haarlem, Leyden, and Amsterdam, and communicated with the Zuider Zee by the Y. Originally it embraced four small lakes, which, in consequence of several irruptions of the sea, eventually merged into one sheet of water, covering an area of about 45,230 acres. The depth did not exceed 15 feet; the floor of the lake was largely composed of mud and clay, from which the Dutch prepared 'klinkers,' bricks used for purposes of paving. The lake frequently rose during storms to an alarming height, necessitating a large annual outlay in keeping the dams and sluices in repair. In consequence of the damage done to Amsterdam and Leyden by two successive overflows of the lake in 1836, the government seriously addressed itself to the task of draining it (1839–52). This undertaking was effected by digging all round the lake a large canal, into which its waters were pumped by three gigantic engines. By these means the waters were drained off to the Y and Zuider Zee. The enterprise cost £1,080,000, but the sale of the lands reduced this outlay by £780,000. The population increased from 7000 in 1860 to 16,000 in 1895.

Habakkuk (Heb., 'embrace'), one of the twelve minor prophets of the Old Testament. His personal history is unknown. In his book he appears as a prophet of Judah, announcing the divine chastisement which is to come upon his nation at the hands of the Chaldean Nebuchadnezzar. He was the first of the prophets who saw in the great victory of Carchemish (Circesium), in the fourth year of Jehoiakim, the fall of the Egyptian supremacy before the young Babylonian king. His period is thus fixed in the last decade of the 7th century B.C. Both as a poem and as a prophecy his book holds a very high rank among the Old Testament scriptures. His aim was to inspire his nation with trust in Him who is the God of Israel from everlasting, his 'Holy One' (i. 12). After asking God why he had so long suffered his prophet to cry in vain for deliverance from the sight of iniquity and grievance (i. 2–4), he gives a vivid description of the Chaldeans (i. 5 *et seqq.*). Then he betakes himself in spirit to his watch-tower (chap. ii.), and sees that this violent nation shall at last become the scorn of the nations it has spoiled, its idols will be of no avail: 'Jehovah is in his holy temple; let all the earth keep silence before him' (ii. 20). From this prospect he rises to the prophetic height of the third chapter, which is a majestic hymn describing in the most striking images the appearance of the Almighty for judgment, and ending (16–19) with the impression produced by this prophecy on himself, and a beautiful expression of his confidence in God, whatever may befall. The keynote of the whole prophecy is the sentence in ii. 4: 'the just shall live by his faith,' quoted by St Paul in Rom. i. 17, and Gal. iii. 11. The best commentaries on Habakkuk are those of Delitzsch (1843), Hitzig (3d ed. 1863; 4th ed. by Steiner, 1881), Ewald (1867; Eng. trans. in vol. iii. of his *Prophets*, 1878), Kleinert (1869), and Keil (1873).

Habberton, JOHN, author, was born in Brooklyn, New York, 24th February 1842, served through the civil war, and was for some years a clerk, afterwards turning to journalism. His best-known book is *Helen's Babies* (1876), which attained an astonishing popularity both in America and in Europe. He has published also *The Barton Experiment* (1877), *Other People's Children* (1877), *The Worst Boy in Town* (1880), *Who was Paul Grayson?* (1881), a humorous Life of Washington (1883), *One Tramp* (1884), *Brueton's Bayou* (1886), and other works.

Habeas Corpus, in English law, is the formal commencement of several writs, issued by the superior courts, which direct a person who has another in custody to produce the body of the prisoner. Such writs are or have been used in practice for various purposes. Thus, the *habeas corpus ad respondendum* was used to bring up a prisoner to serve him with a writ; and the *habeas corpus ad testificandum* may still be used to bring up a prisoner to give evidence. But the best-known and by far the most important form of the writ is the *habeas corpus ad subjiciendum*, by which the person detaining another in custody is ordered to bring up his prisoner, and to state the reasons for such detention, that the court may judge of their sufficiency. This 'prerogative writ' is one of the chief securities of English liberty. By the law of England, as embodied in the Great Charter, no freeman could be imprisoned except for a crime of which he was found guilty by his peers, or for a civil debt. The effect of this rule of law was that the executive government had no right to imprison an individual on suspicion, or for an indefinite period. Arrest and imprisonment could only be justified by making a definite charge against the prisoner, and by putting him on his trial before a jury without unreasonable delay. A person illegally imprisoned could demand of the Court of King's Bench a writ of *habeas corpus;* and on return being made to the writ, the court might discharge the party, or admit him to bail, or send him back to await his trial, according to the nature of the case. This was the rule of law; but it need hardly be said that in despotic times the courts could not be relied on to protect the subject against illegal imprisonment. In the reign of Charles I. the judges refused to issue a *habeas corpus* in vacation time. They also assumed a discretionary power to grant or refuse the writ; and the government sometimes evaded the law by sending prisoners beyond the sea, to Jersey and other places. These abuses led in 1679 to the enactment of the statute 31 Car. II. chap. 2, commonly known as the Habeas Corpus Act. This act did not, as is often supposed, introduce any new form of process; but it secured to the subject the ancient constitutional remedy of which the weakness of the judges and the bad faith of the government had deprived him. The writ may be sued out by motion in court, or by an application to the Lord Chancellor or one of the judges, supported

by affidavits showing that the person on whose behalf the motion or application is made is illegally detained. The chief rules of the act are as follows. When a person is committed to prison the judge to whom application is made must, unless there has been great delay in making the application, grant the writ of *habeas corpus*. The writ must be obeyed, more or less promptly according to the distance; but in no case must the delay exceed twenty days. Any officer who refuses the prisoner a copy of the warrant of commitment, or who shifts the prisoner to another custody without authority, forfeits £100, and for the second offence £200, and is disabled to hold office. No person once delivered by *habeas corpus* may be recommitted for the same offence under a penalty of £500. A person committed for treason or felony may insist on being tried in the next term or session, or admitted to bail, unless the crown witnesses cannot be ready: if not tried in the second term or session he must be discharged. Any judge who denies the writ forfeits £500. This is now the only case in which a private person may take proceedings against a judge in respect of an act done in his judicial capacity.

The Habeas Corpus Act extends only to the cases of persons imprisoned on criminal charges; but in 1816 its provisions were extended to other cases by the 56 Geo. III. chap. 100. The result of these enactments is that in all cases where any person, whether man, woman, or child, is deprived of liberty, some friend may apply for a *habeas corpus* directed to the officer or private person having custody of the prisoner. Refusal to make any return to the writ will of course be dealt with as contempt of court. If the party is detained by lawful authority (e.g. in the case of a child in the care of its parents, or a dangerous lunatic privately kept under restraint by his friends) the facts must be stated in the return. If the alleged authority is of a formal character (e.g. a warrant of commitment, or a certificate of lunacy) it must be produced, and the court will judge of its legal sufficiency. A writ of *habeas corpus* runs in any county palatine or privileged place, in the Channel Islands, and the Isle of Man. In the case of Anderson, a slave who in 1853 had escaped to Canada after killing a Missouri planter, it was held that the writ might be applied for by a person confined in a colony; but an act passed in 1862 provides that the writ shall not run in any colony where there is a court having authority to grant a *habeas corpus*.

The law of *habeas corpus* does not extend to Scotland; but the subject is protected by the Wrongous Imprisonment Act, 1701, chap. 6, which is often called the Scotch Habeas Corpus Act. In Ireland there was no Habeas Corpus Act until 1783; and the provisions of the law then passed have frequently been suspended by acts arming the government with exceptional powers. The protection of *habeas corpus* is secured to American citizens by the constitution of the United States, and by the constitution of most of the states. The state courts do not discharge persons imprisoned by order of federal courts; nor will the federal courts interfere with persons imprisoned under state process.

In times of rebellion or disturbance the government may find it necessary to arrest dangerous persons, and to detain them in custody without bringing them to trial. In such cases the government may either break the law and apply to parliament for an Act of Indemnity, or it may invite parliament to suspend the Habeas Corpus Act for a time. In 1881, for example, the Irish government was empowered to detain without trial all persons reasonably suspected of complicity in treason and crime. In the United States, Merryman's case, in 1867, gave rise to a keen discussion, some eminent lawyers maintaining that the president, of his own authority, could suspend the law of *habeas corpus*, others contending that the power of suspension could only be exercised by congress. For the history and law of Habeas Corpus, see Blackstone's *Commentaries*, Hallam's *Constitutional History*, Story's *Commentaries on the Constitution of the United States*, &c.

Habergeon. See HAUBERK, ARMOUR.

Habington. WILLIAM, poet, was born at Hendlip in Worcestershire, November 4, 1605. His family was Catholic; his uncle was executed, and his father lay six years in the Tower, for complicity in Babington's plot. He was educated at St Omer, but declined to become a Jesuit, and was next sent to Paris. He married Lucy Herbert, daughter of the first Lord Powis, and has immortalised her in his *Castara*, a collection of lyrical poems, some of rare beauty and sweetness, and stamped throughout with a purity then unusual. It was first published in quarto in 1634. His father died in 1647, and he himself, says Wood, 'who did then run with the times and was not unknown to Oliver the usurper, died on the 30th of November 1654.' Other works of Habington were *The Historie of Edward the Fourth* (1640); *The Queene of Arragon, a Tragicomedie* (1640); and *Observations upon Historie* (1641).

Habit. See HEREDITY, INSTINCT, REFLEX ACTION, VARIATION, ASSOCIATION OF IDEAS, CAUSALITY, ETHICS.

Habit and Repute, a phrase used in Scotch law to denote something so notorious that it affords strong and generally conclusive evidence of the facts to which it refers. The best-known example of this is where a man and woman cohabit as husband and wife, and are reputed by the neighbours to be married, in which case the law of Scotland accepts the cohabitation and the proof by public opinion as evidence that a marriage has been contracted by the parties by the interchange of consent. In England no such doctrine prevails, and the marriage would have to be proved in the usual way, if called in question, by a suit which directly raises such question, though the parties had all their lives lived together as man and wife.—There is also in Scotland an application of the doctrine of habit and repute to persons when convicted of stealing; for if the individual is a habit and repute thief—i.e. a notorious thief—the repute that the accused gets his livelihood or supplements it by thieving is technically an aggravation of the offence, and may be charged and proved as such; nor is it necessary to the establishment of such a charge that the accused should have been previously convicted. In England and Scotland a somewhat similar effect is produced more circuitously, by proving that the thief has been several times previously convicted (is a 'habitual criminal'), in which case he is generally punished by a severer sentence.

Habitual Drunkards. See INEBRIATES.

Habsburg. See HAPSBURG.

Hachette, LOUIS, French publisher, was born at Rethel in the Ardennes, on 5th May 1800. In 1826 he established in Paris a publishing business, principally with the intention of issuing books calculated to improve school teaching and elevate the general intelligence. In pursuance of his plan he has published several series of books, as the *Bibliothèque populaire*, *Bibliothèque variée*, &c., which have done most useful service in disseminating information and amusement among the people. He also deserves to be mentioned as a friend of the

working classes, and as the promoter of international copyright. He died 31st July 1864.

Hackee, a name for the Chipmunk (q.v.).

Häckel, Ernst. See Haeckel.

Hackberry, See Nettle Tree.

Hackbut. See Firearms.

Hackensack, a post-village, capital of Bergen county, New Jersey, on the Hackensack River, 12 miles by rail N. of Jersey City. It has several factories. Pop. 4983.

Hackländer, Friedrich Wilhelm von, a German novelist and comedy writer, was born at Burtscheid, near Aix-la-Chapelle, 1st November 1816. After one or two false starts in life, he commenced his literary career with *Bilder aus dem Soldatenleben* (1841), and three years later followed up his success with *Das Soldatenleben im Frieden* (9th ed. 1883). The truth and pleasant humour of these books induced Baron von Taubenheim to invite Hackländer to accompany him on his travels to the East. The literary fruits of this journey were *Daguerreotypen, aufgenommen auf einer Reise in den Orient* (2 vols. 1842), and *Pilgerzug nach Mekka* (1847; 3d ed. 1881), a collection of oriental tales and legends. In 1843 he was appointed private secretary to the crown-prince of Würtemberg, with whom he travelled in the succeeding years. In March 1849 he went to Italy, was present with Radetzky's army during the campaign in Piedmont, and afterwards published *Soldatenleben im Kriege* (2 vols. 1849–50). From 1859 onwards he lived for the most part in Stuttgart, partly also at Leoni on Lake Starnberg (or Würm) near Munich, and died at the latter place, 6th July 1877. The best of his longer novels are *Handel und Wandel* (1850; 3d ed. 1869), *Eugen Stillfried* (1852), and *Namenlose Geschichten* (1851). Accurate portraiture of actual life, mostly its external aspects, and a genial humour are the most outstanding characteristics of these works. His best comedies are the *Geheimer Agent* (1850), which has been performed on all the stages of Germany, and translated into several European languages, and *Magnetische Curen* (1851). Along with Zoller he started the illustrated magazine *Ueber Land und Meer*. A collected edition of his works was published at Stuttgart in 60 vols. 1855–74. See his posthumous *Roman meines Lebens* (2 vols. 1878).

Hackmatack, See Larch.

Hackney, a parish of Middlesex, now forming a suburb of London, and 3 miles NNE. of St Paul's. It was at one time a favourite suburban residence of the London citizens, but, the current of fashion having for many years been setting to the west, Hackney no longer holds the rank it formerly did. In its earlier and fashionable days it is by some said to have given its name to hackney-coaches. See Cabs.

Haco V., surnamed the Old, king of Norway from 1223 to 1263. During his reign Greenland and Iceland were added to the Norwegian crown. Haco died in the Orkneys on his way home from Scotland, where he had fought the battle of Largs (q.v.) against Alexander III. See Norway.

Haddington, the county town of Haddingtonshire, lies at the southern base of the Garleton Hills, on the Tyne, 17 miles E. of Edinburgh. Its Abbey Church, the *Lucerna Laudoniæ* or 'Lamp of Lothian,' is a cruciform Decorated red sandstone pile, with a central tower 90 feet high, and ruinous all but the nave (the parish church), restored 1891–92. Then there are the county buildings (1833), the large corn exchange (1854), the town-hall (1748–1831), the county lunatic asylum (1866), and a school, the Knox Memorial Institute (1880). Haddington's worthies have been Knox, John Brown and Samuel his grandson, Samuel Smiles, and Jane Welsh Carlyle, whilst its chief memories have been perils by flood and fire, and the great siege of the English by the Scotch in 1549. An ancient royal burgh, it united till 1885 with North Berwick, Dunbar, Jedburgh, and Lauder to return one member to parliament. Pop. (1831) 3857; (1881) 4043; (1891) 3770. See works by James Miller (1844) and John Martine (1883).

Haddingtonshire, or East Lothian, a maritime county of Scotland, washed on the north for 32 miles by the German Ocean and the Firth of Forth. Its utmost length is 26 miles, its utmost breadth 19, and its area 280 sq. m. In the south are the Lammermuir Hills, culminating in Lammer Law (1733 feet); whilst isolated heights are North Berwick Law (612), Traprain or Dumpender Law (724), and the Garleton Hills (594), on which stands a conspicuous column, erected in 1824 to the fourth Earl of Hopetoun. The Tyne, flowing 16 miles north-eastward through the county, is its only considerable stream. The rocks are variously Silurian, sandstone, volcanic, and carboniferous, and yield coal, iron, and limestone, the coal having been mined near Tranent since the 13th century. The annual rainfall is 25 inches, and the mean temperature 46° F. Thanks to a long series of skilled agriculturists, from John Cockburn of Ormiston to Mr Hope of Fenton Barns and onwards, Haddingtonshire has for two hundred years enjoyed high agricultural fame, having been the first Scottish county to adopt the sowing of turnips in drills (1734), the thrashing-machine (1787), and the steam-plough (1862). About 64 per cent. of the entire area is in cultivation, and more than one-seventeenth is under wood. The county returns one member to parliament. Its towns are Haddington, Dunbar, North Berwick, Prestonpans, Tranent, and East Linton; and under these and the Bass Rock are noticed the chief events in its history. The antiquities include the ruined castles of Dirleton and Tantallon. Pop. (1841) 35,886; (1881) 38,502; (1891) 37,491. See Lothian, and works by D. Croal (3d ed. 1885) and J. Small (1883).

Haddock (*Gadus æglefinus*), a fish of the same genus with the cod, and much resembling it in general appearance. The number of fins is the same as in the cod, there being three dorsals and two anals. The haddock, like the cod, has a barbule at the point of the lower jaw. The haddock is brown on the back, silvery on the belly; the lateral line is black, and there is a black spot behind each of the pectorals, these spots sometimes extending so as to meet on the back. An ancient legend ascribes these spots to the finger and thumb of St Peter, and states the haddock to be the fish from the mouth of which he took the tribute-money, 'the inventors of the legend never adverting to the improbability of a marine fish living in the fresh-water lake of Gennesaret.' The haddock, indeed, is not found even in the Mediterranean. Nor does it enter the Baltic, although plentiful in the northern parts of the Atlantic Ocean, both on the European and the American coasts. On the British coasts it is abundant almost everywhere, appearing in great shoals at particular seasons, but in size and quality the haddocks taken at one part of the coast differ much from those of another. Those of the east coast, and particularly those caught in deep water, are in great esteem, and those of Dublin Bay are remarkable for their large size. A haddock of 16 lb. has been taken in Dublin Bay. Generally, however, this fish is much smaller. It is taken both by trawl-nets and lines. The usual bait for the long lines used to catch this fish on the east coast of Britain is mussel. The haddock, when

really of good quality, is perhaps the finest of all the Gadidæ; and the numbers taken on some parts of the British coasts are very great, rendering it, from an economical point of view, a very important fish. It does not 'take salt' so well as the cod, but is often cured by drying and smoking. In March and April the haddock is out of season; in October, November, December, and January it is in finest condition. Smoked *Finnan Haddocks* are named from the fishing village of Finnan or Findon (q.v.), in Kincardineshire.

Haddon Hall, an old English baronial mansion, the seat successively of Avenells, Vernons, and the Rutland family, stands on a slope overlooking the Wye in Derbyshire, 23 miles NNW. of Derby. The styles of architecture range from Norman to the 16th century. Reference is made to it in Scott's *Peveril of the Peak*. See two works with illustrations by Cattermole (1846-67); S. C. Hall's *Haddon Hall* (1871); *Quarterly Review* (1890); and *Haddon Hall, illust. by W. E. Cooke* (1892).

Hade. See DISLOCATION, ORE, DEPOSITS.

Haden, SIR FRANCIS SEYMOUR, who both by his writings and by the etching needle has contributed to the revival of interest in etching, was born in London on 16th September 1818. He is by profession a surgeon, and was in 1857 elected a Fellow of the Royal College of Surgeons. His work in connection with etching was undertaken tentatively in 1843, and earnestly in 1858, as a relaxation from professional labours. The *Etched Work of F. S. Haden* contains 185 plates from his hand; others have been published in *Etudes à l'Eau Forte* (1865-66). The chief qualities of his work are vigour and breadth. President of the Society of Painter Etchers, he was knighted in 1894, and has written *Etched Work of Rembrandt* (1879-80), *Lectures*, and *About Etching* (1881).

Hadersleben, or HADERSLEV, a town of Sleswick-Holstein, situated 32 miles N. of Flensborg, on the Hadersleben Föhrde, a narrow arm of the Little Belt. It has an iron-foundry, and machine and tobacco factories. Pop. 7635.

Hades, in Greek religion, the name applied to the kingdom of the under-world, the abode of the departed spirits or shades. Hades and Pluto (q.v.) are also personal names for its king. It is the Greek word by which the Septuagint translates the Hebrew *sheol*, the abode of the dead, in which sense it occurs frequently in the New Testament. See HELL.

Hadith. See MOHAMMED, SUNNITES.

Hadji. See HAJJ.

Hadleigh, a quaint old market-town of Suffolk, on the Bret, 9½ miles (12½ by a branch line) W. of Ipswich. Its chief buildings are the brick Rectory Tower (1495) and the noble parish church, with a spire 135 feet high. Formerly, from 1331, an important seat of the cloth-trade, Hadleigh was the scene of the death of the Danish king Guthrum (889), of the martyrdom of Dr Rowland Taylor (1555), and of the 'great conference' (1833) out of which grew the 'Tracts for the Times,' and at which Newman, Hurrell Froude, Trench, and Rose, the then rector, were present. Pop. of parish (1851) 3746; (1891) 3229.

Hadley, JAMES, an American philologist, was born at Fairfield, New York, 30th March 1821, graduated at Yale in 1842, was for six years tutor and assistant professor there, and was professor of Greek from 1851 until his death at New Haven, 14th November 1872. He was one of the American committee for the revision of the New Testament. Hadley published a Greek grammar and *Elements of the Greek Language* (1869); after his death a volume of lectures on Roman Law appeared, and a series of *Philological and Critical Essays* (1873; ed. by Professor W. D. Whitney).

Hadley, JOHN, an English mathematician, the inventor of Hadley's quadrant (see SEXTANT) and of a reflecting telescope (1723). The honour of having invented the sextant is claimed for Hadley, Godfrey, and Newton. Each seems, however, to have made his own discovery independently. Hadley described his instrument, which he called an 'octant,' to the Royal Society on 13th May 1731. He contributed several papers to the *Transactions* of the society from 1717 onwards. Born in 1682, he died 14th February 1744.

Hadramaut, the name commonly given to the coast region of South Arabia from Aden to Cape Ras-al-Hadd, but by modern Arab geographers restricted to the region lying approximately between 48° and 51° E. long. It consists of a plateau, parted from a mountain-chain, the barrier of the interior desert, by a complex of valleys. Commerce, agriculture, cattle breeding, and the chase are the chief occupations. The climate is dry but healthy. Pop. about 150,000. Nominally the people are subject to Turkey, but the social and political conditions of the district are very similar to those of the former feudalism of Europe. Chief towns, Saiun and Terim, the former the seat of a celebrated Arab seminary. See Van den Berg, *Le Hadhramout* (1886).

Hadrian, PUBLIUS ÆLIUS HADRIANUS, Roman emperor from 117 to 138 A.D., was born at Rome in 76. During the reign of Trajan, who was his guardian and kinsman, he filled several high offices in the state, and in his earlier life devoted himself with such ardour to the study of Greek as to earn the nickname of Græculus. He accompanied the emperor in his wars against Decebalus, where he distinguished himself by his bravery; and in 117, when Trajan set out on his return to Italy, he was left behind with the army as prefect of Syria. When the intelligence reached Antioch that Trajan had died in Cilicia on his journey home, Hadrian was proclaimed emperor by the army, August 11, 117 A.D. The state of the empire at the time was extremely critical. Insurrections had broken out in Egypt, Palestine, and Syria; Mœsia in the east and Mauritania in the west were both invaded by barbarian hordes; while the Parthians had once more asserted their independence, and won several successes over the imperial forces. Hadrian, perceiving the advantage of a peaceful policy, wisely resolved to limit the boundaries of the Roman dominion in the East, and concluded a peace with the Parthians, surrendering to them all the country beyond the Euphrates. After appeasing the Roxolani and Sarmatæ, who had made an inroad into Mœsia, he repaired to Rome, where he had been already acknowledged by the senate, established his authority by liberality towards the people, and suppressed with great severity a patrician conspiracy against his life. In the year 119, for the purpose of becoming acquainted with the state of the provinces, he commenced his celebrated journey, which he is said to have performed chiefly on foot, marching bareheaded 20 miles a day and sharing cheerfully the hard fare of the humblest soldier. He visited Gaul, Germany, Britain, where he built the famous wall extending from the Solway to the Tyne, Spain, Mauritania, Egypt, Asia Minor, and Greece, whence he returned to Rome after his circuit of the empire in 126 or 127 A.D., and received the title of *Pater Patriæ*. Hadrian spent the years 132 and 133 in Athens, which city he adorned with splendid and costly buildings. After once more visiting Syria and crushing a desperate Jewish revolt, he returned to Italy, and spent the last years of his life at Rome and at his splendid villa

at Tibur. During the severe illness which carried him off, July 10, 138, at Baiæ, he was subject to violent outbursts of cruelty, to which, as well as to jealousy and pleasure, he was naturally subject. After the death of Lucius Ceionius Commodus, whom he had adopted under the name of Lucius Ælius Verus, he appointed Titus Aurelius (afterwards the Emperor Antoninus Pius) his successor. During his reign the army was vigorously disciplined and reorganised, so that the barbarians were not likely to attribute Hadrian's conciliating and peaceful policy to fear or weakness. As a civil ruler he merits high praise for the just and comprehensive view he appears to have taken of his duties as a sovereign. Hence to him is attributed, more than to any other, the consolidation of the monarchical system of Rome. Hadrian also divided Italy into four parts under four consuls, to whom was entrusted the administration of justice. Hadrian had a passion for building: his most splendid edifices were the mausoleum called the *Moles Hadriani*, in Rome, the nucleus of the present castle of St Angelo, the Ælian bridge leading to it, and the magnificent villa at Tibur. He likewise laid the foundation of several cities, the most important of which was Adrianopolis. He was a lover of the fine arts—in the history of which, as well as of jurisprudence, his reign forms an important era—of poetry, philosophy, and rhetoric, all of which he attempted. He set a high value on Greek literature, and likewise on the cultus of Greece, and caused himself to be initiated into the Eleusinian mysteries. No fragment of ancient literature has been more famous than the verses attributed to the dying Hadrian:

Animula vagula blandula
Hospes comesque corporis,
Quæ nunc abibis in loca?
Pallidula rigida nudula,
Nec ut soles dabis jocos.

Mr David Johnston, in his *Translations, literal and free, of the dying Hadrian's Address to his Soul* (privately printed, Bath, 1877), gives no fewer than 116 translations of all degrees of excellence. Many of these have read into the poem a kind of Christian or Neoplatonist spirituality which is not really in it, its aim being rather to emphasise the miserable state of the soul as soon as it ceases to enjoy the friendly hospitality of the body. Lord Carnarvon, in vol. iv. (1884–85) of *The National Review*, gives versions of it by Byron, Prior, two by Pope, one by Dean Merivale, and another by himself. Of these, Prior's is undoubtedly the best, although the freest rendering; Byron's, the poorest; while the second of Pope's—the well-known 'Vital spark of heav'nly flame'—is not properly a translation at all.

See Merivale's *History of the Romans under the Empire*, vol. viii.; W. W. Capes's *Age of the Antonines*, in 'Epochs of Ancient History;' Gregorovius, *Der Kaiser Hadrian* (1884); and Dürr, *Die Reisen des Kaisers Hadrian* (1881).

Hadrian's Wall. Before Agricola advanced into Scotland he planted some forts on the neck of land between the estuary of the Tyne and the Solway Firth, to protect him from attack in his rear and to secure the bringing up of supplies. He adopted the same precaution before leaving the Lowlands of Scotland for the Highlands, placing encampments between the firths of Forth and Clyde. Afterwards walls were constructed on these two lines. On the English side of the Border we find a stone wall with a ditch on its north side. Attached to it are stationary camps, mile-castles, and turrets for the accommodation of the soldiery who manned it. To the south of the stone wall is a series of ramparts generally called the *vallum*. This fortification consists of three aggers or mounds and a ditch. The military way along which the soldiery moved lies between the *murus* or stone wall and the vallum. The wall was not intended as a mere fence to block out the Caledonians, but as a line of military strategy. Every station and mile-castle has a wide gateway opening northwards. This does not look as if the Romans in the time of Hadrian had given up the country north of the wall to the enemy. Besides, two Roman roads, the

Map showing the line of Hadrian's Wall.

Watling Street and the Maiden Way, run past the wall into Scotland. On these ways were stationary camps, which have yielded inscriptions and coins considerably posterior to the time of Hadrian or Severus. A controversy long existed as to the time when the lines of fortification in the north of England were constructed. One great authority, the Rev. John Horsley, author of the *Britannia Romana* (1732), maintained that the north agger of the vallum was reared by Agricola, and that it was the road by which his forts were connected, that the ditch and the other two aggers were the work of Hadrian, and that the wall was reared by Severus. Stukeley (1687–1765), however, expressed the opinion that both vallum and murus 'were made at the same time, and by the same persons, and with the intent that the vallum should be a counterguard to the other, the whole included space being military ground.' Since Horsley's day inscriptions in honour of Hadrian have been found in four of the mile-castles in the central part of the line, and, as the mile-castles are an essential part of the wall, Hadrian is now generally believed to have been the builder of the whole structure. Severus, however, repaired it before he advanced into Scotland, where in three years he lost 50,000 men, and came back to York to die. Agricola came to Britain in 78 A.D. Hadrian came towards the close of 119 A.D. Severus died in 211 A.D. Towards the close of the 4th century Theodosius, for a brief period, reasserted the Roman dominion over the district between the walls of Antoninus (q.v.) and Hadrian, which, in honour of the Emperor Valens, obtained the name of Valentia. But this newly-established province was soon lost, and it was not long before the Romans finally abandoned Britain. Considerable portions of Hadrian's Wall yet remain. In two places the wall stands 9 feet high. See Collingwood Bruce, *The Roman Wall* (1851; 3d ed. 1866), and *Handbook to the Roman Wall* (1863; 5th ed. 1885); and Neilson, *Per Lineam Valli* (1891).

Hadrosaurus, the name given to a very large Dinosaurian (q.v.) of the Cretaceous epoch, whose remains have been found abundantly in New Jersey.

Haeckel, Ernst Heinrich, a distinguished German naturalist, born 16th February 1834, at Potsdam. He studied natural science and medicine at Würzburg, Berlin, and Vienna under Müller, Virchow, and Kölliker; and soon became distinguished for his enthusiasm and originality in zoological studies. After working for a while at Naples and Messina, he became a *privat-docent* in the university of Jena in 1861, a professor *extraordinarius* in 1862, and an ordinary professor of Zoology in 1865. In this position, in spite of other inducements, Haeckel has remained working indefatigably in his zoological institute, interrupted only by visits to the North Sea shores and the Mediterranean, or by more extended travels—e.g. to Madeira, the Canaries, Morocco, south Spain, Arabia, India, and Ceylon.

The most important of his numerous systematic works are the following: a monograph on the radiolarians (*Die Radiolarien*, 1862), with a superb atlas of 35 plates; the classic work on calcareous sponges (*Die Kalkschwämme*, 1872), important both in relation to these animals and in its practical illustration of general problems such as the nature of species; a yet larger work on jelly-fishes (*System der Medusen*, 1879), with an atlas of 40 plates, which like all Haeckel's work display inborn artistic talent unsurpassed among naturalists; several smaller works, such as that on the development and division of labour of the *Siphonophora* (1869), or that on the *Monera* (1870), in which he ranks under the title *Protista* the lowest forms of life which have not taken a decisive step towards plants or animals, or that on *Arabian Corals* (1876); and finally his monumental contributions to the *Challenger* Reports on *Deep-sea Medusæ* (1882), with 32 plates; on *Siphonophora* (1888), and especially on *Radiolaria* (1887), in three volumes, with 140 plates and 3500 new species.

With the above gigantic descriptive work Haeckel has combined two rarer accomplishments, successful generalisation and popular exposition. His *Generelle Morphologie* (2 vols. 1866), in its reasoned orderliness and clear generalisations, ranks beside Spencer's *Principles of Biology;* it is not only one of the very few works of moment on general morphology, but is greater than its name suggests, really including the gist of a series of treatises—e.g. on the commonly avoided subject of organic stereometry—the science of shape or promorphology, on the much-debated problem of individuality, on the various modes of reproduction, on heredity, and on the pedigrees of animals. Besides being one of the first to sketch the genealogical tree (*Stammbaum*) of animals, Haeckel gave precise and luminous expression to the general fact that the life-history of the individual is a more or less accurate recapitulation of its historic evolution. As a special application of this 'fundamental biogenetic law' his Gastræa-theory (elsewhere stated) is of paramount importance (see Embryology). Among other general works may be noted his *Perigenesis of the Plastidules* (1876), an ingenious contribution to the theory of Heredity (q.v.), and his speculations on the origin and development of animal tissues (1884).

Apart from detailed zoological work, Haeckel has devoted his life to applying the doctrine of evolution and to making it current coin. Owing much of his motive to Darwin, he stood for a time almost alone in Germany in his championship of a theory not then popular. Before the publication of Darwin's *Descent of Man* Haeckel was the only naturalist who had clearly recognised the import of sexual selection, and of his *Natural History of Creation* Darwin says, 'If this work had appeared before my essay had been written, I should probably never have completed it.' His most important expository works are the above-mentioned *Natürliche Schöpfungsgeschichte* (1st ed. 1868; 8th ed. 1889), which has been translated into twelve languages; 'The Evolution of Man' (*Anthropogenie*, 1874; 3d ed. 1877); and lectures on development and evolution, *Gesammelte populäre Vorträge aus dem Gebiete der Entwickelungslehre* (1878-79). Haeckel's popular works are very brilliantly written, but they are not always so careful in statement as Darwin's classics, and offend many by their remorseless consistency, and by their impatience with theological dogma and teleological interpretation. He has always been set against compromise, defending the freedom of science in a famous pamphlet (*Freie Wissenschaft und Freie Lehre*) written in answer to Virchow. Other works are *Die Medusen* (1880); *Darwin, Goethe, und Lamarck* (1882); *Der Monismus* (1892); and *Systematische Phylogenie* (1894-95).

Like all other naturalists, he has made a few mistakes; there are hints both in some of his drawings and in some of his arguments of the dangers of artistic and speculative imagination; and it may be doubted whether his early championship of evolution and Darwinism has not resulted in a taint of dogmatism in what is sometimes called 'Haeckelismus.' On the other hand, the thoroughness of his systematic labours, the excellence of his draughtsmanship, the clear generalisations of his *Generelle Morphologie*, the geniality of his teaching, and perhaps above all the courage, lucidity, and eloquence of his popular expository work on evolution have raised Haeckel to a pre-eminent position among modern naturalists. See Biology, Darwinian Theory, Embryology, Evolution, Heredity, Zoology.

Hæmatemesis (Gr. *haima*, 'blood,' and *emesis*, 'vomiting'), the ejection of blood from the stomach by vomiting. Its most common causes are gastric ulcer; congestion of the stomach or the neighbouring portions of the alimentary canal (see Stomach, Diseases of); and certain conditions of the blood, as in yellow fever, purpura, and sometimes in typhus. See Bleeding.

Hæmatite (Gr. *haima*, 'blood'), a mineral consisting chiefly of peroxide of iron, is a valuable iron ore. There are two principal varieties, Red Hæmatite and Brown Hæmatite. See Iron.

Hæmatocele (Gr. *haima*, 'blood,' and *kēlē*, 'tumour'), a tumour containing blood; opposed to Hydrocele (q.v.).

Hæmatoxylin. See Logwood.

Hæmatozoa (Gr. *haima*, 'blood,' and *zoon*, 'an animal'), parasites occurring in the blood. (*a*) Some Gregarines (q.v.) live in the blood-corpuscles of frogs, reptiles, and birds. (*b*) A few Nematodes occur in the vascular system—e.g. *Filaria immitis*, in the heart of the dog; *Strongylus armatus*, causing abdominal aneurism, in horse and ass; *Filaria sanguinis hominis*, which in Australia, China, India, Egypt, and Brazil occurs in man, the sexual female in the lymph glands causing Elephantiasis (q.v.), &c., the embryos circulating in the blood and causing hæmaturia, &c., while the larval asexual stages occur within a mosquito. (*c*) A very important blood parasite among Trematodes is Bilharzia (q.v.), occurring in Africa, in the blood-vessels of the bladder, mesentery, and portal system of man. See Bilharzia, Gregarine, Nematode, Parasitism; also Leuckart's *Parasites of Man*, trans. by W. E. Hoyle (Edin. 1886).

Hæmaturia (Gr. *haima*, 'blood,' and *ouron*, 'urine'), the discharge of blood with the urine, usually from disease of the kidneys or bladder. It

is rather a symptom than a disease, and, although always of some gravity, it is not very often directly fatal. Where it is necessary to treat the symptom itself complete rest is very important; the bowels may require to be freely moved; and styptics, such as ergot or perchloride of iron, may be taken by the mouth, the former in thirty-drop doses of the liquid extract, the latter in twenty-drop doses of the tincture, every two or three hours.

Hæmodoraceæ, an order of monocotyledons, consisting of herbaceous plants with fibrous roots and sword-shaped leaves; differing from Iridaceæ in habit, and in having the stamens six in number, or, if only three, opposite to the petals. There are about fifty known species, chiefly natives of America, South Africa, and Australia. Some of them have beautiful liliaceous flowers. A red colour exists in the roots of some; hence the name Blood-root has been given to them (see SANGUINARIA). In this order are ranked the Vellozias or Tree-lilies.

Hæmoglobin. See BLOOD.

Hæmophilia, or the *hæmorrhagic diathesis*, is the name applied to a constitutional peculiarity which manifests itself in a tendency to excessive bleeding when any blood-vessel is injured. In those who suffer from it (*bleeders*) a slight bruise may cause extensive extravasation of blood; a small cut or the extraction of a tooth may lead to dangerous or even fatal hæmorrhage. It is not known whether it is to the blood or the blood-vessels of those affected that the faulty arrest of bleeding is due. The condition is strongly hereditary; and, though it rarely affects women, is often transmitted in the female line. No cure is known for it.

Hæmoptysis (Gr. *ptusis*, 'spitting'), expectoration of blood, a symptom of disease of the lungs or heart, in all cases of great importance, and requiring immediate attention, but apt to be viewed popularly with a somewhat exaggerated alarm. It is seldom directly fatal, but it is often the first announcement of phthisis, and it is a matter of common prudence to seek medical advice on the appearance of even the slightest tinge of blood in the expectoration. Blood which comes from the lungs is *coughed* up, and it is generally bright and frothy. Blood from the stomach is *vomited*, and has the appearance of coffee grounds or hare soup from the action of the gastric juice on it. See BLEEDING.

Hæmorrhage. See BLEEDING; and for hæmorrhagic diathesis, see DIATHESIS, HÆMOPHILIA.

Hæmorrhoids. See PILES.

Hæmus, MOUNT. See BALKAN.

Haff, a word derived from the Danish *hav*, meaning 'sea,' and used to designate three lagoons along the Prussian coast of the Baltic—viz. Stettiner or Pommersches Haff, Frisches Haff, and Kurisches Haff. Haff-fishing or haaf-fishing is a term used by the Shetlanders to signify deep-sea fishing.

Háfiz, the poetical name of Shems ed-Dín (i.e. Sun of the Faith) Muhammed, the greatest of Persian lyrical poets, was born at Shíráz, where he passed all his life and died, according to the inscription on his tomb, 791 A.H. (1388 A.D.), though the year of his death is also given by different authors as 792 and 794 A.H. The date of his birth is not known. His *takhallus* Háfiz signifies one who is learned in the Koran and the *Hadíths*, or sayings ascribed to Mohammed. Little is recorded of his life, which, indeed, seems to have been uneventful. It is probable that he was married, but nothing is known regarding his domestic life. It would appear, from an anecdote related by Ferishtah, that Háfiz once intended making a long and distant journey, notwithstanding his stay-at-home proclivities. The sultan Mahmúd Sháh Bahmaní, who ruled in the Deccan, invited the poet to his court, and accompanied his flattering invitation with a sum of money amply sufficient to defray his expenses. Háfiz had proceeded as far as Lár, on the direct route from Shíráz to Ormuz, a port on the Persian Gulf, whence he could obtain a much shorter and easier passage by sea to the Deccan, and there he met with an old friend, who had been recently plundered by a gang of robbers, and generously gave him a share of his money. A party of merchants conveyed him to Ormuz, where he embarked in a vessel bound for the Deccan. But before the anchor was weighed he was so much terrified at a storm which suddenly arose, that he abandoned his purpose and returned to Shíráz, after despatching a letter of apology to the chief vazír, together with an ode.

According to a curious legend, Háfiz obtained his poetical faculty from the mythical saint, or prophet, El-Khizar (so called from his *green* robe, the emblem of perennial youth), who appeared to him, after he had passed several nights in watching for the coming of that tutelary friend of the Faithful, and who bestowed on him a draught of the Water of Life, thus inspiring him with the gift of song. From the charming sweetness of his poetry, Háfiz was fondly styled by his admiring contemporaries *Chagarlab*, or Sugar-lip. His ghazals are, externally, all on sensuous subjects—wine, flowers, beautiful damsels, &c., and hence he is often termed by Europeans the Anacreon of Persia; but, while the common people, who have most of his verses by heart and constantly repeat them, regard them simply as love-songs, they yet possess an esoteric signification to the initiated, the objects of the physical world being employed to denote those which are visible only to the *inward* sight. That is to say, Háfiz, in common with nearly all the greater poets of Persia, was of the sect of Súfí philosophers, the mystics of Islám, who are altogether free from Mohammedan fanaticism, and 'claim to be in so intimate a communion with the Deity, through devotion and the cultivation of their higher and nobler feelings, that they can afford to rise superior to the petty details of dogma and superstition.' From the mystical element in his poems, Háfiz is also called *Lisán el-Ghayb* (the Voice of Mystery). But, apart from any esoteric signification, it has been well remarked that 'to ignore the fact that natural feelings and sentiments, the contemplation of natural beauty and the enjoyment of human, intellectual, and corporeal pleasures, suggested the various expressions of admiration, love, or wit which these poems contain, would be contrary to the dictates of common sense.' In short, the key to the interpretation of the songs of Háfiz is to be sought in a combination of materialism and súfiism.

Sir Gore Ouseley has remarked that the style of Háfiz 'is clear, unaffected, and harmonious, displaying at the same time great learning, matured science, and intimate knowledge of the hidden as well as the apparent nature of things; but, above all, a fascination of expression unequalled by any other [? Persian lyrical] poet.' The name of Háfiz is a household word throughout Persia, and his songs are cited in every social assembly, so that he who can most frequently quote from Háfiz a passage appropriate to the subject of conversation is held in the highest esteem and admiration. Indeed such reputation did his ghazals acquire that his *Díván*, or collection, was resorted to in order to gather from it *fatwas*, or decrees of fate and judicial decisions, in like manner as the *Sortes Virgilianæ* were practised in Europe during medieval times.

If we may credit popular tradition, at the death of Hafiz the 'rigidly orthodox' objected to the interment of his corpse with the customary ceremonies, because of the loose tone of many of his odes, and his alleged scepticism, if not rank infidelity. But some of his friends procured an appeal to the poet's *Divan*, which opened at a passage that set all doubts as to his orthodoxy at rest:

> Even though far away from the bier of Hafiz
> Ye may mourn, he cannot be a hardened sinner.
> Peace!

It is generally believed that Hafiz lived to a good old age, although the date of his birth is not recorded. His tomb, which is situated some two miles north-east of Shiraz, has been most magnificently adorned by princes and wealthy vazirs, and is visited by numerous pilgrims and others from all parts of Persia.

The odes of Hafiz were first collected by Kasim Anvari, after the poet's death. Many editions of the Persian text have been printed, among which the most important are the following: by Abu Salih Khan Ispahani at Calcutta (1791); by G. Jervis and others at Bombay (1828); an edition printed at Cawnpore (1834), and one at Bulak (1834), and again in 1840. A valuable edition of the text by Brockhaus, in 3 vols., was published at Leipzig (1854–61). Von Rosenzweig-Schwannau published at Vienna a German translation of the greater portion of the poems (3 vols. 1858–64). The earliest rendering of a selection of the ghazals of Hafiz was published at Vienna in 1771, in Latin by Reviczki, and from it Richardson chiefly translated his *Specimen of Persian Poetry, or Ten Odes of Hafiz* (1802). There are other English renderings of some of the odes by Nott (1787), Hindley (1800), Rousseau (1801), Sir William Ouseley (1797–98), Bicknell (1875), Love (1877), and S. R. [Robinson] (1879). In 1891 Lieutenant-colonel Wilberforce Clarke published a complete English prose rendering of the *Divan-i-Hafiz*, in 1881 Professor Palmer had contemplated an English metrical translation of the entire *Divan*. There are also German versions of some of the poems by Von Hammer (1813), Daumer (1846), and Nesselmann (1865).

Hag, one of the vernacular names for the *Myxine glutinosa L.*, one of the Cyclostomata or Round mouths, allied to the lamprey. It is common off the coasts of the north of England, Scotland, and Norway, and of the North Atlantic generally, living in muddy ground at a depth of 40 to 345 fathoms. The mouth is a hollow suctorial disc, furnished with a single tooth above and two rows of strong, pointed, horny teeth below. There is a single nasal aperture above the mouth, which communicates with the pharynx. Round the nostril and mouth are four pairs of short barbules or tentacles. The body is

Hag.

eel-shaped, with no lateral fins, but a slight median fin round the tail. There are no bones; the backbone is represented by a persistent notochord with a cartilaginous sheath; the skull and mouth skeleton are also cartilaginous. There are six gill pouches on each side, communicating internally by as many short tubes with the gullet, and externally giving off six longer tubes which unite and open by a single external aperture in each side of the body at some distance from the head. No eyes externally; mere rudiments internally. The intestine is straight. On each side of the ventral median line are a series of cutaneous glands which secrete large quantities of gelatinous slime. There are no genital ducts. The eggs are of very large size, and when expelled from the ovary are contained in a horny egg-membrane; their shape is an elongated ellipsoid, at each end of which are a number of fine knobbed processes of the horny case, by which the eggs become entangled together. In the young state the animals are hermaphrodite, and contain immature eggs and ripe milt; when older they produce eggs only. The fish is about 15 inches in length when adult, and of a livid red colour. There are no scales. The Myxine, when not feeding, lies buried in the mud, with only the single nostril protruded, and a respiratory current of water passes through this nostril to the gill-pouches, escaping again by the branchial aperture. These creatures are often caught in very large numbers on haddock-lines (long lines). They gorge the bait (mussels) down into their stomachs. They also attack fish (cod, haddock) hooked on the lines, and devour all the flesh, leaving the skin and skeleton. They probably attack living fish (Gadidæ) in the same way, but evidence on this point does not seem very certain. Three species are known—the North Atlantic one mentioned, another from Japan, and another from Magellan Strait. Bdellostoma, which is closely allied, has six or more separate external branchial openings on each side, and is larger. Two species are known; one is common at the Cape. Nansen, while he was still at Bergen, described the hagfish as a hermaphrodite 'in a transition stage,' for according to his researches the animal is a *male* until it attains a certain size, and thereafter a *female*, or in some cases a hermaphrodite.

Hagedorn, Friedrich von, poet, was born 23d April 1708, at Hamburg, studied at Jena, and in 1733 became secretary to an old trading company at Hamburg called the 'English Court.' He died 28th October 1754. His poetry consists mainly of light satire, narrative, and 'society' verses. Since 1756 there have been many collected editions of his poems (as in 1825, 5 vols.). See works by Schuster (1883) and Eigenbrodt (1884).

Hagen, an industrial town of Prussia, in the Ruhr coal district of Westphalia, 12 miles NE. of Elberfeld-Barmen. It carries on a great deal of puddling and iron-founding, and has manufactures of iron, steel, and tin goods, cotton, cloth, leather, paper, beer, and tobacco. Pop. (1875) 24,290; (1885) 29,611; (1895) 41,833.

Hagenau, a town of Alsace-Lorraine, situated in the Hagenau forest, on the Moder, 21 miles by rail N. by E. of Strasburg, manufactures porcelain stoves, and has cotton and woollen spinning. The chief trade is in hops and wine. The Romanesque church of St George dates from the 12th century, and the Gothic church of Nicholas from the 13th. Having been invested with town rights by Frederick Barbarossa in 1164, it was made a free imperial city in 1257. By the treaty of Westphalia (1648) it was given up to France, and in 1871 finally returned to Germany. Pop. (1875) 11,726; (1885) 13,460.

Hagenbach, Karl Rudolf, theologian, was born 4th March 1801, at Basel. While at the universities of Bonn and Berlin, where he studied theology, he was principally influenced by Schleiermacher and Neander; and on his return to Basel he received a fresh impulse from his intercourse with De Wette. From 1824 he occupied a chair of Theology in his native town, and died there, 7th June 1874. The subjects he taught were the history of dogma and of the church; in respect of

this latter he wrote and taught as an adherent of the 'mediation' school of German theology. His numerous books on church history were issued as one uniform work, *Kirchengeschichte von der ältesten Zeit bis zum 19 Jahrhundert* (7 vols. 1868–72; 2d ed. 1885 *sq.*). Besides this he also wrote *Lehrbuch der Dogmengeschichte* (2 vols. 1840; Eng. trans.); *Encyklopadie und Methodologie der theologischen Wissenschaften*, one of the most useful manuals for the student of German theology, which in 1884 reached an 11th edition (by Kautsch); nine vols. of *Sermons*; biographies of Œcolampadius and Myconius (1859); a memorial of De Wette (1850); *Religionsunterricht an höheren Gymnasien* (6th ed. 1881); *Die theologische Schule Basels* (1860); and also two small volumes of poetry.

Hagerstown, capital of Washington county, Maryland, on Antietam Creek, 85 miles WNW. of Baltimore by rail. It has machine-shops, flour-mills, and manufactories of furniture and other wooden wares, fertilisers, farming implements, and cigars. Pop. (1890) 10,118.

Haggada. See EXEGESIS, TALMUD.

Haggai (Heb., 'born on a festival'), one of the minor prophets of the Old Testament. He was among those who returned from the Babylonian exile with Zerubbabel and Joshua. The building of the temple begun by them had for some time been at a stand-still, and several years of scarcity had followed. In the second year of Darius (520) Haggai prophesied that the dearth was due to the divine displeasure with the settlers for adorning their own houses while the house of God remained unfinished. The personal history of Haggai beyond what is given in his book is unknown. His prophecy is entirely connected with the construction of the temple, and closes with a promise to Zerubbabel, in whom he appears to have expected the fulfilment of the promises of the prophets regarding the ideal son of David. His style is monotonous and weak, which some have ascribed to the pressure of troublous times, others to his advanced age, concluding from ii. 3 that he was among those who seventy years before were carried into exile and had seen the old temple. There are commentaries by Hitzig (3d ed. 1863; 4th ed. by Steiner, 1881), Ewald (1867; in vol. v. of Eng. trans. of his *Prophets*, 1878), Keil (2d ed. 1873), Reinke (1868), and Van Eaton (Lectures, ed. by Robinson, Pittsburg, 1883).

Haggard, HENRY RIDER, novelist, was born of a good Norfolk family at Bradenham Hall, June 22, 1856, and was educated at Ipswich grammar-school. He went out to Natal in 1875 as secretary to Sir Henry Bulwer, and next year accompanied Sir Theophilus Shepstone to the Transvaal, where he served until 1879, when he returned to England to marry and settle down to a literary life. His first book, *Cetewayo and his White Neighbours* (1882), pleased the Cape politicians, but attracted no attention elsewhere. It was in a new kind of fiction that he was to make his successes. However, his *Dawn* (1884) and *The Witch's Head* (1885) were only successful after the immediate, extraordinary, and not undeserved popularity of *King Solomon's Mines* (1885). This was too quickly followed by *She* (1887), *Jess* (1887), *Allan Quatermain* (1887), *Maiwa's Revenge* (1888), *Mr Meeson's Will* (1888), *Cleopatra* (1889), *Allan's Wife* (1890), *Nada the Lily*, *Eric*, *Montezuma's Daughter*, *Joan Haste*, &c. Haggard has fertile invention, vigour, and novelty enough, but not the rare faculty of making things seem true; while his style is crude and lacks in distinction, his grasp of character is feeble. His fights indeed are powerful but not Homeric, and reek with needless blood and artificial gruesomeness; his pages are bright with vivid but somewhat garish African colours. His chief merit is his readableness; his greatest praise his phenomenal success; for with all his gifts he is still but little of the artist, and hardly to be taken seriously as a novelist.

Haggis, a Scotch dish, called by Burns the 'great chieftain o' the puddin' race,' is usually made with the large stomach-bag of a sheep, also one of the smaller bags called the king's hood, together with the lights, the liver, and the heart. After the stomach-bags have been well cleansed, the small bag is boiled along with the pluck. A quarter of the liver is now grated down, and the heart, lights, and small bag are minced very fine along with a large onion and enough beef-suet to moisten the meal. Two small teacupfuls of oatmeal previously crisped before the fire are added, with salt, and black and Jamaica pepper. The whole is now stirred together, and put in the large bag, which, however, must not be much more than half filled; it is sewed up, and afterwards boiled for about three hours.

Hagiographa. See BIBLE.

Hagiology. See SAINT.

Hague, THE (Dutch *'s Gravenhage*, 'the count's hedge'), the capital of the Netherlands, and the residence of the court, stands 2 miles from the North Sea and 15 NNW. of Rotterdam. It is one of the handsomest cities in the country, being intersected by canals and shady avenues of lime-trees, and having many fine public buildings and private houses. In the centre of the city is the Vijver, or Fish-pond, to the south of which stands the old castle of the counts of Holland. It consists of two courts, an outer and an inner; in this latter are the 13th-century Gothic knight's hall and the chambers in which the Dutch parliament holds its sittings. On one side of the outer court (*Buitenhof*) stands the gate-tower, which was formerly used as a state-prison, and in which the brothers De Witt were confined till dragged thence and torn to pieces by the populace (1672). The most noteworthy amongst the public buildings and institutions of the place are the picture-gallery, with a splendid collection of works by native painters (Paul Potter's 'Bull' and Rembrandt's 'Lesson in Anatomy'); the royal library, with 200,000 volumes, 4000 MSS., and collections of coins and gems; the municipal museum, with several Dutch pictures; the Museum Meermanno-Westreenen, containing a collection of early printed books; the ethnographic museum, rich in Chinese and Japanese objects; the town-house; and the royal palaces. The church of St James is the most important ecclesiastical edifice; it dates from the 14th century, and is Gothic in style. The Hague is the seat of several learned societies, as the Indian Society and the Institute for the Language, Land, and People of the Dutch Indies. Amongst the numerous statues that adorn the city are those of William I. (two in number), William II., Spinoza, Bernhard of Saxe-Weimar, and the monument which commemorates the deliverance from the French. Close to the town is the beautiful pleasure-park called 'The Wood,' in which stands a royal residence (1647) with the magnificent so-called 'Orange Hall.' Ryswick, where the treaty of 1697 was signed, is in the immediate vicinity. The Hague is connected by beautiful roads with Scheveningen, a fashionable bathing-place on the coast of the North Sea, which is incorporated municipally with The Hague. The city owes its importance mainly to the fact that it is the residence of the court and the capital of the country; but it has also considerable manufacturing industry, as iron-founding, copper and lead smelting, cannon-founding, printing, furniture and

carriage making, and the manufacture of gold and silver lace. Pop. 1875, 109,254; (1891) 165,560. From 1250 a hunting lodge of the Counts of Holland. The Hague did not acquire importance until the 16th century; in 1527 it became the seat of the supreme court in Holland, in 1584 the place of assembly of the States of Holland and of the States-general; and it was also the residence of the stadtholders. There, too, numerous treaties have been signed and diplomatic conferences held, especially the Triple Alliance of 1668 and that of 1717.

Hahnemann, CHRISTIAN FRIEDRICH SAMUEL, the founder of the homœopathic method of treatment (see HOMŒOPATHY), was born at Meissen, in Saxony, April 10, 1755. Educated at the grammar school of Meissen, he entered the university of Leipzig at the age of twenty; and it was by teaching and translating books written in English, French, Italian, Latin, Greek, Hebrew, and Arabic that he supported himself while at the university. The reputation he had made for himself as a scholar while at Meissen procured for him a free admission to the university classes. From Leipzig he proceeded to Vienna for clinical study, where he was the favourite pupil of Von Quarin, physician to the Emperor Joseph. He then passed two years as physician and librarian to a nobleman residing in Transylvania, after which he entered and, in 1779, graduated at the university of Erlangen. During the following ten years he practised medicine and held several public appointments in Dresden and elsewhere, and then settled in a small village near Leipzig. His observation and practice had so fully convinced him, not only of the uselessness, but also of the injurious character of the prevailing methods of treatment, that he now abandoned all practice and devoted himself to chemical research and the translation into German of foreign scientific books. Of these, Cullen's *Materia Medica* was one. Feeling dissatisfied with his author's explanation of the *modus operandi* of bark in curing ague, it occurred to him to endeavour to find out what kind of action this drug had on persons in health. He accordingly took considerable doses of bark himself, when he observed that they caused some of the symptoms he had noted as being characteristic of ague in Transylvania. This experiment led to his interpreting the curative power of bark in this fever by the hypothesis that it 'overpowers and suppresses the intermittent fever by exciting a fever of its own of short duration.' This appears in one of his notes in his translation of Cullen. Thus, as Ameke remarks, 'he started with the idea of aiding the recuperative power by a medicinal excitant acting directly on the part affected.'

His experiment also convinced him that it was by ascertaining the effects a drug produced on healthy persons that its mode of action could most surely be ascertained. He therefore commenced a research into the records of medicine, examining the reports of cases of poisoning by individual drugs, and made experiments with other drugs upon himself and his friends. He then studied all the cases of cure by these same drugs that he could find. In these investigations he occupied six years. They proved to him that, whatever might be the truth of the theory the bark experiment had suggested, the fact was that in all instances the medicine which had cured produced a very similar condition in healthy persons to that it had relieved. This conclusion he published in an essay in *Hufeland's Journal* in 1796, having the title of 'A New Principle for ascertaining the Curative Properties of Drugs.' It is in this essay that the principle or rule of *similia similibus curantur* is first put forward by him, not as a theory but as a fact. His views at once met with vehement opposition. His denunciation of blood-letting and other violent modes of treatment aroused the animosity of physicians, while the very small doses of medicine which alone were needed according to his new method, provoked the apothecaries, whose trade interests were threatened. They refused to dispense his prescriptions, and he accordingly gave his medicines to his patients without any charge. For a physician to dispense his own medicine was an infringement of the rights and privileges which German law had conferred upon the apothecaries, and hence he was prosecuted in every town in which he attempted to settle from 1798 until 1810, when he returned to Leipzig. Two years afterwards he was appointed a *privat docent* or extra-academical lecturer of the university. The thesis he defended before the Faculty, when a candidate for this position, has been described as 'remarkable for its display of extensive reading in the ancient authors, and not only those more immediately connected with his own professional pursuits, but also in the classical writers of antiquity.' At Leipzig he remained, teaching and developing his system of medicine to an ever-increasing band of enthusiastic disciples, and practising his profession uninfluenced by constantly recurring attacks from his professional neighbours until 1821, when a successful prosecution by the apothecaries for dispensing his own medicines drove him out of Leipzig. Under the protection of the Duke of Anhalt-Köthen he retired to Köthen, where he became a centre of attraction to numerous invalids in all parts of the world. His wife dying in 1831, in 1835 he married a French lady, who induced him to remove to Paris, where he resided and practised until his death, 2d July 1843.

Hahnemann is also known as one of the earliest advocates of hygiene. His book entitled *The Friend of Health*, published in 1792, proves him to have been very far in advance of his time on what is now called preventive medicine. Equally so was he in the treatment of the insane. His account of his successful treatment of a certain Hanoverian statesman, who, becoming maniacal, was placed under his care, shows that in 1794 he had adopted those principles of non-restraint and kindness in dealing with the insane which in later years were advocated by Pinel in Paris and Conolly in England. He was also the author of several valuable papers on chemistry in Crell's *Annalen der Chimie*—the first German periodical devoted to that science. A statue of Hahnemann was erected in Leipzig in 1851. See his Life by Albrecht (2d ed. Leip. 1875).

Hahn-Hahn, IDA, COUNTESS, authoress of a great number of German romances dealing with aristocratic circles of life, conventional in style and often sentimental in feeling, and of numerous books of travel, was born at Tressow, in Mecklenburg-Schwerin, 22d June 1805. At the age of twenty-one she married a relative; but the union was dissolved three years later. She thereupon travelled much in Europe and the East. In 1850, weary of her restless life, she embraced Roman Catholicism, and in 1852 entered a convent at Angers. Her later writings are strongly marked by ultramontane views. The best known of her novels are *Gräfin Faustine*, *Ulrich*, and *Clelia Conti*. Her style was cleverly satirised in Fanny Lewald's *Diogena* (1847). A collection of her early romances in 21 vols. appeared at Berlin in 1851. She died at Mainz, 12th January 1880.

Haidarabad. See HYDERABAD.

Haiduk, or HAJDUK (from a Hungarian word meaning 'drover,' 'cowherd'), the name given in Hungary to those who in the 16th century maintained a guerilla warfare against the Turks, from

the forests of eastern Hungary. In 1605 Stephen Boeskay, prince of Transylvania, established them in a district which he set apart for their occupation, on the left bank of the Theiss, gave them an independent constitution, and conferred upon them the privileges of hereditary nobility. This favoured position they retained until the conclusion of the war of 1849. The Haiduks are engaged almost exclusively in agriculture. In 1876 their country was incorporated in the county of Hajdu, with Debreczin as capital. The name was formerly borne by the Hungarian infantry of the line; and in the 18th century it was also applied to the retainers of the Hungarian magnates.

Haifa, a seaport of Syria, situated at the foot of Mount Carmel, a place of some 6000 inhabitants. A little distance to the north-west a settlement of the Würtemberg 'Society of the Temple' was founded in 1869, who now form a flourishing agricultural colony of 300 persons, chiefly engaged in cultivating the vine and growing fruits. Grain is exported. Gordon Pasha paid visits to Haifa, and here Laurence Oliphant settled in 1882. See his *Haifa, or Life in Modern Palestine* (1887). A railway from Haifa and Acre (on the other side of the bay) to Damascus was begun in 1892.

Haik. See ARMENIA.

Hail, Hailstorm. The word hail in English is used to denote two phenomena of quite different origin and formation. These have in recent years been distinguished as hard hail, or true hail; and soft hail, which denotes the fine, light grains, like small shot, that frequently fall in winter, much more rarely in summer, and are generally a precursor of snow. Soft hail is the *grésil* of the French, and the *graupel* of the Germans. The theory of the formation of soft hail has yet to be formulated. True hail is round, hard, compact, and formed of either clear or granular ice, the hailstones being often found when broken across to be composed of alternate layers of these two states of ice. It has a well-marked diurnal period, 80 per cent. of the whole number of hailstorms occurring in the six hours from 10 A.M. to 4 P.M., and only 8 per cent. in the fourteen hours from 6 P.M. to 8 A.M. The essential point to be noted in the diurnal period of hail is that the maximum period of hailstorms is two hours earlier than the maximum period of Thunderstorms (q.v.). The maximum period for thunderstorms is when the ascending current from the heated surface of the earth is at its greatest strength for the day; but the maximum period for hail occurs two hours before the ascending current has fully established itself, or it occurs at the time when atmospheric temperature and vapour diminish with the height at a much greater rate than the normal. In the higher latitudes the fall of hail may be regarded as restricted to the warmer months of the year; in countries where the summer is practically rainless no hail falls; and where the rainfall is small and at rare intervals very few cases of hail occur.

Hail is connected with whirlwinds, more or less developed; and it is when the hailstorm is an attendant on a tornado or on a great thunderstorm that it assumes its most destructive form, carrying devastation through a narrow belt of land usually of considerable length.

The theory of the formation of hail has been given by Ferrel in his *Meteorological Researches for the Use of the Coast Pilot*, part ii. p. 85. The vapour carried upwards by the vortical gyrations of the tornado is, below a certain height, condensed into cloud and rain; but above that height into snow. Now when the raindrops formed below are carried higher up into the cold snow regions by the powerful ascending currents of the tornado, and are kept suspended there a little while, they become frozen into clear hard hail. If these hailstones be now thrown quite outside the gyrations of the tornado, they fall to the earth as a shower of compact homogeneous hailstones of clear ice of ordinary size. But should they be caught in the descent and carried in towards the vortex by the inflowing aerial current on all sides, they are again rapidly carried aloft into the freezing region. A number of such revolutions of ascent and descent may be made before they ultimately fall to the earth. While high up in the snow region the hailstones receive a coating of snow; but while in the region lower down, where rain, yet unfrozen, is carried up, they receive a coating of solid ice. In this way alternate coatings of ice and snow are received, and the number of each sort indicates the number of ascents and descents performed before the hailstone falls to the ground. When the nucleus is compact snow, as it usually is, the hailstone has its origin high up in the snow region as a small ball of snow or soft hail.

From a well-known property of ice (regelation), the impinging hailstones are frequently frozen together not only in their course through the air, but also at the surface of the earth, giving rise occasionally to hailstones of larger dimensions. A curious instance of the fall of large hail, or rather ice-masses, occurred on one of Her Majesty's ships off the Cape in January 1860, when the stones were the size of half-bricks, and beat several of the crew off the rigging, doing serious injury. More than once in the summer of 1889 hailstones proved unusually destructive on the continent of Europe; in Moravia, for instance, where many stones fell as big as a man's fist, and weighing 3 lb., a number of people were killed in the fields, and many more were injured.

A description (taken from *Mém. de l'Acad. des Sciences*, 1790) of a most disastrous hailstorm may be here added. This storm passed over parts of Holland and France in July 1788. It travelled *simultaneously* along two lines nearly parallel—the eastern one had a breadth of from half a league to five leagues, the western of from three to five leagues. The space between was visited only by heavy rain; its breadth varied from three to five and a half leagues. At the outer border of each there was also heavy rain, but we are not told how far it extended. The general direction of the storm was from south-west to north-east. The length was at least a hundred leagues, probably two hundred. It seems to have originated near the Pyrenees, and to have travelled at a mean rate of about 16½ leagues per hour towards the Baltic, where it was lost sight of. The hail only fell for about seven and a half minutes at any one place, and the heaviest hailstones weighed about 9 ounces. This storm devastated 1039 parishes in France alone, doing damage to the extent of nearly a million of English money.

Hailes, LORD, the judicial title of Sir David Dalrymple, a well-known historical antiquary, born at Edinburgh, 28th October 1726. He was the grandson of Sir David Dalrymple, youngest and reputedly the ablest son of the first Viscount Stair. He was educated at Eton and Utrecht, whence he returned to Scotland in 1746, to be called to the Scottish bar two years later. Here his success was highly respectable, but not astonishing, as his extensive learning, sound judgment, and great industry were marred by indifferent oratory. In 1766 he was appointed one of the judges of the Court of Session, and assumed the title by which he is chiefly known to posterity. In this office his accuracy, diligence, judicial impartiality, and dignified demeanour secured him the highest respect, and ten years later he was made a justiciary lord. At his country-seat of New Hailes, five

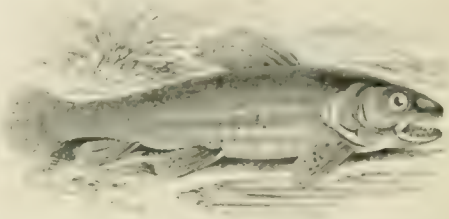
miles from Edinburgh, he gave his leisure to uninterrupted literary activity, on behalf of religion and in elucidation of early Scottish history. And though his official duties were arduous, he found time to compose numerous works, surpassing in value those of many men whose lives have been wholly devoted to literature. He was much esteemed by Dr Johnson, and corresponded with some of the greatest men of his time. He died 29th November 1792. His funeral sermon was preached by 'Jupiter' Carlyle; his appearance remains to us in a characteristic portrait by Kay.

Among his books are *Select Discourses, by John Smith of Cambridge* (1756); *A Discourse on the Grecian Constitution* (1757); *Memorials and Letters relating to the History of Britain in the Reign of James I.* (1762), a curious and interesting volume; *The Works of the ever-memorable Mr John Hales of Eton*, 3 vols. 1765; *Memorials and Letters relating to the History of Britain in the Reign of Charles I.* (1766); *Annals of Scotland from the Accession of Malcolm III., surnamed Canmore, to the Accession of Robert I.* 1776); and *Annals of Scotland from the Accession of Robert I., surnamed the Bruce, to the Accession of the House of Stuart* (1779). The last two form one continuous matter of fact history of the greatest possible value, which Dr Johnson valued above the 'painted histories more to the taste of our age.' Besides these, Dalrymple wrote works on legal antiquities and ancient church history, edited old Scotch poems, and published sketches of the lives of various notable Scotchmen, as specimens of how a *Biographia Scotica* might be executed.

Haileybury College. 2 miles SE. of Hertford, erected in 1809 by the East India Company from the design of William Wilkins, R.A., as a place of training for cadets in their service, and so occupied until the transference in 1858 of the powers of the Company to the crown. An interval then ensued during which the college remained absolutely empty, though the solitude was for a few months broken by the arrival of a regiment from India, fresh from the mutiny; but the building was not suited for barracks, and it was soon again deserted. For a while there was a talk of converting it into a workhouse, but happily a better fate was in store for the place: the enterprise of several county gentlemen successfully carried through a scheme for establishing at Haileybury a new public school, and in September 1862 the school was opened, its numbers being limited under its charter to 500. Five exhibitions of from £60 to £20, tenable for three years at Oxford or Cambridge, and in some cases elsewhere, are open yearly for competition to members of the school who are under nineteen years of age; another of £50 is available every third year, and there are nine scholarships for boys at the school. Among the professors on the staff of the East India Company were Malthus, the political economist; Sir James Mackintosh, the philosophical historian; William Empson, editor of the *Edinburgh Review*; and Sir Monier Monier Williams, Boden Sanscrit professor at Oxford; and among the students who afterwards became illustrious, John Lawrence, ruler of the Punjab in the time of the Indian Mutiny, afterwards Lord Lawrence, Viceroy of India; Sir Charles Trevelyan; Bishop Forbes; and Sir Henry Bartle Edward Frere. See Higgen, *Old and New Haileybury* (1887), and Monier Williams, *Reminiscences of Old Haileybury College* (1894).

Hail, Mary. See Ave Maria.

Haimura (*Erythrinus macrodon*), a large freshwater fish of Guiana, belonging to a small group of fishes (Erythrinina), family Characinidæ (Günther). It measures from 3½ to 4 feet in length; its flesh is firm, and well flavoured; and at times the fish is so abundant that it forms the principal article of food with the Indians, who capture it by hook or in an ingeniously contrived trap. It is very voracious. The jaws are very powerful, and the teeth are large and can inflict serious wounds: a man's hand has



Haimura.

been cut off by them. The haimura particularly abounds near rapids and falls in the upper parts of the rivers of Guiana.

Hainan, an island of China, the southernmost land of the empire, lying between the Gulf of Tong king and the China Sea, and 15 miles S. from the mainland. It forms part of the province of Kwangtung, and measures about 150 miles (from south-west to north-east) by 100. The centre and south of the island are mountainous; on the north the mountains are fringed with fertile plains, well watered by rivers. The island, which is purely agricultural, produces rice, sesamum-seeds, ground-nuts, sugar, sweet potatoes, taro, cocoa-nuts, indigo, beans, turnips, millet, pine-apples, and various kinds of vegetables. Exports—pigs, sugar, sesamum-seeds, ground-nut cakes, betel-nuts, and eggs; annual value, £316,450. Imports—opium, cotton and woollen goods, and rice; annual value, £410,000. The capital is Kiung-chow (pop. 40,000), the port of which, Hoi-how (15,000), 3 miles distant, has been open to foreign trade since 1876. The inhabitants number altogether about two and a half millions, the plains being inhabited by Chinese (1½ millions), the mountainous and unknown interior by the aboriginal Les. Eight to ten thousand Chinese emigrants leave Kiung-chow every year for Singapore and Bangkok. Plants and animals, especially birds and fishes, are numerous. Gold exists. The island is subject to frequent earthquakes, and in summer to typhoons. See B. C. Henry's *Ling-Nam* (1886).

Hainault (formerly spelt in a perplexing variety of ways from *Haysneaultx* to *Héno*; Ger. *Hennegau*), a southern province of Belgium. Area, 1437 sq. m.; pop. (1894) 1,082,494, principally Walloons. The surface consists in the north and west of flat and fruitful plains; the south is occupied by spurs of the Forest of Ardennes. The principal rivers are the Haine—from which the province has its name—the Scheldt, the Dender, and the Sambre, the last a tributary of the Meuse. The soil is highly productive; wheat and flax are very extensively grown. Valuable crops of fruit, vegetables, and beet are produced. Excellent breeds of horses, horned cattle, and sheep are reared. Toward the south and south-east, in the neighbourhood of Mons and Charleroi, are very extensive coalfields, from which about 2,000,000 tons of coal are annually extracted. Iron is also produced in considerable quantity, and marble, building-stone, and limestone are quarried. Linen, porcelain, iron and steel goods, lace, paper, leather, &c., are extensively manufactured. The capital is Mons. From the 9th century Hainault was the name of a countship, which embraced the modern districts of both French and Belgian Hainault. For many years (1030–1279) the history of the countship was closely connected with that of Flanders (q.v.). From 1345 to 1433 it belonged to the royal house of Bavaria, and then passed to Burgundy, the fortunes

of which duchy it shared down to the French Revolution. French Hainault (now the department of Nord) was, however, formed out of the county after the treaty of the Pyrenees (1659). The present Belgian province was constituted in 1815. For Hainault Forest, see EPPING.

Hainburg, a walled town of Austria, on the Danube, 27 miles ESE. of Vienna, with a royal tobacco factory. It is usually identified with the ancient *Carnuntum* (q.v.); and a Roman aqueduct still supplies its market-place with water. In the *Nibelungenlied* the castle of Hainburg is called Heimburc, the border fortress of the country of the Huns. It was taken from the Hungarians in 1042 by the Emperor Henry III., and afterwards became a residence of the Austrian princes. In 1482 it was stormed by Matthew Corvinus, in 1683 by the Turks; and in 1827 it was burned to the ground. Pop. 4857.

Hainichen, a town of Saxony, the centre of the German flannel manufacture, lies 13 miles NE. of Chemnitz. Besides its staple product, it also manufactures cloth, leather, chenille, and plush. Here Gellert was born in 1715. Pop. 8253.

Hair. With the exception of the palms of the hands and the soles of the feet, the human skin is almost everywhere studded over with hairs. In few localities, however, does the hair attain any degree of thickness or length. Except on the scalp, the male cheeks, &c., the hairs are fine, short, and scanty, but more apparent in the male than the female.

An individual hair may be regarded as consisting of a root, a shaft, and a point. The *root* is the short, soft bulbous portion which is withdrawn from the skin when a hair is plucked from the body; the *shaft* is the part which projects beyond the surface of the integument; and the *point* is its attenuated free extremity.

The root of the hair is enclosed within a minute tubular depression in the skin which is termed the *hair-follicle.* This is the chamber in which the hair is manufactured, and it is here also that additions are made to its root so that it increases in length. The skin is composed of two layers: an outer epidermis and an inner corium. The epidermis is the cellular protective layer, and the hair and nails may be regarded as outgrowths from it. Amongst the lower animals the claws, hoofs, spines, feathers, scales, &c. all belong to the same category—all, like the hair, are appendages of the epidermal layer of the skin. The corium is fibrous and vascular, and rests directly upon the fatty subcutaneous tissue of the body. Both layers of the skin take part in the formation of the hair-follicle. Its wall, therefore, has two distinct layers entering into its formation—the inner layer being cellular and epidermic, whilst the outer layer is fibrous and continuous with the corium. When a hair is wrenched out of its socket the inner layer of the follicle adheres to the root, and is in great part withdrawn with it. It is therefore termed the *root-sheath.* In the case of the short hairs the hair-follicles do not sink beyond the skin, but in the case of the head-hairs and beard they are much deeper, and penetrate into the subcutaneous fatty tissue.

The extremity of a fresh hair-root is expanded in the form of a knob, called the *hair-bulb.* This hair-bulb is composed of cells like those of the root-sheath, and at the bottom of the follicle the two are directly continuous with each other around the circumference of the bulb. Again, at the bottom of the hair-follicle there is a little fungiform projection continuous with the corium. It is called the *hair-papilla,* and is plentifully supplied with both blood-vessels and nerves. This papilla is of the utmost importance in connection with the process of hair-growth. It is also an agent in fixing the hair in its follicle, because the lower aspect of the hair-bulb is hollowed out into a cavity, and the papilla is received into this in the same manner as a head is received into a cap.

In structure a hair may be considered as being composed of three distinct parts. Its chief bulk consists of *fibrous substance;* this is coated on the outside by a thin scaly layer, termed the *hair-cuticle,* whilst its centre is traversed by a narrow cellular thread or core, which is termed the *medulla.* The hair-cuticle is exceedingly thin, and is formed by a single layer of minute flat scales deposited upon the surface of the hair. These scales overlap each other in an upward direction from the root to the point of the hair. The free uncovered margins of the cuticular scales therefore look upwards towards the point, and when examined under the microscope they appear on the surface of the hair in the form of wavy lines, and at the same time give to its outline a slightly toothed or serrated appearance. It is the arrangement of these scales which gives to hair its commercial value. It is due to them that the *felting* of hair is possible. But human hair is ill adapted for this purpose, because the cuticular scales are closely applied to the body of the hair. In wool, however, the scales stand well out, and the serrations are so distinct that the hairs interlock firmly the one with the other.

Fig. 1.
Vertical section of Skin, showing hair-follicle:
a, epidermis; *b*, hair; *c*, hair-bulb; *d*, *d*, oil-glands; *e*, fat-cells.

We have mentioned that the hair-root is attached to its follicle (1) by a continuity at the bottom of the follicle of the cells composing the hair-bulb and those forming the root-sheath, and (2) by the hair-bulb being moulded over the surface of the fungi-form hair-papilla. There is yet a third connection. The follicle is lined by delicate imbricated scales, which are directed downwards and interlock with the upwardly-directed scales which coat the hair-root.

The *fibrous substance* of the hair is composed of flattened fibres applied to each other in the longitudinal direction, and firmly united by intervening cement-substance. These fibres can be still further resolved into minute flattened elongated plates or cells, which constitute the ultimate elements of the fibrous substance. The pigment or colouring matter of the hair is distributed throughout the fibrous substance. It is partly placed within the cells which build up the fibres, and partly in the cement-substance which glues the cells together. But the colour of a hair is not entirely determined by the quantity or kind of pigment present. It is also to a certain extent determined by the presence of air which is contained in minute chinks or crannies in the fibrous substance. These air-spaces are numerous in white hairs, but are almost entirely absent in black hairs.

Fig. 2.
Surface of a human Hair, magnified.

The *central medulla* is not present in every hair, nor, indeed, is it to be found throughout the entire length of those hairs in which it exists. Thus it is absent in the fine short hairs of the body, and also

in a large proportion of the hairs of the scalp. In structure it consists of two or three rows of rectangular cells, which contain a certain amount of air.

The structure of human hair is such that it can almost always be distinguished from hair drawn from other sources. At the same time it should be noted that the hair of certain of the anthropoid apes, more especially the Chimpanzee and Gorilla, resembles it so closely, both in structure and in microscopical appearance, that the differentiation would be matter of extreme difficulty—if indeed it were possible. Waldeyer, in his *Atlas der Menschlichen und Thierischen Haare*, 1884, gives a series of beautiful illustrations in which the hair of man may be compared with that of certain of the lower animals.

In connection with each hair there is a remarkable contrivance by means of which it is kept smooth, glossy, and pliant. It is furnished with two or more oil glands, which secrete a greasy fluid. Each of these glands consists of a little sacculated pouch which opens into the hair-follicle near its orifice by a short duct or channel of exit. The oily matter which is formed in the gland is discharged into the hair-follicle, and thus upon the surface of the hair.

Hairs are likewise provided with minute muscles. These consist of slender bands of contractile tissue, which cross the obtuse angle which is formed by the hair-follicle and the surface of the skin. On the one hand this little muscle is attached to the superficial part of the true skin, and on the other to the lower end of the hair-follicle. They are not under the control of the will, but cold and certain emotions, such as horror and fear, will bring them into play. In such cases the hair-muscles contract; they straighten the hair-follicles and erect the hairs. The condition known as 'goose-skin' is the result.

The hair-follicle is the laboratory in which the manufacture and continued growth of the hair is effected. At the bottom of the follicle is the little papilla upon which the hair-bulb is moulded. The blood-vessels of the papilla supply the material necessary for the growth of the hair. Additions are made to its base, and as it rises up in the follicle its upwardly-directed scaly covering sweeps before it the scales lining the follicle. The scales which are thus carried to the surface constitute a part of the scurf of the head. The rate at which the hair grows differs very much in different parts of the body, and it is also said to be affected by the age of the individual, the age of the particular hair under investigation, the season of the year, and even the hour of the day. The average growth of the beard has been computed to be 6½ inches each year. In the growth of the head-hair the greatest discrepancies exist in the results obtained by different observers. In young females who have lost their hair by fevers it has been noticed to grow at the rate of 7 inches each year.

When the growth is good the average length of hair on the female head will be found to vary from 22 to 28 inches. Anything beyond this must be regarded as exceptional. Cases, it is true, are recorded in which it has measured from 5 to 6 feet; but these are very rare. In the 'Hair Court' of the 1862 international exhibition there was a specimen of jet-black hair measuring 74 inches. But most extraordinary instances are recorded of the power of hair-growth possessed by certain of the North American Indians. A chief of the Crow tribe is mentioned by Catlin as having hair of the almost incredible length of 10 feet 7 inches.

The duration of hair-life is limited, and sooner or later it is shed. Indeed it is stated that the hairs of an infant are completely shed within a year after birth; those on the body and limbs go first, whilst the hairs of the head and the eyelashes follow. This change is carried on almost imperceptibly, seeing that the place of the falling hairs is taken by a second crop. The process of loss and renewal is very simple. The old hair is detached from the papilla, and soon another hair makes its appearance at the bottom of the same follicle, and grows towards its orifice. The detached hair is thus thrust out and shed. The whole process is not unlike the replacement of the milk teeth in the child by the permanent teeth. The second crop of hair which appears is perennial. An eyelash has been calculated to remain attached for 110 days. A head-hair has a longer period of life. It lives from two to four years. Before it dies provision is made for its successor, and so the process of shedding and renewal goes on continually. During its life a hair is only capable of growing a certain determinate length. The circumstance which determines this length is the amount of nutritive material which can be drawn from the blood-vessels of the papilla. Thus when a hair has attained its full length it will resume growth for a second time on being cut short. It is only when the loss exceeds the powers of renewal that a tendency to baldness results. In the case of the female head the daily loss may contain a quarter of the hairs shed of a length under 6 inches without giving rise to apprehension. Should the number of fallen short hairs exceed this proportion the hair-loss is abnormal, and baldness is likely to ensue.

As age advances the hair becomes gray. This is a natural and physiological process; but it may be hastened by severe trouble or other causes. In many cases the premature blanching of the hair is hereditary. When the change is taking place party-coloured hairs may be frequently found; of these it is the basal portion which is white, while the terminal part retains its colour. Brown-Séquard made some interesting experiments on his own beard whilst it was turning gray. He marked certain of the coloured hairs, and kept a constant watch on them. He states that in some cases an entire hair would turn gray in the course of a night. Two factors would seem to be at work in producing this condition of hair—viz. a loss of the power to produce pigment, and an increase of air in the shaft of the hair. Sometimes the change occurs rapidly—in the course, perhaps, of a few hours. Well-authenticated cases of this are on record. It is said that the auburn hair of Marie Antoinette turned gray in a single night. Surgeon Parry asserts that he actually saw the jet-black hair of a rebel sepoy whilst under examination and the fear of a horrible death turn gray in the course of half an hour. Baron Alphonse de Rothschild during the Commune is another instance. It is difficult to give any reasonable explanation of these sudden cases of hair-blanching.

The hair is regarded by anthropologists as being of high importance as a race character. Although there is no one special colour of hair peculiar to any one race, this character must not be disregarded. In our own country we may see every hue from the fairest flaxen to the blackest jet. Without doubt this points to a diversity of origin. Independently of colour, however, there are characters present in the hair which separate many of the races of man widely from each other. In the American Indians, Chinese, Japanese, and natives of High Asia the hair is long, straight, and harsh like a horse's mane. Amongst the negroes, Hottentots, and Papuans it is crisp and woolly. Between these extremes we may place the European, in whom the hair is wavy and flowing. The close curling of the negroes' hair has been shown by several observers to be largely due to the fact that the hair-follicles are curved. A spiral twist is thus given to the hair. It has been held that the straight harsh hair of

the American Indian is circular in transverse section, that the wavy European hair is oval, and that the crisp woolly negro hair is flattened and tape-like in cross-section. There now appears to be reason to doubt this (see Waldeyer's *Atlas*).

The chief use of the hair, and particularly of the fur of various mammals which is especially developed in the winter, is to protect the body from external cold. Except on the scalp and on the throat, this cannot be considered as applying to man. What, then, are the uses of the hair on the face, and especially on the upper lip? We shall answer this question with an extract from an article 'On the Use of the Hair' in the *Lancet* for November 3, 1860: 'Mr Chadwick, who has done so much for sanitary reform, tells us that he was once very much struck by seeing some blacksmiths who wore beards, with their moustaches discoloured by a quantity of iron dust which had accumulated amongst the hairs. Turning it over in his mind, it struck him that had not the dust been so arrested by a natural respirator, it must have found its way into the lungs, where it could not have been otherwise than productive of evil consequences. He hence rightly advised that the razor should be discarded by labourers in all dusty trades—such as millers, bakers, masons, &c.; by workmen employed in grinding iron or steel; and by travellers on dusty roads. In hot, sandy countries the use of the beard is soon discovered; and travellers in Syria and Egypt find it necessary to defend their mouths against the entrance of the hot air of the desert. But not against dust alone is the facial hair a protection; it is the best barrier against cold air, biting winds, and wheezy fogs that a Northman can obtain. . . . According to Mr Chadwick, the sappers and miners of the French army, who are remarkable for the size and beauty of their beards, enjoy a special immunity against bronchial affections.' In corroboration of the last-named fact we may mention another of a still more striking character. During the long-continued search for Franklin's expedition, a transport vessel, the *North Star*, was frozen up during one of the severest arctic winters on record, in Wolstenholme Sound. The crew maintained their health perfectly during all the trials to which they were exposed. On their return to England in the early summer they shaved off the hair that had been growing around the mouth and throat for the last eight or nine months, and within a week *every man* was on the sick list with some form of bronchial or pulmonary disorder.

The short hairs scattered over the body may be regarded as being rudimentary. In other words, they are vestiges of a hairy covering which at one time did fulfil a protective and sheltering function. In the Ainos of Japan and the Todas of the Nilgherries these hairs are still retained in a high degree of development.

Cases occasionally occur where there is an abnormal abundance of hair of considerable length in women on parts where the hair is usually little more than down. A hairy woman, named Julia Pastrana, supposed to be a Mexican, was exhibited in London; her embalmed body was exhibited also in that city in 1862, and we extract the following remarks from a memoir on her in *The Lancet* for May 3 of that year: 'The ears, and all parts of the face except the eyes, were covered with hair of different lengths. The beard was tolerably thick, the hairs composing it being straight, black, and bristly, the part of it which grew on the sides of the chin hanging down like two plaits. . . . The upper portion of the back of the neck and the hinder surface of the ears were covered with hairs. On the shoulders and legs the hairs were as abundant as they are occasionally seen on very powerful men.' Dr Chowne described similar but less marked cases of hairy women in the *Lancet* for 1843; and in 1886 members of a Burmese family, whose bodies were almost entirely covered with hair, were first exhibited in London. See BEARD, WIG, BALDNESS, PLICA POLONICA, RINGWORM, SCALDHEAD, PARASITES, &c.; also Sir Erasmus Wilson, *Healthy Skin and Hair* (1845; new ed. 1886).

Hair-balls. See CONCRETIONS.

Hair-dressing. As a matter of convenience, as well as of taste and fashion, the dressing of the hair has received much attention in all civilised nations, ancient and modern. The Beard is the subject of a separate article. Amongst savages the most extraordinary diversity as to the dressing of their hair obtains; some frizzing it to the utmost extent; some fixing it in all sorts of perverse arrangements by means of frames, and some partially shaving the head. The Chinese pigtail, the American Indian scalp-lock, and the Moslem shaven head, with a small tuft left by which to be ultimately lifted into Paradise, are all well known. According to Rev. J. G. Paton, missionary (see his Life, 1889), some of the New Hebrides people have hair crisp and woolly, stuck full of feathers and shells; others have hair long and wavy, twisted into as many as 700 separate whip-cords on a single head, requiring the labour of five years to complete. Amongst modern civilised Europeans the courtiers and cavaliers of the 17th century adopted the practice of wearing those 'love-locks' which excited the ire of the Puritans. It was, however, in the management of ladies' hair that the art of the professional hair-dresser was in those times mainly exercised. In the 18th century, through the influence of French fashions, the dressing of hair, male and female, rose to a great pitch of extravagance and folly (see WIG). The hair of a lady of fashion was frizzed up in convolutions and curls, decorated with ribbons, jewels, and feathers, and filled with pomatum and powder to a degree perfectly monstrous. As women of less exalted rank slavishly attempted to follow these absurdities, the business of dressing hair was extensively followed. The cost of a full dressing being, however, too high to be lightly incurred, often one dressing was made to suffice for a week or fortnight, during which period such care was taken to preserve the greasy fabric undisturbed, that it became the frequent resort of troublesome insects. From pressure of business it frequently happened that previous to balls ladies' hair had to be dressed one or two days in advance; and to keep the head-dress uninjured the lady sat in a chair perhaps two nights instead of going to bed. A tax on Hair-powder (q.v.), along with the simplification of fashions consequent on the French Revolution, not only expelled hair-powder and perruques, but brought the profession of hair-dresser within reasonable bounds. As regards ladies' hair, fashion is constantly altering. With respect to men's hair, short cutting is now universal. Pursued as an ordinary business in England and continental countries, hair-dressing in the United States is to a large extent resigned to men of colour, and in connection with many of the hotels they are provided with work-rooms. Of the innumerable oils, essences, and pomade which are vended for the hair, on the doubtful assumption that they improve and nourish it, some are distinctly injurious.

Hair-dyes. Various means have been adopted for changing the natural colour of the hair to a more favoured one, and for hiding the approaches of age, as indicated by the presence of gray hairs. These usually consist in washing the hair with a

solution of some metallic salt known to have the effect of darkening its colour, such as salts of silver, mercury, lead, and bismuth. Pyrogallic acid is also employed to give a brown tint, while a solution of peroxide of hydrogen in water imparts a fine golden colour. The most perfect mode of dyeing the hair black is that of previously preparing it by a complete soaking with a solution of sulphide of potassium; the strength of this solution must depend on the depth of tint intended to be given; the stronger the solution the darker the colour will be. When thoroughly wetted, the hair is allowed to dry partially; and whilst still damp it is to be saturated with a solution of nitrate of silver, of a strength proportionate to the depth of colour desired. This makes a very permanent dye, which only requires renewing where the new growth of hair becomes conspicuous. The fashion of dyeing the hair is very ancient, and belongs as much to savage as to civilised nations; but in the case of the former vegetable dyes have been chiefly used. In China and other eastern countries the juice of the petals of *Hibiscus Trionum*, the Bladder-Ketmia, and probably other species of Hibiscus, is in general use.

The detection of stained hair is sometimes an object of medico-legal investigation. Lead may be detected by boiling the hair in dilute nitric acid, and then applying the tests for Lead (q.v.) to the acid solution; while the presence of silver may be shown by digesting the hair in dilute hydrochloric acid or chlorine water, when the resulting chloride of silver may be dissolved out with a solution of ammonia, and submitted to the ordinary tests for Silver (q.v.).

Hair-eel, the form into which horse-hairs left to soak in running water are preposterously assumed by many to develop. The hair-eel or horse-hair worm is really a Nematode (q.v.); see also Eel, Thread Worms.

Hair Grass (*Aira*), a genus of grasses, having delicately panicled inflorescences, bearing spikelets with two unequal glumes, and two perfect flowers, each with two thin membranous bracts, of which the outer is generally awned. The species are natives of temperate and cold climates. Five species are natives of Britain, and are chiefly found in moors, sandy pastures, and other situations where the soil is unfertile. The Tufted Hair Grass, or Turfy Hair Grass (*A. cæspitosa*), common in better pastures and meadows, is a beautiful grass when in flower, but forms coarse tufts of very rough leaves, which are usually rejected by cattle. It attains a height of 2 to 4 feet, and is sometimes used for thatching ricks of hay or corn, and in some places for making mats. It grows luxuriantly in moist situations, and indicates a badly drained soil. It is occasionally tolerated, in order to add to the bulk of *Bog Hay* in moorish grounds, but is carefully extirpated wherever agricultural improvement takes place. This grass is, however, sometimes sown to form cover for game, particularly hares; and in marshy situations for snipes and wild fowl. It is the *readhstra* of the Scotch.

Hair Manufactures. In this article the various kinds of hair (except wool) used in manufactures are noticed, together with the different fabrics or articles made from them. Remarks on a few of these will be found under Alpaca, Bristles, Brush, and Fibrous Substances. For sheep's wool, which like fur is modified hair, and the similar animal fibres mohair and alpaca, see Woollen Manufactures. Fur-covered skins used for articles of dress in their natural condition, with just sufficient treatment to preserve them, are described under Fur; while the employment of wool, fur, and hair in the manufacture of felted goods is noticed under the headings Felt and Hat.

Human Hair. The trade in Britain in this is considerable, supplies of it being chiefly obtained from continental Europe, India, and China. The hair shipped from Asiatic countries is coarse, that from Germany and Scandinavia is light-coloured, and that collected in Italy and southern France is dark. In former years an occasional supply of good quality was got from Ireland. Hair 8 inches long is worth about 1s. per ounce, while such as extends to the length of 3 feet sometimes reaches as high a price as 30s. per ounce. Certain colours, such as pure golden, are of greater value than more common kinds, and hair from the living subject is much better than dead hair. Human hair is worked up into watch-guards, brooches, bracelets, and other personal ornaments, the patterns of which are often very beautiful. In the article Wig this and other imitations in hair of the natural covering of the head are noticed.

Horse hair. The comparatively small quantity of this hair obtained in England is got from the combings of tails and manes, but it is of excellent quality. Horse-hair is imported from Russia, Germany, Belgium, South America, and Australia; the imports for the five years ending 1888 averaging nearly 20,000 cwt. annually. The United States import hair to the value of from 2¼ to 2½ million dollars annually; exporting a value of from 350,000 to 420,000 dollars. Hair combed from the tails of horses is the most valuable, that from the mane being of inferior quality. The former is designated 'hard,' and the latter 'soft,' while the hair is further distinguished by the terms 'live' and 'dead,' according as it has been taken from the animal before or after death. 'Live' hair commands the highest price. White is the most valuable kind as regards colour, as it is suitable for dyeing bright tints, and the best hair is obtained from wild horses.

Horse-hair undergoes three sortings—viz. into sorts according to length, into different colours, and into various qualities. After this the hair is washed generally in warm soap baths and in water slightly heated, to which lime or potash has been added. The hair, except the white sort, which is to be bleached, is, after cleaning passed through a dye bath in which logwood is the chief ingredient. Short hair being used for stuffing in upholstery work, and long hair chiefly for the manufacture of haircloth, the two kinds after the above treatment undergo different processes.

Short horse-hair, although best for the purpose when used alone, is nevertheless mixed with cow and pig hair for stuffing chairs, sofas, and the like. Different blends of these are made, and the three kinds thoroughly incorporated by suitable machines, after which the mixture is beaten and screened to clear it of dust. Then follows the 'curling' process, by which the hair is first spun into ropes, which are next twisted into much shorter lengths, and by a third operation further twisted till they get into a convolute shape. The curl thus given requires to be fixed by placing the hair in cold water for several hours, and afterwards in an oven, where it is kept for some time at a high temperature. This baking also destroys the eggs of obnoxious insects. The hair in this rope form requires to be teased up for use. For inferior stuffing vegetable fibres are now mixed with hair.

Haircloth.—Long horse-hair is combed on steel combs, and separated into different lengths and thicknesses, about 3 feet being the longest size. The chief application of long hair is in the manufacture of haircloth, which is generally though not always black. Even when naturally black the hair is dyed to give it a uniform colour. White hair is

bleached and dyed different colours. The length of the hair determines the width of the cloth, since the weft is formed of single hairs. Strong linen or cotton twist commonly form the warp. Up to the middle of the 19th century a child at one side of a handloom supplied a hair to the weaver for each throw of the shuttle, to which the hair was hooked. A subsequent invention made it practicable to dispense with the child or server, the weaver by means of a treadle working both the hook-shuttle for drawing through, and the batten for driving home, the weft hairs; and at the same time supplying these hairs with his or her own hands.

The power-loom, invented by Mr Isaac Lindsley, of Pawtucket, Rhode Island, was the first successful attempt to supersede the hand-loom in the weaving of haircloth. In it the end of an arm or rod, made to operate like a finger and thumb, grasps the hairs as they are presented to it by a picker which takes up a single hair from a bunch, and this hair is then carried by the rod through the shed of the warp. This loom has been extensively used in the manufacture of haircloth. In some more recent ones, however, the working parts have been simplified, and an important arrangement introduced by which the thin and the thick ends of the hair are taken up by the picker alternately.

Haircloth is so woven that only the hair portion is seen on the surface, the linen or cotton warp being hidden. Most of what is made in England is plain, but some haircloth damasks, both black and coloured, are woven; so also are striped pieces of various colours. These ornamental kinds, which are well suited for elegant furniture in tropical regions, are largely made on the Continent. In some special kinds of fabric both warp and weft are of horse-hair. Among these are sieve-bottoms for cooks, chemists, and powder manufacturers. Other examples are press-cloths used in making cider, and tailors' ironing cloths. Horse-hair is worked up into ornamental cord-like or braid-like forms (crinoline) for ladies' bonnets, into borders and cords for carriages, into material for cigar-cases and similar articles, and into fishing-lines.

'Brussels' carpet of horse-hair was introduced by Mr E. Webb of Worcester. Several kinds of carpet partly or wholly composed of this material are now made. In these tissues the hair is not woven in the same way as it is in ordinary haircloth, but as a yarn for which short hair, sometimes mixed with the hair of other animals, is generally used. The material is carded, spun, and twisted. Some carpets have both warp and weft of hair; others have only a plain warp of hair with a weft of jute; others again have a backing and weft of hemp, jute, or cotton, and the pile warp of horse-hair. These carpets are extremely durable, and therefore well suited for offices and other rooms in which there is much traffic.

Cow-hair is consumed in considerable quantities by plasterers to bind the plaster put on the internal walls of houses. As already stated, it is mixed with horse-hair for stuffing purposes, and with wool for common blankets, carpets, rugs, and other articles. Cow-hair is also used in the manufacture of roofing and other felts. This kind of hair is obtained in considerable quantities from tanneries. The imports of it in 1888 amounted to 95,000 cwt.

Camel-hair is obtained from the legs, the neck, and the humps of both species of Camel (q.v.). The hair of the Arabian camel is fine and light-coloured; that from the Bactrian camel is coarser, and of a darker shade. It, however, varies in degree of fineness according to the age of the animals, young ones yielding the finest kind. In Tartary, Persia, Arabia, and other eastern countries camel-hair is woven into a soft, warm, and durable cloth for personal wear. It is also made into carpets, tent-coverings, and other articles. Since 1860 a good deal of this hair has been sent to Europe and America for weaving into carpets and for mixing with wool; in the case of the finer kinds, for warm clothing. The so-called camel-hair brushes are made from the tail of the sable or of some kinds of squirrel.

Goat-hair.—The hair of the common goat is used for the manufacture of cheap carpets and for other purposes, but that of the Angora or mohair goat is now a very important material in our textile industries. This mohair, as it is called, is described under WOOLLEN MANUFACTURES, and the fine wool forming part of the fleece of the Cashmere or shawl goat is noticed under CASHMERE GOAT, SHAWL.

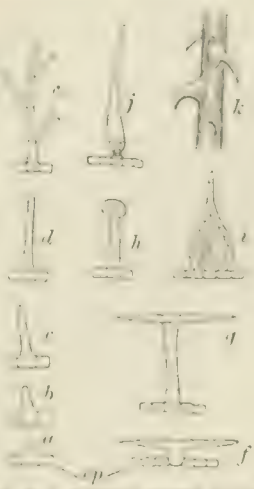
Pig-hair or Bristles. Some pig hair is mixed with other kinds for stuffing. The principal use of this material, however, is for making brushes. See BRISTLES and BRUSHES.

Elephant's Hair.—The strong hair of the elephant's tail is occasionally turned to some use. For example, a native bracelet is employed by some of the tribes in Nyassaland, which consists simply of two such hairs plaited.

Hair-powder, a pure white powder, made from pulverised starch, scented with violet or some other perfume, and at one time, especially in the 17th and 18th centuries, largely used for powdering over the head. The fashion became universal among the higher and middle classes, and by ladies as well as gentlemen. To make the powder hold, the hair was usually greased with pomade, and accordingly the fashion was extremely troublesome. An act of parliament fixed that the fine dust of which the powder was composed should be made from starch alone; and we learn from the *Gentleman's Magazine*, that on November 20, 1746, fifty-one barbers were convicted before the Commissioners of Excise at London, and fined £20 each, for having in their keeping hair-powder not made of starch, contrary to act of parliament. In 1795 a tax of a guinea (afterwards £1, 3s. 6d.) was put on the use of hair-powder, and at one time yielded £20,000 per annum, but it had the effect of causing hair-powder to fall into general disuse. The French Revolution, which overturned so many institutions, contributed also to the people of Europe returning to natural and unpowdered hair. At the present day powder continues to be used by some of the footmen of the nobility and higher ranks as part of their livery. The tax on hair-powder was repealed in 1869. At the time of its abolition it was paid by about 800 persons, and yielded a revenue of about £1000 a year.

Hairs of Plants are outgrowths of epidermal cells, which assume various forms. They may remain unicellular, resembling simple tubes, or become multicellular by division of the originally simple cell. They develop on almost any part of the surface of plants; and there are few plants that are entirely without them. A plant may have only one form of hair; but most plants have several forms. Similar kinds of hairs are often characteristic of plants belonging to the same order—e.g. the glandular hairs of the sun-dew (Drosera) order, the stinging hairs of the nettle (Urtica) order, and the scaly hairs of ferns. Root-hairs (see ROOT) are among the simplest in form; they are always unicellular tubes which absorb water and certain minerals essential for the life of the plant. The aerial organs of plants develop hairs which serve to protect them from cold, or injury from other sources—e.g. many winter buds have hairy scale leaves which often, with a gummy secretion, keep out moisture, and thus protect the tender tissues from injury by frost. Many leaves also are protected from excessive radiation by the

growth of hairs. The common form of glandular hair is that with a swollen tip which secretes oily or resinous, often strongly smelling, matters which may be regarded as waste-products that have become adapted to the attraction and capture of insects: see INSECTIVOROUS PLANTS. Some glandular hairs have the glands within their bases. In the orders Compositæ and Valerianeæ hairs form on the fruit an organ of flight (*pappus*), by means of which the wind is enabled to carry the seeds, and thus secure their wide distribution. When hairs become stiff, generally by impregnation with silica, they form bristles; and when they become woody and hard they form prickles, as in the bramble and rose. Hairs may also grow internally in large intercellular spaces, but these occur only in a few plants.



[illegible] different forms in the leaf-epidermis of [illegible]: *d*, [illegible]; *e*, [illegible]; *f*, stinging hair with drop of poison at the top (all the above are in section); *g*, prickle-bearing; *h*, epidermis.

Hair-tail (*Trichiurus*), a genus of acanthopterous fishes belonging to the tropical marine fauna, and found generally near land. The body is long, scaleless, greatly compressed, ribbon-shaped, and ends in a long, whip-like tail. The cleft of the mouth is deep, and there are strong teeth on the jaws and the palate. The dorsal fin extends along the whole of the back and is spiny throughout; the ventral fins, when present, are in the form of a pair of scales; the anal spines are small, and are sometimes concealed beneath the skin. Six species are known. Some of them attain a length of four feet. One species, the Silvery Hair-tail or Ribbonfish (*T. lepturus*), is found in the Atlantic Ocean, on the east coast of North America, from Cape Cod to Florida and the West Indies. Wanderers are caught off the British and Irish and more rarely the French coasts. The other species are most common in the seas of India, the Malay Archipelago, and China. As food they are held in various estimation in different places.

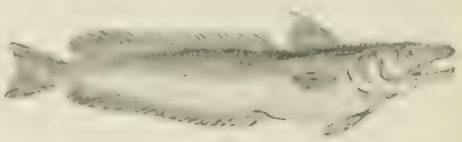
Haiti. See HAYTI.

Haje. See COBRA.

Hajipur, a town of Bengal, on the Gandak, just above its confluence with the Ganges opposite Patna. It has a large river trade. Pop. 25,078.

Hajj, or HADJ, from an Arabic word meaning 'pilgrimage,' emphatically the pilgrimage to the Kaaba (q.v.) or black stone in the great mosque at Mecca, which every Mohammedan whose means and health permit is bound to perform once at least in his life (see MECCA). The hajj once performed, the pilgrim never omits to prefix the proud title of Hajji to his name. Those who are incapacitated through bodily infirmity from performing the holy journey themselves may send a substitute, who acts as their representative in almost every respect, but this substitute has no share whatever in the merits and rewards belonging to the Hajj. Members of the Greek and Armenian churches who perform the pilgrimage to Jerusalem are likewise known as Hajji.

Hake (*Merluccius*), a genus of fishes of the cod family (Gadidæ), having a flattened head, an elongated body, two dorsal fins, of which the first is short, and the second very long, one very long anal fin, and the mouth destitute of barbels. One species, the Common Hake (*M. vulgaris*), is found in the British seas, in those of the north of Europe, and in the Mediterranean. It is sometimes 3 or 4 feet in length; and is of a whitish colour, grayish on the back. It is a very voracious fish, devouring great numbers of herrings and pilchards; hence it



Hake (*Merluccius vulgaris*).

is frequently called the *Herring Hake*. It is a coarse fish, its flesh white and flaky; but it is important as an article of human food and of commerce, being salted and dried in the same manner as cod and ling, in common with which it receives in this state the name of *stock-fish*. It is generally taken by lines, like cod and ling. In the spawning season, when it keeps near the bottom, it is sometimes caught by trawl nets. One other species is known, *M. gayi*, which is common in the Strait of Magellan and on the coasts of Chili, and also occurs in New Zealand.

Hakim Ben Allah. See MOKANNA.

Hakluyt, or HACKLUYT, RICHARD, an English writer on geography, belonged to a Herefordshire family, and was born in 1553. While at Westminster School he eagerly perused narratives of voyages and travels, and continued this course at Christ Church, Oxford, whither he proceeded in 1570. Being appointed lecturer on geography or cosmography in that university, he introduced the use of globes and other geographical appliances into English schools. The publication of *Divers Voyages touching the Discovery of America* (1582) seems to have been mainly instrumental in procuring for him two years later the appointment of chaplain to the English embassy to Paris. There he wrote *Discourse concerning Western Discoveries* (1584), and had Laudonnière's manuscript narrative of the discovery of Florida printed, first in French and afterwards in English, at his own expense. On his return to England in 1588, with the assistance of Sir Walter Raleigh, he began to collect materials for the history of the discoveries made by his countrymen. He published the fruits of his researches, in notices of more than 200 voyages, under the title *Principal Navigations, Voyages, Traffiques, and Discoveries of the English Nation* (3 vols. 1598–1600; new ed. 5 vols. 1809–12). Government rewarded him by bestowing upon him a prebend in Westminster Abbey. *A Selection of Curious, Rare, and Early Voyages and Histories of Interesting Discoveries*, &c., chiefly published by Hakluyt, or at his suggestion, but not included in his compilation, forms (1812) a supplement to the above work. He also edited English translations of Galvano's *Discoveries of the World* (1601) and Fernando de Soto's *Virginia richly Valued* (1609). He died in 1616, and was buried in Westminster Abbey. Hakluyt's unpublished manuscripts were made use of by Purchas in his *Pilgrims* (1625–26). The *Hakluyt Society* was instituted in 1846 for the purpose of publishing all the histories of the earlier voyages and travels.

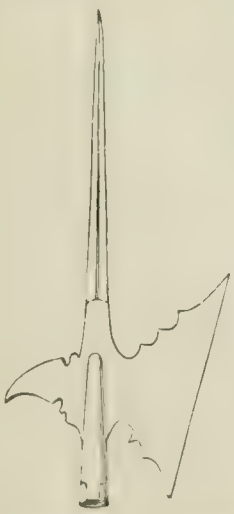
Hakodate, the chief port of Yezo in Japan, situated on a peninsula in the Strait of Tsugaru. The town is built partly on the inner slope of the Gibraltar-like hill (1200 feet) which dominates the strait, partly on the low sandy peninsula connecting the hill with the main island. The climate is severe. Hakodate, which has a magnificent harbour, is (since 1859) one of the open ports of Japan, and carries on a brisk export trade in seaweed, sulphur, bêche de mer, salted salmon, matches, &c. The annual value of exports is towards £200,000; that of imports is trifling. Pop. (1893) 63,916.

Hal, a town in South Brabant, 9 miles by rail SSW. from Brussels. The church of St Mary (1341–1409) is much resorted to by pilgrims on account of a black miracle-working wooden image of the Virgin, which during a bombardment in 1580 caught thirty-three cannon-balls in her lap—they lie piled up in the tower. Pop. 9739.

Halacha. See EXEGESIS, TALMUD.

Halas, a town of Hungary, in the district of Little Cumania, 82 miles by rail SSE. of Budapest. Pop. 15,039.

Halberstadt, a quaint old town of Prussian Saxony, situated in a fertile plain extending from the north foot of the Harz Mountains, 25 miles SW. of Magdeburg. The cathedral, containing fine painted glass, and valuable antiquities and objects of art, although restored in 1850–71, is the most notable building in the town. It was erected in the 13th and 14th centuries in the Pointed style. Other buildings of interest are the church of Our Lady (1146), with antique reliefs and wall-paintings; the town-house (1360–81), before which stands a Roland pillar; the wine-cellar beneath the town-house; and the Peterhof, formerly the residence of the bishops. The chief industries of the town are gloves, cigars, machines, sugar, leather, paper, spirits, &c.; and there are also large workshops for railway repairs. Halberstadt dates from 820, the year in which the see was transplanted from Osterwieck to the site of the town of Halberstadt. It received town rights in 998; was twice burned down in the 12th century; and was held alternately by the Swedes and Imperialists during the Thirty Years' War. In 1648 it was given to Brandenburg. Pop. (1875) 27,800; (1890) 36,786. See Zschiesche, *Halberstadt sonst und jetzt* (1882).



Ancient Halbert-head.

Halbert, or HALBARD, a weapon which consisted of a strong wooden shaft about 6 feet in length, surmounted by an instrument resembling an axe, balanced on the opposite side by a hook or pick, whilst the shaft was continued in a sharp pike-head. The weapon was much used in Germany, Switzerland, and France. In England it was a common arm from the reign of Henry VII. to that of George III. Now it is rarely seen except as borne by yeomen of the guard and others on certain ceremonial occasions. A variety of the same weapon may be recognised in the Scottish Lochaber Axe (q.v.).

Halcyon Days, a name given by the ancients to the seven days which precede and the seven which follow the shortest day of the year, on account of a fable that during this time, while the halcyon bird or Kingfisher (q.v.) was brooding, there always prevailed calms at sea. From this the phrase 'halcyon days' has come to signify times of happiness and tranquillity.

Haldane, ROBERT, was born in London, February 28, 1764, and was educated at the grammar-school of Dundee and the university of Edinburgh. In 1780 he joined the *Monarch*, his uncle Viscount Duncan's ship, afterwards saw some service under Admiral Jervis, and was present at the relief of Gibraltar, but left the navy at the peace of 1783 to settle on his estate near Stirling. The French Revolution fired him with new hopes for the regeneration of man, but ere long a profound spiritual change turned the energies of his life into completely new channels. His vast project for a great mission in Bengal, at his own expense, was frustrated by the East India Company's refusal of their sanction; but by his 'Society for the Propagation of the Gospel at Home' he built so many 'tabernacles' and supported so many itinerant preachers that in twelve years he had expended more than £70,000. In the year 1817 he lectured to theological students at Geneva and Montauban, and returned to Scotland in 1819, taking an active interest thereafter in all religious questions, as the Apocrypha and Sabbath controversies. He died 12th December 1842. His best-known books are *Evidences and Authority of Divine Revelation* (1816), *On the Inspiration of Scripture* (1828), and *Exposition of the Epistle to the Romans* (1835). JAMES ALEXANDER, brother of the preceding, was born at Dundee, July 14, 1768, and was educated at the High School and university of Edinburgh. At sixteen he entered the navy, and served for nine years, after which he abruptly abandoned the service, although in the meantime he had been appointed to the command of a vessel. A study of the Bible had led him to the same conclusions in religion as his elder brother. Soon afterwards he made the acquaintance of the famous Simeon of Cambridge, and with him traversed Scotland on an evangelistic tour. His later missionary journeyings brought him into collision with the Church of Scotland, and at length in 1799 he was ordained the independent pastor of a church in Edinburgh, in which he preached gratuitously for fifty years, and which in 1808 he led into the Baptist fold. He died 8th February 1851. His pamphlets were widely read in their day by those within the range of his influence. Two late books were his *Doctrine of the Atonement* (1845) and his *Exposition of the Epistle to the Galatians* (1848). See *Memoirs of R. and J. A. Haldane*, by Alexander Haldane (1852).

Hale, JOHN PARKER, an American statesman, was born at Rochester, New Hampshire, in 1806, and was United States attorney for his state in 1834–41. Returned to congress in 1842, as a Democrat, his name was afterwards removed from the party ticket because he refused to support the annexation of Texas. The struggle that followed ended in a victory for the anti-slavery party, and in 1847 Hale was elected to the United States senate, where he served for sixteen years. He was the Free-soil candidate for the presidency in 1852, but received under 5 per cent. of the total popular vote. He was minister to Spain from 1865 to 1869, and died 19th November 1873.

Hale, SIR MATTHEW, Lord Chief-justice of England, was born 1st November 1609 at Alderley, Gloucestershire. Intended for the church, he was sent to Oxford University in his sixteenth year. But suddenly he abandoned his studious habits, and, joining a company of strolling-players, gave way to a good deal of dissipation. He was on the

point of becoming a soldier when Serjeant Glanville induced him to adopt the legal profession. Accordingly in 1628 Hale entered the Society of Lincoln's Inn, and resuming his habits of persevering study was in due course called to the bar 1637. He soon acquired a considerable practice. In the quarrel between king and parliament Hale refrained from identifying himself with either side. When, however, parliament got the upper hand, he signed the Solemn League and Covenant, sat in the Assembly of Divines at Westminster, tried to bring about a settlement between the king and parliament, and ultimately, taking his engagement to the Commonwealth, was made a judge under Cromwell in 1653. He acted as a *puisne* judge of the Common Pleas till Cromwell's death, but refused to have his commission renewed by Richard Cromwell. After the Restoration he was made Chief baron of the Court of Exchequer, and eleven years later was transferred to the Chief justiceship of the Court of King's Bench. As a judge he was acute, learned, and sensible, and set his face against bribery, one of the vices of the age. He was a pious man and a friend of Richard Baxter, but, like Baxter, was not able to rise superior to the belief in witchcraft. He wrote numerous works, as *History of the Pleas of the Crown* (1739), *History of the Common Law of England* (1713), and various *Moral and Religious Works* (ed. by Thirlwall, 1805); and he bequeathed several valuable legal MSS. to Lincoln's Inn. He resigned his office from ill-health in February 1676, and died on Christmas day of that year. See Lives by Burnet (1682), Williams (1835), Roscoe (1838), and Campbell (1849).

Hale, NATHAN, an American soldier, who was born at Coventry, Connecticut, 6th June 1755, rose to the rank of captain in the Continental army, and, having volunteered to penetrate the British lines and procure intelligence for Washington, was detected, and executed as a spy in New York city, 22d September 1776. See Lossing, *The Two Spies, Nathan Hale and John Andre* (New York, 1886).—His grand nephew, EDWARD EVERETT HALE, was born in Boston, Massachusetts, 3d April 1822, graduated at Harvard in 1839, and was admitted to the Congregational ministry in 1842. In 1856 he was called to the South Congregational (Unitarian) Church in Boston, and in 1879 he received his doctorate from Harvard. His influence in philanthropic movements has been widespread. His book *Ten Times One is Ten* (Boston, 1870) originated in America a numerous series of 'Lend a Hand' clubs, sometimes under other names, and with offshoots in Europe, Asia, Africa, and the Pacific Islands; a recent development in the United States is the society of 'The King's Daughters.' The motto of these clubs is 'Look up and not down; look forward and not back; look out and not in; and lend a hand.' Dr Hale has edited several religious and other journals, as well as Lingard's *History of England*, and original documents (from the British state papers and the British Museum) bearing on the founding of Virginia. His published books, mostly stories, number nearly fifty.

Hale, SARAH JOSEPHA, author of *Mary's Lamb*, was born at Newport, New Hampshire, October 24, 1788. On the death of her husband, David Hale, in 1822, she devoted herself to authorship, and became in 1828 editor of the *Ladies' Magazine*, which she continued to conduct after it had, in 1837, become united with *Godey's Lady's Book*, nor did she retire from her editorial work until 1877. She was instrumental in procuring the employment of lady medical missionaries, in completing the Bunker Hill monument, and in securing that Thanksgiving Day should be simultaneously observed in all the states. She published nearly twenty works, including poems, cookery books, books of poetical extracts, and novels. Her most important work is *Woman's Record, or Sketches of Distinguished Women* (3d ed. 1869). She died 30th April 1879.—Her son, HORATIO (1817-96), in 1837 graduated at Harvard, and was appointed ethnologist to the United States Pacific exploring expedition. He prepared the valuable expedition report on *Ethnography and Philology* (1846), and has published numerous memoirs and works on kindred subjects, including *Indian Migrations as evidenced by Language* (1883), *The Iroquois Book of Rites* (1883), a *Report on the Blackfoot Tribes*, presented to the British Association in 1885, and his introductory address, delivered as president of the Anthropological Section of the American Association in 1886, on *The Origin of Languages and the Antiquity of Speaking Man*.

Halepa, a suburb of Canea (q.v.), where in 1869 the Turks made concessions to the Cretans.

Hales. See ALEXANDER OF HALES.

Hales, JOHN, the 'Ever-memorable,' was born at Bath in 1584, and was educated in 'grammar learning' in his native city. At thirteen he entered Corpus Christi College, Oxford, took his degree in July 1603, and obtained a fellowship at Merton College in 1605 as 'a person of learning above his age and standing.' Wood tells us of his extraordinary subtlety in philosophical disputation, of his eloquence, and of his unusual knowledge of the Greek tongue, which contributed greatly to Sir Henry Savile's edition of St Chrysostom, and procured for himself in 1612 the chair of Greek in his university. Next year he delivered the funeral oration of Sir Thomas Bodley, and was admitted a Fellow of Eton. In 1618 he went to the Hague as chaplain to the ambassador, Sir Dudley Carleton, for whom he made a report of the proceedings at the famous synod of Dort, in a very interesting series of letters. Here the passion and contentious zeal of extreme orthodoxy seem to have convinced him that neither side possessed the monopoly of truth, and indeed that it is a hopeless attempt to express spiritual truth within precise dogmatic definitions. According to his friend Farindon, 'there he bid John Calvin good-night, as he often told.' Early in 1619 he returned to Eton to devote himself to continuous study, varied only by a journey to London once a year. Yet he was no melancholy recluse, but delighted in the conversation of such friends as Chillingworth, Lord Falkland, Savile, and Sir Henry Wotton, as well as Ben Jonson, Suckling, and other London wits. His too liberal *Tract concerning Schism and Schismatics* brought him under the displeasure of Laud, who was, however, satisfied after a personal conference and an apologetic letter, and appointed him to a canonry at Windsor, the only preferment Hales could ever be induced to accept. No doubt he allowed himself to be persuaded, because he loved peace better than argument; and Peter Heylin's account of how Hales told him that Laud's logic had 'ferreted him from one hole to another' need not be taken too literally, being, as Hallam says, ludicrous, considering the relative abilities of the two men. The Puritan supremacy deprived him of his office, and reduced him to great want, which Andrew Marvell said well was 'not one of the least ignominies of that age.' He was forced to dispose of his fine collection of books, which must have been the keenest trial to his scholar's heart. He died at Eton, 19th May 1656.

Hales is a rare example of a profound student without pedantry, a ripe theologian with an altogether untheological clearness of mind and direct-

ness of phrase. His conviction that dogmatic differences do not really affect religion, and his zeal for freedom of spirit rather than rigidity of form, belong not to his own time, but were qualities well becoming the dear friend of Falkland and Chillingworth. The genial sweetness of his temper and the humble modesty of his bearing fitted well with a singularly devout but unobtrusive piety, and help to account for the unwonted glow of warmth in the accounts of him by Clarendon, Pearson, Marvell, and Stillingfleet alike. Aubrey's false imputation of Socinianism has done much wrong to the memory of one of the most loyal although enlightened sons of the Church of England; but we have to thank his rambling pen for a glimpse of the gentle and cheerful little scholar not a year before his death, 'in a kind of violet-coloured cloth gown with buttons and loops,' the *Imitation* in his hand. His picture is one of the finest in the gallery of Clarendon, whose own words best help to explain the large tolerance of his temper and his broad conception of Christianity: 'He had, whether from his natural temper and constitution, or from his long retirement from all crowds, or from his profound judgment and discerning spirit, contracted some opinions which were not received, nor by him published, except in private discourses, and then rather upon occasion of dispute than of positive opinion; and he would often say his opinions, he was sure, did him no harm, but he was far from being confident that they might not do others harm, who entertained them, and might entertain other results from them than he did; and therefore he was very reserved in communicating what he thought himself in those points in which he differed from what was received.

'Nothing troubled him more than the brawls which were grown from religion; and he therefore exceedingly detested the tyranny of the Church of Rome, more for their imposing uncharitably upon the consciences of other men than for the errors in their own opinions; and would often say that he would renounce the religion of the Church of England to-morrow if it obliged him to believe that any other Christians should be damned; and that nobody would conclude another man to be damned who did not wish him so.'

His friend Anthony Farindon (1598–1658) undertook to collect his writings, and write a memoir, but died before his task was completed. In a letter to his publisher he says, 'I am like Mr Hales in this, which was one of his defects, not to pen anything till I must needs.' And indeed all Hales's writings, valuable as they are, are occasional and unsystematic in form. The *Golden Remains of the Ever-memorable Mr John Hales of Eton College* were at length published in 1659 under the care of Pearson, who prefixed not a Life but an Epistle to the Reader, containing a most eulogistic character of his author. This edition was reprinted in 1673 and 1688, and in 1677 a new volume gave several additional tracts. The best edition is that issued in three small volumes by the Foulis Press at Glasgow in 1765, edited by Sir David Dalrymple, afterwards a Scottish judge with the title of Lord Hailes. See chap. 4, vol. i., of Tulloch's *Rational Theology in England in the 17th Century* (1872).

Hales, STEPHEN, natural philosopher, was born at Beckesbourn, Kent, 7th September 1677. He entered Bene't (now Corpus Christi) College, Cambridge, in 1696, was elected Fellow in 1702, and having taken holy orders was presented about 1710 to the perpetual curacy of Teddington, in Middlesex, where he died, 4th January 1761. His first important publication was *Vegetable Staticks, or Experiments on the Sap of Vegetables* (1727), which may be regarded as the starting-point of our true knowledge of vegetable physiology. In *Hæmastaticks* (1733), a second part of this work treating of the circulation of the blood, Hales gives results obtained by experimental methods of investigation like those now in use in studying physiology. Besides other independent works, including *The Means of Dissolving the Stone in the Bladder*, he contributed numerous memoirs to the *Philosophical Transactions* on Ventilation, on Electricity, on the Analysis of Air, &c. His ventilating-machines were introduced into the London prisons. His improvements in the mode of collecting gases did much to facilitate the subsequent labours of Black, Priestley, and Lavoisier. He also invented machines for distilling sea-water, preserving meat, &c.

Halesowen, a market-town of Worcestershire, on the river Stour, 7½ miles WSW. of Birmingham. Its people are nail-makers and manufacturers of small ironwares. One mile to the south-east lie the ruins of the Premonstratensian abbey founded by King John. Shenstone (1714–63), a native of the place, carried on his landscape-gardening at the Leasowes, a mile distant from Halesowen. His tomb is in the church. Pop. 3338.

Halévy, JACQUES FRANÇOIS FROMENTAL ÉLIE, composer, was born of Jewish family at Paris, 27th May 1799. He studied at the Conservatoire there under Berton and Cherubini, afterwards at Rome, devoting himself especially to the old church music of Italy, and on his return strove in vain to put on the boards his operas, *La Bohémienne* and *Pygmalion*. His next operas, *L'Artisan* (1827) and *Le Roi et le Bâtelier* (1828), were failures, but *Clari* (1828), in which Malibran took the chief rôle, and the comic opera, *Le Dilettante d'Avignon* (1829), were successes, and ere long Halévy found himself the composer of the day, and his masterpiece, *La Juive* (1835), carried his name over Europe. His next best work is the comic opera, *L'Éclair* (1835). Later works represented with greater or less success are *Guido et Ginevra*, *Les Treize*, *Le Drapier*, *Le Guitarrero*, *La Reine de Chypre*, *Les Mousquetaires de la Reine*, *Le Val d'Andorre*, *La Tempête*, and *Dame de Pique*, the last two with the libretto by Scribe. Halévy died at Nice, 17th March 1862. Among his pupils were Gounod, Victor Massé, Bazin, and George Bizet, who married his daughter. He worthily carried on the succession of the great school of French opera, midway between Cherubini and Meyerbeer—sharing the perfect mastery of resource of the former and the tendency of the latter to subordinate everything to effect, and instinctively avoiding the commonplace or vulgar. Admitted to the Academy of Fine Arts in 1846, he became perpetual secretary in 1854. His *éloges* were collected as *Souvenirs et Portraits* (1861), and *Derniers Souvenirs et Portraits* (1863). His Life was written by his brother Léon (2d ed. 1863) and by Pougin (1865).

LÉON HALÉVY, brother of the foregoing, was born at Paris, 14th January 1802, studied law, filled a chair in the Polytechnic School, and afterwards, from 1837 to 1853, a post in the Ministry of Instruction, which he resigned to give himself entirely to literature. He died at St Germain-en-Laye, 3d September 1883. He wrote the introduction to Saint-Simon's *Opinions littéraires, philosophiques, et industrielles* (1825), and afterwards, on his own account, histories, poetry, fables, novels, dramatic poems, and translations of *Macbeth*, *Clavigo*, &c. His best books are *Résumé de l'Histoire des Juifs* (1827–28), *Poésies Européennes* (1837), and *La Grèce Tragique* (1845–61).

LUDOVIC HALÉVY, son of Léon, was born at Paris, 1st January 1834, and in 1861 became secretary to the Corps Législatif. He first made himself known as the writer of the librettos to Offenbach's burlesques (partly in collaboration with Meilhac):

Orphée aux Enfers (1861), *La belle Hélène* (1865), *La Vie Parisienne* (1866), *La Grande-duchesse de Gerolstein* (1867), *Les Brigands* (1870). He wrote besides a large number of vaudevilles and comedies, among them *La Parichole* (1868), *Frontin* (1869), *Tricoche et Cacolet* (1872), *Le Mari de la Débutante* (1878), and *La petite Mère* (1880). His *Madame et Monsieur Cardinal* (1873) and *Les petits Cardinal* (1880) are delightfully humorous sketches of Parisian theatrical life; his *L'Invasion* (1872) was a collection of personal recollections of the war. In 1882 he startled the world with his charming idyllic story *L'Abbé Constantin*, which has been well followed, but not in the same vein, by *Criquette* (1883) and *Deux Mariages* (1883). Halevy was admitted to the Academy in 1886.

Halévy, JOSEPH, an eminent French orientalist and traveller, was born 15th December 1827, at Adrianople. In 1868 he travelled in northern Abyssinia; next he traversed (1869–70) Yemen in quest of Sabæan inscriptions for the French Academy—one of the most fruitful journeys ever made by an archæologist. No European face had been seen in the Jowf since the soldiers of Ælius Gallus had visited it in the year 24 A.D., and Halévy travelled as far north as Bled Nedjran (18° N. lat.), and was able to collect as many as 860 inscriptions. His chief books are *Mission archéologique dans le Yemen* (1872), *Essai sur la Langue Agaou, le Dialect des Falachas* (1873), *Voyage au Nedjrân* (1873), *Études Berbères* (1873), *Mélanges d'Épigraphie et d'Archéologie Sémitiques* (1874), *Études Sabéennes* (1875), *Études sur la Syllabaire Cunéiforme* (1876), *Recherches critiques sur l'Origine de la Civilisation Babylonienne* (1877), *Essai sur les Inscriptions du Safa* (1882), and *Mélanges de Critique et d'Histoire* (1883).

Halfa. See ESPARTO.

Half-blood, related through one parent only. When two persons have the same father, but not the same mother, they are called brothers or sisters consanguinean; when they have the same mother only, they are called brothers and sisters uterine. See SUCCESSION.

Half-pay is an allowance given in the British army and navy to commissioned officers who are not actively employed, and corresponds to the French *demi-solde*.

In the navy, officers are appointed to a ship to serve for the period during which she is in commission. At the end of that period, or if promoted or otherwise removed from her, they are placed on half-pay until again called upon to serve. As the number of naval officers always exceeds that of the appointments open to them, there are at all times many on the non-effective list receiving about 60 per cent. of the pay of their rank.

In the army, *permanent* half-pay, first granted in 1698, was abolished in 1884, *retired* pay being substituted for it. Under the provisions of the royal warrant of 1887, lieutenant-colonels who have held command for four years are placed on *temporary* half-pay (11s. a day) until promoted. Majors of seven years' regimental, or five years' staff service in that rank may claim promotion to half-pay lieutenant-colonelcies, and these or any officers of lower rank may be placed on the half-pay of their rank while incapacitated through ill-health, or as a punishment for inefficiency. Half-pay officers are eligible for any employment suited to their rank, but are not borne on the strength of any regiment.

Seconded officers are those who are extra-regimentally employed, but whose names remain on the rolls of their regiments, additional officers being appointed in their places. On the termination of such employment they are absorbed into the regiment as soon as vacancies occur in their proper rank.

Officers on *retired* pay are liable to be called upon to serve in case of national peril or great emergency.

Haliburton, THOMAS CHANDLER, colonial judge and author, was born at Windsor, Nova Scotia, in 1796, was called to the bar in 1820, and became a member of the House of Assembly. He was raised to the bench as chief-justice of the common pleas in 1829, and in 1842 became judge of the supreme court. In 1856 he retired from the bench, and took up his residence in England. In 1858 he received the degree of D.C.L. from the university of Oxford, and in 1859 entered parliament as Conservative member for Launceston. He is best known as the author of *Sam Slick*, the name of a Yankee clockmaker and pedlar, a sort of American Sam Weller, whose quaint drollery, unsophisticated wit, knowledge of human nature, and aptitude in the use of what he calls 'soft sawder' have given him a fair chance of immortality. The series of newspaper sketches in which this character had first been introduced was published in 1837 as *The Clockmaker, or Sayings and Doings of Samuel Slick of Slickville*; two later series followed in 1838 and 1840, and *The Attaché, or Sam Slick in England*, in 1843. Haliburton's other works include *A Historical and Statistical Account of Nova Scotia; Bubbles of Canada; The Old Judge, or Life in a Colony; Letter-bag of the Great Western; Yankee Stories*, and *Traits of American Humour; Nature and Human Nature; Rule and Misrule of the English in America*; and *Wise Saws and Modern Instances*. He died at Isleworth, 27th August 1865.

Halibut, or HOLIBUT (*Hippoglossus vulgaris*), the largest of all the flat-fish (Pleuronectidæ), in form more elongated than the flounder or the turbot, the eyes on the right side, the upper surface smooth, and covered with small soft oval scales,

Halibut (*Hippoglossus vulgaris*).

the colour brownish, marbled all over with darker markings, the under surface smooth and white. The halibut, though esteemed for the table, is not to be compared in quality with the turbot; its flesh, though white and firm, is dry and of little flavour. It is found from the coasts of Spitzbergen to Iceland, off Newfoundland, &c., and from Finland and Scandinavia to the British and French coasts, but is rare in the Channel. It is abundant off the Orkneys, especially in eddies where tides meet. It is also found on the coasts of New England, New York, California, and Kamchatka. It is a fish of great value to the Greenlanders, who preserve it for winter use by cutting it into long strips and drying it in the air. Oil is obtained from it in considerable quantity, chiefly from the bones. It attains a great size; specimens have

been caught in Europe weighing at least 500 lb., and one caught in Iceland was little short of 20 feet long.

Halicarnassus (originally called *Zephyria*), a Greek city of Caria in Asia Minor, situated on the Ceramic Gulf. It was founded by Dorian colonists from Trœzen, and defended by several citadels, one of which, Salmacis, was deemed impregnable. Early in its history it became one of the cities of the so-called Dorian Hexapolis, from which confederacy, however, it was eventually excluded. When the Persian power spread westward, Halicarnassus readily submitted to the dominion of the conquerors. During this period, however, about 500 B.C., a domestic tyrant, Lygdamis, rose to supreme power as a vassal of Persia; and his descendants, without forfeiting the Greek character, or ceasing to cultivate the Greek literature and arts, gradually extended their sway over all Caria. Amongst them was Mausolus, whose wife and sister Artemisia, to commemorate him after his death (353), erected the magnificent Mausoleum (q.v.) which was accounted one of the seven wonders of the world. It was under this king that the city attained its highest degree of splendour and prosperity. About twenty years later Alexander the Great destroyed the city by fire; but the inhabitants took refuge in the citadel, which successfully resisted his arms. The city was afterwards rebuilt, but it never recovered its ancient importance or prosperity. In the days of the Roman empire it had sunk into comparative insignificance. Halicarnassus was the birthplace of the Greek historians Herodotus and Dionysius. The site of the city is occupied by the modern Budrun. An account of the excavations conducted there will be found in Newton's *Discoveries at Halicarnassus* (1862–63).

Halicore. See DUGONG.

Halicz, a town of Austria, in the crownland of Galicia, is situated on the Dniester, 69 miles SSE. of Lemberg by rail. On a hill in the vicinity are the ruins of the once strongly fortified castle of Halicz, built in the 12th century, and the residence of the rulers of what was formerly the grand principality and kingdom of Halicz. From this word the name Galicia (q.v.) is derived. Pop. 3464.

Halidon Hill, an eminence in Northumberland, 2 miles NW. of Berwick, overlooking the Tweed, was the scene of a bloody conflict between the English and Scots, 19th July 1333, in which the latter were defeated, upwards of 10,000 of them (according to some authorities, 14,000) being left on the field.

Halifax, a thriving market-town, municipal, parliamentary, and county borough, in the West Riding of Yorkshire, is situated on the river Hebble, a feeder of the Calder, on the slope of an eminence, and is almost wholly surrounded by hills. It is 43 miles SW. of York, and 194 miles NNW. of London. Dr Whitaker derives its name from the four ways travelled by pilgrims converging towards the parish church, called Holy Ways; *fax* (as in *Carfax*) being Norman-French for 'forks' or ways. A more popular derivation is that it means 'Holy Face,' from a representation of the head or face of John the Baptist having been at a remote period kept in a chapel where now stands the parish church of St John the Baptist. Its situation is pleasing, and its general appearance handsome; while its ample supply of water-power and of coal, its facilities for transport both by water and by leading lines of railway, and its position in proximity to many of the great towns of the north of England contribute materially to its manufacturing and commercial importance. Some Flemish artisans had settled here in the reign of Henry VII. The ecclesiastical architecture of Halifax strikes every visitor. The parish church of St John, restored in 1879, is a fine specimen of Perpendicular Gothic; 'All Souls,' built at the expense of Edward Akroyd from designs by Sir G. G. Scott, is one of the best and most elaborate of all the churches of which he is the architect. The 'Square Church,' belonging to the Congregational body, was erected in 1855, and there are in all about forty Nonconformist churches. The town-hall, opened by the Prince of Wales in 1863, is a very ornate Renaissance edifice, from designs by Sir Charles Barry; the new post-office was opened in 1887. Another important building is the Piece Hall, erected in 1779 for the reception and sale of manufactured goods; it was presented to the corporation by Sir S. Ibbetson in 1868, and is now used as a Market Hall. Among the numerous public and private educational institutions of Halifax are the Heath grammar-school, founded in 1585, and the Blue-coat School. The school-board has the control of fully two-thirds of the school-children. The Crossley and Porter Orphan Home and School was built by the Crossley brothers at a great cost, and has an endowment of £135,894. In 1887 Mr J. Porter of Manchester (formerly of Halifax) augmented the endowment fund by a gift of £50,000. Halifax has four parks—Savile, Shrogg's, Akroyd, with free library, museum, and art-gallery, and the People's Park. The last, the gift of the late Sir F. Crossley (q.v.), is tastefully laid out from designs by Sir Joseph Paxton, and cost about £40,000. There are two theatres (one dating from 1888). The Public Libraries Act has been adopted; there are also a Mechanics' Institute and the Dean Clough Institute erected by the Crossleys for their work-people. There is a strong co-operative society (Halifax Industrial), with central stores erected in 1861 at a cost of £17,400, and twenty-eight branch stores.

The worsted and carpet trades are the staple industries. Crossley's carpet-works, the largest in the world, employ more than 5000 hands. The manufactured goods, other than carpets, are chiefly worsted coatings, fancy dress goods, damasks, and merinos. Cotton fabrics and woolcards are manufactured, while dyeing and hosiery trades are on an extensive scale. There is also some trade in corn; iron, chemicals, boots, and mill-machinery are manufactured, and freestone is quarried. The water-works, which are very complete, have cost the corporation about £675,000. Pop. (1851) 33,582; (1871) 65,510; (1881) 73,633; (1891) 82,864. The borough since 1832 has returned two members to parliament.

A strange old local law, relinquished in 1650, known as the Halifax Gibbet Law, was enacted here at an early period of the woollen manufacture, for the protection of the manufacturers against the thievish propensities of persons who stole the cloth when stretched all night on racks or wooden frames, called tenters, to dry. The Gibbet Law provided that all persons within a certain circuit, who had stolen property of or above the value of 13½d., were to be tried by the frith-burghers within the liberty; and, if found guilty, they were handed over to the magistrates for punishment, and were executed on the first market-day following by means of an instrument similar to the guillotine. See Watson's *History of Halifax* (1775; ed. by Leyland, 1869).

Halifax, the capital of Nova Scotia and the principal Atlantic seaport of Canada, is situated on the eastern or Atlantic coast of Nova Scotia, in 44° 39′ N. lat. and 63° 37′ W. long. It is the nearest to Great Britain of any city on the American continent, being but 2178 miles from Cape Clear. Previous to the founding of the city, the magnificent sheet of water that constitutes its

harbour was called by the Indians *Chebucto*, signifying the greatest of havens—a name not inappropriate for what is one of the finest harbours in the world. It is easily accessible at all seasons of the year, at all times of the tide, by ships of any tonnage; and is capable of affording safe anchorage to the whole British navy. The fact that it was selected as the American rendezvous of the ill-starred expedition of D'Anville against the British colonies in America in 1746 led to a demand on the part of those colonies that a place of such strategic importance should no longer be unoccupied by imperial troops. Their demand was ably supported by Lord Halifax, and accordingly an expedition was fitted out in 1749, under command of the Hon. Edward Cornwallis, which founded the city and gave to it the name of its English patron. It at once became the capital of the province, and the principal naval and military station of Great Britain in America, and has remained so ever since. It is garrisoned by imperial troops, and is strongly fortified—its supposed impregnability securing for it the appellation of 'the Cronstadt of America.' The dockyard, covering 14 acres, is one of the finest in the British colonies. Down to the close of the Napoleonic wars Halifax was little more than a military and naval *entrepôt;* but of late years it has assumed more and more the character of a commercial city. It is built on the western side of the harbour, and extends along it about two miles and a half. The streets are well laid out, and are lighted by electricity. The commercial portion of the city is built principally of freestone. Its water-supply is excellent, and statistics show it to be one of the healthiest cities in America. It is the residence of the Roman Catholic archbishop of Halifax (whose archiepiscopal see includes Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland) and of the Church of England bishop of Nova Scotia. It is also the seat of Dalhousie University and of a large number of other educational institutions, including a school for the blind, and one for the deaf and dumb. In common with the rest of the province, its public schools are free, and attendance at them between certain ages is compulsory. It is the eastern or Atlantic terminus of the Intercolonial Railway of Canada and of the Canadian Pacific Railway, and has lines of steamers connecting it with London, Liverpool, New York, Boston, Bermuda, the West Indies, St Pierre, and both the east and west coasts of Newfoundland. It has also the largest graving-dock (580 by 102 feet) in America, constructed in 1880–89, at a cost of $1,000,000, and capable of receiving the largest ship afloat. The proximity of Halifax to the coalfields of Pictou and Cape Breton and its extensive wharf accommodation make it a favourite coaling station for steamers navigating the North Atlantic. Its population in 1881 was 36,100; its population at the census of 1891 was 38,556. Dartmouth, on the opposite shore of the harbour—practically a suburb of Halifax—has a population of 6200. In an average year the foreign trade of the port amounts to $10,000,000 or $12,000,000. The total number of vessels entering and clearing the harbour is from 2000 to 3000, with a tonnage of 1,500,000 tons.

Halifax, CHARLES MONTAGU, EARL OF, poet and statesman, who owed his introduction to political power to his facile skill in verse-making, was the nephew of the famous Parliamentary general, the Earl of Manchester, and was born at Horton, in Northamptonshire, 16th April 1661. He was educated at Westminster School and Trinity College, Cambridge, where he formed a life-long friendship with Newton. His most notable poetical achievement was a parody on Dryden's *Hind and Panther*, entitled *The Town and Country Mouse* (1687), of which he was joint author with Matthew Prior; but his poetry would hardly have made his name remembered in the 19th century. In the following year, through the influence of the Earl of Dorset, he became member for Maldon in the Convention Parliament, and soon developed a decided talent for financial business. Retaining his seat in William III.'s first parliament, he was appointed in 1692 a Commissioner of the Treasury. On the 15th December of the following year he proposed, in the House of Commons, to raise a million sterling by way of loan. William required money for his wars; the moneyed classes were tired of bubble companies, and knew not where to invest safely; and the landowners were weary of heavy taxation: so the National Debt was established. In the spring of 1694 money was again wanted, and Montague supplied it by originating a national bank, a scheme for which had been laid before government by William Paterson, three years before. The capital was to be £1,200,000, and the shareholders were to be called the Governor and Company of the Bank of England. As a reward for this service Montague was appointed Chancellor of the Exchequer in 1694. His next work was the recoinage in 1695, which he carried out successfully, appointing Newton warden of the Mint, and raising a tax on windows to pay the expense, instead of the obnoxious impost called hearth-money. At this crisis too he first introduced exchequer bills. On Godolphin's resignation in 1697 he became premier, but his arrogance and vanity soon made him unpopular, and on the accession to power of the Tories in 1699 he was obliged to accept the auditorship of the exchequer, and withdraw from the Commons as Baron Halifax. He was impeached before the House of Lords for breach of trust in 1701, and again in 1703, but the proceedings fell to the ground. During the whole of Anne's reign Halifax remained out of office, but was active in promoting the union with Scotland, and the Hanoverian succession. On the queen's death he was appointed a member of the council of regency, and on George I.'s arrival became an earl and prime-minister. His rule lasted only nine months, being terminated by death on 19th May 1715.

Halifax, GEORGE SAVILE, MARQUIS OF, statesman, was born in the year 1633. For the share he took in bringing about the Restoration he was created a viscount in 1668. In 1675 he opposed Danby's Test Bill, and in 1679 by a display of extraordinary oratory procured the rejection of the Exclusion Bill. Three years later he was created a marquis, and made Lord Privy Seal. On the accession of James II. he became president of the council, but was dismissed in 1685 for his opposition to the repeal of the Test Act and the Habeas Corpus Act. He was one of the three commissioners appointed by James II. to treat with William of Orange after he landed in England. After the flight of James, Halifax tendered his allegiance to William III., and under him resumed the office of Lord Privy Seal; but, subsequently joining the opposition, he resigned his post in 1689. He died 20th April 1695. Shaftesbury was the sole rival as an orator of this

> [illegible] of piercing wit and pregnant thought,
> Endued by nature and by learning taught
> To move assemblies.—DRYDEN's [illegible]

As a minister he was a failure, owing to his frequent changes of side; yet he was not a fickle party-man, but rather a philosophic statesman, who, in order to serve his country, was compelled by the excesses of party to adopt this course—such at least is the defence he lays down in his *On the Character of a Trimmer*. The poet-musician Henry Carey (q.v.) is believed to have been his natural son. See his *Life and Letters*, by H. C. Foxcroft (1898).

Haliotis, a genus of gasteropodous molluscs, of the family Haliotidæ, order Prosobranchiata; shell widely open, ear-shaped, pierced on the outer margin by a series of holes which are closed in the course of growth after ceasing to be of use in containing the pallial folds. The shell, on account of its beautifully iridescent Nacre (q.v.), is much used for the purposes of ornament. In some parts of Italy it is called Venus's ear; it is the 'mother-of-pearl' of old English writers, and the 'ormer' (contracted from *oreille de mer*) of the French. The animal itself, in a living state, exhibits great beauty of colours. It inhabits the littoral zone, adhering to rocks like the limpet; one Japanese species, however, is found in deep water. Several species are used for food in different parts of the world. The genus has a wide distribution, being found in every part of the ocean from the Channel Islands southwards. Seventy-five recent and four fossil species, commencing in the Miocene period, are known.

Halitherium. See DUGONG.

Hall, the large principal apartment of the castles and mansions of the middle ages. The hall is of very ancient origin. The earliest Saxon buildings we have any record of are the palaces of the kings, and these seem to have consisted of one large hall, in which the king, his courtiers or 'hearth-men,' and all his retainers dwelt together, eating at the same table, and sitting round the same fire; and one other chamber, in which the king and his hearth-men slept, while his retainers slept in the hall. In the Norman keep the hall occupied the whole of the first floor—the private apartment of the lord of the castle being on the floor above. In the 12th century halls of a more commodious kind came to be erected in the courtyards of the castles, with the private apartments at one end and the kitchen offices at the other. The same arrangement prevailed, with slight modifications, during the 12th and 13th centuries. In the 14th and 15th centuries, when England was more settled and prosperous, and manners more refined, numerous apartments became necessary. The hall, however, still retained its place as the chief apartment. In it the king or the lord of the manor gave audience, administered justice, received and entertained his retainers and guests, and performed all the public acts of feudal life.

At one end of the hall was a raised platform or dais, on which the table of the lord of the manor was placed, and where his more honoured guests sat along with him. This end of the hall was usually lighted with large oriel windows, and communicated with a building which contained the lord's solar, or bedroom and parlour, on the upper floor, and the wine-cellar below. The retainers sat at a table which ran along the lower part of the hall. This part was not always in the cleanest and sweetest condition, and hence it received the name of 'the marsh.' The entrance porch was at the lower end of the hall, where also a passage was cut off by a screen. This passage gave access to the kitchen, pantry, and buttery, and above the passage a gallery for musicians was frequently constructed. Survivals of such medieval dining-halls may be found in the Oxford and Cambridge colleges, with their high tables, portraits, stained glass, &c., as also in the halls of the Inns of Court and of some of the London guilds.

The hall partook of the style of architecture prevailing at the time when it was built, and being a large and important apartment was generally ornamental in its character. The roofs especially were very carefully and elegantly constructed, as many still remaining show. The hall was essentially a part of feudal architecture. When that system gave way, the large common halls were abandoned and private dining-rooms substituted. Many old ones, however, still remain; but their use is changed. The hall of the king's palace, now called 'Westminster Hall,' built by William Rufus, and restored by Richard II., is the finest example in England, being 300 feet long and 100 feet broad. See also MUNICIPAL ARCHITECTURE.

Hall, or SCHWÄBISCH-HALL, a town of Würtemberg, is beautifully situated in the deep valley of the Kocher, 33 miles by rail E. by S. of Heilbronn. Like other places in whose names the word Hall or Salz occurs, Hall has considerable saltworks, the brine being obtained from Wilhelmsglück, 5 miles distant, and producing annually nearly 80,000 cwt. of salt. There are also cotton-spinning and weaving, silk and machine manufactures, and tanneries. The Gothic church of St Michael (1427–1525) has excellent wood-carvings. In 1276 Hall was made a free imperial town; it had enjoyed since 1228 the right of minting money; here were coined the first silver *heller* (*häller*) or farthings. In 1802 it was added to Würtemberg. Pop. 9125.

Hall, a town of Austria, in Tyrol, is situated on the Inn, 6 miles by rail E. of Innsbruck. The parish church contains a monument to Speckbacher, the Tyrolese patriot of 1809. About 7 miles north of the town is the Salzberg, from the mines in which salt brine is conveyed to the pans of Hall in wooden pipes. Here 150,000 cwt. of salt are produced annually. Hall received town rights in 1303. It is a health-resort. Pop. 5756.

Hall, BASIL, writer of travels and miscellaneous works, was born in Edinburgh, 31st December 1788. He was the son of Sir James Hall of Dunglass, baronet (1761–1832), the founder of experimental geology (see GEOLOGY), also distinguished as a chemist and as author of a work on Gothic architecture. Basil entered the navy in 1802, and became post-captain in 1817. When Lord Amherst was sent on a mission to the court of Peking in 1816, Hall commanded a sloop in the naval escort, and visited some places along the western coast of the Corea which were little known to Europeans. The chief results of his explorations were published in *A Voyage of Discovery to Corea and the Great Loo-Choo Islands* (1818), a book which took the popular fancy. After this he wrote *Extracts from a Journal written on the Coast of Chili, Peru, and Mexico in 1820–22; Travels in North America in 1827–28* (a work that was violently assailed by the American press); and, also popular, *Fragments of Voyages and Travels* (9 vols. 1831–40). *Hainfeld* (1836), a semi-romance, and *Patchwork* (1841), a collection of tales and sketches, also came from his pen. He was a Fellow of the Royal Societies of London and Edinburgh, and a member of the Astronomical Society of London, and the author of various articles in the scientific journals of the day. He died insane in Haslar Hospital, Gosport, 11th September 1844.

Hall, CHARLES FRANCIS, Arctic explorer, born in Rochester, New Hampshire, in 1821, was successively a blacksmith, journalist, stationer, and engraver, and, becoming interested in the fate of the Franklin expedition, devoted his leisure to gathering information about Arctic America. He made two search expeditions, in 1860–62 and 1864–69, living alone among the Eskimo, and bringing back some relics and the bones of one of Franklin's company; and in 1871 he sailed in command of the government ship *Polaris*, on an 'expedition to the North Pole.' He took his vessel for 250 miles up the channel leading from Smith's Sound, and on 29th August reached 82° 16′ N.—at that date the highest northern latitude ever reached;

then turning southward, he went into winter-quarters at Thank God Harbour, Greenland (81° 38′ N.). Here, on his return from a sledge expedition to the north, he was taken suddenly ill, and died 8th November 1871; over his grave a grateful epitaph was placed by the British polar expedition in 1876. His companions left Thank God Harbour in August 1872. In October, through the ice-anchor slipping, nineteen men were left with stores on a floe, and only after severe sufferings were they rescued by a sealer off the Labrador coast in the following April. The leaking *Polaris* was beached on Littleton's Island, and in June 1873 the party set out for Upernivik in two boats which they had constructed; they were ultimately picked up by a Dundee whaler near Cape York. The charts published by the expedition are often incorrect and misleading, but among the valuable results of Hall's work were the exploration of the West Greenland channel, and the extension of Greenland and Grinnell Land a degree and a half north. Hall published *Arctic Researches, and Life among the Esquimaux* (1864); and from his papers largely was compiled the *Narrative of the Second Arctic Expedition* (Washington, 1879).

Hall, Chester Moor (1703–71), a gentleman of Essex who in 1733 anticipated Dollond in the invention of the achromatic Telescope (q.v.).

Hall, Christopher Newman, Congregational minister, was the son of John Vine Hall, author of *The Sinner's Friend*, and was born at Maidstone on 22d May 1816. Having graduated at London University, he preached in Hull 1842–54, and then removing to London, was till 1892 minister of Surrey Chapel or Christchurch, Lambeth, which was originally founded by Rowland Hill. He enjoyed wide repute as an eloquent and popular preacher, and is the author of several works of a devotional character, some of which, as *Come to Jesus*, *The Call of the Master*, and *The Man Christ Jesus*, have had an enormous sale. He has also written *Antidote to Fear*, *Meditations on the Lord's Prayer*, *Pilgrim Songs*, *In Cloud and Sunshine*, &c. See his *Autobiography* (1898).

Hall, or **Halle,** Edward, English historian, was born in London in 1499, of a family settled in Shropshire, but of German descent. He was educated at Eton, became scholar of King's College, Cambridge, in 1514, and junior Fellow in due course, next studied at Gray's Inn, and heard some of the lectures of Wolsey's foundation at Oxford. He became one of the common serjeants and undersheriff of the city of London, and afterwards a judge in the sheriff-court, and died in 1547, in the same year with Henry VIII. Next year his history was printed from his manuscript by Richard Grafton, under the title, *The Union of the Two Noble Families of Lancaster and Yorke*. It was composed mostly in his younger years, but was only brought down to 1532; the rest, down to 1546, was completed by Grafton. The exceptionally large number of variations in the copies make this thick black-letter folio something of a bibliographical curiosity.

Hall's work is one of the finest of our early histories, and the stately dignity of its style and reality of its figures had a charm for the dramatic sense of Shakespeare. To the student of the reign of Henry VIII. it is especially valuable as the truthful and intelligent evidence of an eye-witness, and if his account of his king is too uniformly eulogistic, we must remember how inestimably valuable to his legal mind was the present blessing of a settled domestic peace after the bloodshed and distraction of the Roses. Hall loves to describe with detail scenes of pomp and pageantry, such as made splendid the early years of Henry's reign—a taste that harmonises well with the stately and pompous Latinisms of his English. The best edition is that by Sir Henry Ellis (1809).

Hall, James, LL.D., geologist, was born at Hingham, Massachusetts, 12th September 1811, and in 1837 was appointed one of the New York state geologists. His final report on the western part of the state appeared in 1843. Of his other works the chief is his important *Palæontology of New York* (vols. i.–v. 1847–79); he also contributed to the geological surveys of Iowa, Wisconsin, and Canada, and published nearly 250 separate papers. A member of numerous scientific bodies, he died 7th August 1896.

Hall, Joseph, bishop and divine, was born 1st July 1574, at Ashby-de-la-Zouch, Leicestershire. He was educated at Emmanuel College, Cambridge, of which he became a Fellow in 1595. Taking orders, he held successively the livings of Halstead and Waltham, in Essex, and the deanery of Worcester. In 1617 he accompanied James to Scotland to help establish Episcopacy, and in this and the next year was one of the English deputies to the synod of Dort. He was consecrated Bishop of Exeter in 1627, and in 1641 was translated to Norwich. The later years of his life were saddened by persecution. He was accused of Puritanism, though he zealously defended Episcopacy, and he incurred the enmity of Archbishop Laud. In 1641, having joined the prelates who protested against the validity of all laws passed during their enforced absence from parliament, he was committed to the Tower, and threatened with a prosecution for high-treason, but was set at liberty at the end of seven months, on finding bail for £5000. Shortly after his return to Norwich his revenues were sequestrated and his property pillaged. Thereafter he rented a small farm at Higham, near Norwich, to which he retired in 1647. There he died 8th September 1656. His works, including *Contemplations*, *Christian Meditations*, *Episcopacy*, and *Mundus Alter et Idem*, a Latin satirical romance of an unknown country in Terra Australis, were edited by the Rev. Josiah Pratt (10 vols. 1808), and by Peter Hall, a descendant (12 vols. 1837–39). His poetical *Satires: Virgidemiarum* (1597–98) Pope calls 'the best poetry and the truest satire in the English language.' Hallam, however, accuses him of being harsh and rugged, obscure, and ungrammatical. See Life by George Lewis (1886).

Hall, Marshall, physician and physiologist, the son of Robert Hall, who introduced the practice of bleaching cotton with chlorine, was born at Basford, in Nottinghamshire, 18th February 1790. After studying medicine at Edinburgh (1809–14), Paris, Göttingen, and Berlin, he settled at Nottingham in 1817; and practised in London from 1826 until 1853. He died at Brighton, 11th August 1857. Though not the original observer of the phenomena of the reflex action of the spinal system, Hall claims to have been the first to show their independence of sensation, to work out the laws of their causation, and to apply the knowledge of them to the comprehension of nervous diseases. His investigations on this subject were published in two papers (1833–37). His name is also associated with a well-known method of restoring suspended respiration (see Respiration, Artificial). Besides the above-mentioned papers, he wrote several works on diagnosis (1817), the circulation (1831), *The Inverse Ratio between Respiration and Irritability in the Animal Kingdom* (1832), and on the nervous system and its diseases. A bibliography will be found in *Memoirs of Marshall Hall*, by his widow (1861).

Hall, Robert, dissenting preacher and writer, was born at Arnsby, near Leicester, May 2, 1764.

Feeble in body but precocious in intellect, he learned to read before he could speak. He was educated at a Baptist academy at Bristol (1778–81), and at King's College, Aberdeen (1781–85), where he formed an intimate companionship with (Sir James) Mackintosh. Immediately after his graduation he was appointed assistant minister and tutor in the academy at Bristol. Here his eloquent preaching attracted overflowing audiences. As an orator he was fluent, rapid, and impressive, and was liberal, but not heterodox, in his religious views. In consequence of a disagreement with his colleague, he went in 1790 to Cambridge, where by his powerful and vivid eloquence he rose to the highest rank of British pulpit orators. His writings, apart from sermons, are few; the more important are an *Apology for the Freedom of the Press* (1793) and *On Terms of Communion* (1815). In 1806 he settled in Leicester; but returned in 1826 to Bristol, where he died February 21, 1831. A complete edition of his works, with a memoir by Dr O. Gregory, and Observations on his Preaching by John Foster, was published at London (6 vols. 1831–33; 11th ed. 1853).

Hall, Samuel Carter, author and editor, fourth son of Colonel Robert Hall, was born at Geneva Barracks, County Waterford, 9th May 1800. Coming to London from Ireland in 1822, he studied law, and became a gallery reporter for the *New Times*. He established the *Amulet* (1825), an annual, which he edited for several years; succeeded the poet Campbell as editor of the *New Monthly Magazine;* was sub-editor of the *John Bull;* and did other journalistic work before he founded and edited the *Art Journal* (1839–80), which has done so much to create a public for art. He was a pertinacious and indefatigable worker and skilful compiler, the joint works written and edited by Mr and Mrs S. C. Hall exceeding 500 volumes. Amongst these were *Ireland, its Scenery,* &c. (illus. 1841–43); *The Book of Gems; British Ballads,* one of the fine-art books of the century; and *Baronial Halls.* A testimonial of £1600 was presented to him by friends in 1874, and in 1880 he received a civil-list pension of £150 a year. He died 16th March 1889. During his lifetime he had associated with most of the best men and women of his time, and showed a benevolent and helpful disposition. See his *Retrospect of a Long Life* (2 vols. 1883), and Mrs Mayo's 'Recollections of Two Old Friends' (*Leisure Hour*, May 1889).

Mrs S. C. Hall (Anna Maria Fielding), novelist, and wife of the preceding, was born in Dublin on 6th January 1800. She was brought up by her widowed mother at Graige, on the coast of Wexford, and in her fifteenth year came to London, where her education was completed. In 1824 she married Samuel Carter Hall, who encouraged her to write, and was her guide and counsellor in the composition of her tales and novels, which owed much to his pruning and polishing. She possessed, however, a genuine and spontaneous literary gift. Her first work, *Sketches of Irish Character* (1828), established her reputation. She wrote nine novels, and hundreds of shorter stories, including *The Buccaneer* (1832); *Tales of Woman's Trials* (1834); *The Outlaw* (1835); *The French Refugee*, a drama, which in 1836 was acted for about fifty nights at the St James's Theatre, London; *Uncle Horace* (1837); *Lights and Shadows of Irish Character* (1838); *Marian* (1839); *Midsummer Eve* (1843); *The Whiteboy* (1845), &c. Her *Stories of the Irish Peasantry* appeared originally in *Chambers's Journal*. Besides assisting her husband in various works, and by contributions to the *Art Journal*, she furnished numerous articles to periodicals, edited the *St James's Magazine* for a year, and wrote various books for the young. Of these *Uncle Sam's Money-box* is one of the best. She assisted in the formation of the Governesses' Benevolent Institution, a hospital for consumptives, and the Nightingale Fund, which resulted in the endowment of a training-school for nurses. Mrs Hall died January 30, 1881.

Hallam, Henry (1777–1859), historian, son of John Hallam, Canon of Windsor and Dean of Bristol, was born at the former town, 9th July 1777. He studied at Eton College with zeal and success (his Latin verses in the *Musæ Etonenses* were esteemed by competent judges among the best in the collection). He matriculated at Christ Church, Oxford, 20th April 1795, and proceeded B.A. 1799, M.A. 1832. The modern system of prizes was not yet in existence, and if he did nothing tangible at the university, it was because there was nothing to be done. Certainly all through he worked strenuously. He next read law in chambers in Lincoln's Inn, was admitted a member of the Middle Temple, and called to the bar by that society in 1802. His inn elected him a bencher in 1841, a somewhat rare honour for a non-practising barrister, as Hallam from the first gave himself entirely to literary pursuits. He had a small but sufficient fortune of his own, whilst his Whig friends in due time gave him various appointments—a commissionership of stamps among the rest. In 1805 he was engaged to write for the *Edinburgh Review* (Byron's famous satire alludes to him as 'classic Hallam, much renowned for Greek'), but it was not till he was over forty that he published his first great work. This was his *View of Europe during the Middle Ages.* It at once gave him a foremost place among English historians. He received in full measure such honours as fall to the lot of successful scholars. He was created a D.C.L., and elected a Fellow of the Royal, the Antiquarian, and many other learned societies at home and abroad. He was also a trustee of the British Museum, in which institution he took a great interest.

His life was almost without external incident. Its course was narrow and retired, yet within it he was both singularly fortunate and unfortunate. He had no money cares, he chose his own path in literature, and its very drudgery was delightful to him. He was fond of travel and of the society of cultivated men, and he enjoyed both. He was universally respected and admired. He had married a daughter of Sir Abraham Elton of Clevedon Court, Somersetshire, and the marriage was a happy one. He was devotedly attached to his wife and children; but there was some strain of physical weakness in the family. Of many children, only four survived early life. One of them died suddenly at Vienna. He was the Arthur Henry Hallam (1811–33) of *In Memoriam.* That work, rather than the fragments he left, full of promise as these were, will preserve his name. Hallam felt the loss keenly. He spoke of himself as one 'whose hopes on this side the tomb are broken down for ever;' but fate had not exhausted its malice. His wife died in 1840. The younger son, Henry Fitzmaurice Hallam (1824–50), was struck down abroad like his brother. A sister had predeceased him. The father lived on for yet nine years. In the shadowy joys of literature he found some consolation for those deep pangs which learned and unlearned feel with equal anguish. One daughter, wife to Colonel Cator of Pickhurst, in Kent, remained to soothe with pious care his last years. He lived with her till his death, 21st January 1859. He was buried with his wife and children in Clevedon Church, 'in a still and sequestered situation on a bare hill that overhangs the Bristol Channel.' A statue by M. Theed was erected to him in St Paul's Cathedral in 1862.

Hallam's position as an historian rests upon three great works. (1) *View of the State of Europe during*

the Middle Ages (2 vols. 1818), the object of which is 'to exhibit in a series of historical dissertations a comprehensive survey of the chief circumstances that can interest a philosophical inquirer during the period usually denominated the middle ages.' Special attention is accordingly given to the modes of government and constitutional laws. (2) *The Constitutional History of England from the Accession of Henry VII. to the Death of George II.* (2 vols. 1827). The starting-point is so fixed, because Hallam had already discussed the antecedent portion in the eighth chapter of his *View of the State of Europe*. He did not go further, 'being influenced by unwillingness to excite the prejudices of modern politics.' This did not save him from a savage attack by Southey in the *Quarterly Review*. Macaulay made the book the subject of a brilliant panegyric in his well-known Essay. The work has survived both praise and blame. It is still the standard authority for the period over which it extends; the preceding period was treated by Stubbs; the subsequent, by Sir T. E. May. (3) *Introduction to the Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries* (4 vols. 1837–39). This exhibits an even greater range of information than Hallam's other works; but its extent prevented it from being so thorough as they are. The sources are not so original, and it is not of such permanent value as the *Constitutional History*. Neither extracts nor biographical details are given, but full analyses of the works discussed.

Hallam's scholarship is accurate, his learning is both wide and deep. He is perfectly honest and perfectly disinterested. He is very anxious to find out the truth and impart it to the reader; and his style is clear and correct. He had some defects. He was a Whig of the old school (he was keenly opposed to the first Reform Bill), and disposed to look at everything from a somewhat narrow party point of view. There is a want of colour and animation about his style, and there is little human interest in his work; he dissects the past, but he does not make it live again for his readers. He is an author 'rather praised than read,' or at least his works are rather consulted by the student than popular with the general reader. Possibly this is the fate he would himself have wished for them.

There is oddly enough no complete Life of Hallam. The best accounts are the obituary and funeral notices in the *Times*, 24th and 31st January 1859, and in the *Proceedings of the Royal Society of London* (vol. x. p. 12, 1859–60). See also Harriet Martineau's *Biographical Sketches*. *The Remains of Arthur Henry Hallam*, with a memoir by his father, appeared in 1834, and a brief notice of Henry Fitzmaurice Hallam was printed soon after his death. Editions, translations, and abridgments of Hallam's works are numerous.

Hallamshire, an ancient manor of the West Riding of Yorkshire, with Sheffield for its capital. It now gives name to a parliamentary division.

Halle, a city of Prussian Saxony, known as Halle an der Saale, to distinguish it from other places of the same name in Germany, is situated on the right bank of the Saale and on several small islands of the river, 20 miles by rail NW. of Leipzig. As an important railway centre, Halle has of late years rapidly increased in size, industry, and prosperity. Its famous university was founded in 1694 by Frederick I. of Prussia; after having been suppressed by Napoleon in 1806, and again in 1813, it was re-established in 1815 and incorporated with the university of Wittenberg, which had been dissolved during the war. At first a chief seat of the pietistic school of theology, Halle subsequently became the headquarters of the rationalistic and critical schools. In 1888 the university was attended by 1501 students, and had 116 professors and lecturers. The Francke Institutions rank amongst the most important establishments of the place (see FRANCKE). The noteworthy buildings and institutions embrace St Mary's church (1529–54); the Gothic church of St Maurice, dating from the 12th century, with fine wood-carvings and sculptures; the red tower 276 feet high, in the market-place, with a Roland statue in front of it; the town-hall; the remains of the Moritzburg, built in 1484, the ancient residence of the archbishops of Magdeburg; a deaconesses' home; a large penitentiary; the medical institutes and clinical hospitals; the agricultural institute; the university library (220,000 vols.); a provincial museum; an art collection; and an archæological and other museums. The most important industrial product of Halle is salt, obtained from brine-springs within and near the town, which have been worked from before the 7th century, and still yield about 114,500 cwt. annually. The men employed at the salt-springs, and known as 'Halloren,' are a distinct race, supposed by some to be of Wendish and by others of Celtic descent, who have retained numerous ancient and characteristic peculiarities. The industries next in importance after the salt-manufacture are machine-making, sugar-refining, printing, brewing, the manufacture of mineral oil, and fruit cultivation. A very active trade is carried on in machines, raw sugar, mineral oil, grain, and flour. Halle is the birthplace of Handel the composer. Pop. (1871) 52,639; (1880) 71,484; (1885) 81,949; (1891) 101,401.

Halle, originally a border fortress against the Slavs, became in the 10th century an appanage of the Archbishop of Magdeburg, and by the 12th century was famous as a commercial city. In that and the 13th century Halle was a powerful member of the Hanseatic League, and successfully withstood a fierce siege by the Archbishop of Magdeburg in 1435, but finally fell into his hands in 1478. Terribly impoverished during the Thirty Years' War, it was incorporated with Brandenburg at the peace of Westphalia. See works by Von Hagen (1866–67), Voss (1874), and Schönermark (1886).

Halle, ADAM DE LA. See DRAMA.

Hallé, SIR CHARLES, an eminent pianist, was born at Hagen, in Westphalia, 11th April 1819. He studied first at Darmstadt, and from 1840 at Paris, where his reputation was established by his concerts of classical music. But the revolution of 1848 drove him to England, and he ultimately settled in Manchester. He and his highly-trained orchestra were ere long familiar to the music lovers of the kingdom from London to Aberdeen. He did much to raise the popular standard of musical taste by familiarising the British public with the great classical masters. An LL.D. of Edinburgh (1884), and knighted in 1888, he died 25th October 1895. See his *Life and Letters* (1896). LADY HALLÉ (*née* Wilhelmine Neruda), violinist, was born at Brünn in Moravia, 29th March 1839. An organist's daughter, she made her début at Vienna in 1846, and three years later played first in London at the Philharmonic. She married in 1864 the Swedish musician Normann, and, after his death in 1885, Sir Charles Hallé.

Halleck, FITZ-GREENE, an American poet, born at Guilford, Connecticut, July 8, 1790. By his mother he was descended from John Eliot, 'the apostle of the Indians.' He became a clerk in a bank in New York in 1811, and in 1832 the private secretary of John Jacob Astor; in 1849 he retired, on an annuity of $200 left him by Astor, to his native town, where he spent the remainder of his days, and died November 19, 1867. From his boyhood Halleck wrote verses, and in 1819 he contributed, with Joseph Rodman Drake, a series of humorous satirical papers in verse to

the New York *Evening Post*. In the same year he published his longest poem, *Fanny* (2d ed., enlarged, 1821), a satire on the literature, fashions, and politics of the time, in the measure of *Don Juan*. He visited Europe in 1822, and in 1827 published anonymously an edition of his poems (3d ed., enlarged, 1845). In 1865 he published *Young America*, a poem of three hundred lines. His complete *Poetical Writings* have been edited by his biographer (1869). Halleck is a fair poet. His style is spirited, flowing, graceful, and harmonious. His poems display much geniality and tender feeling. Their humour is quaint and pungent, and if not rich, is always refined. See his *Life and Letters*, edited by James Grant Wilson (1869).

Halleck, Henry Wager, an American general, was born at Westernville, New York, 16th January 1815, and graduated at West Point in 1839. During the Mexican war he was employed in the operations on the Pacific coast, and for his gallant services was breveted captain in 1847. He took a leading part in organising the state of California, became captain of engineers in 1853, left the service in 1854, and for some time practised law in San Francisco. On the outbreak of the civil war he was commissioned major-general in the regular army, and in November 1861 was appointed commander of the department of the Missouri, which in a few weeks he reduced to order. In March 1862 the Confederate first line had been carried from end to end, and Halleck's command was extended so as to embrace, under the name of the department of the Mississippi, the vast stretch of territory between the Rocky Mountains and the Alleghanies. His services in the field ended with the capture of Corinth, with its fifteen miles of intrenchments, in May 1862. In July he became general-in-chief of all the armies of the United States; and henceforth he directed from Washington the movements of the generals in the field, until, in March 1864, he was superseded by General Grant. Halleck was chief of staff until 1865, commanded the military division of the Pacific until 1869, and that of the South until his death, 9th January 1872. His *Elements of Military Art and Science* (1846; new ed. 1861) was much used during the civil war; and he also published books on mining laws, &c.

Hälleflinta (Swedish), a very hard compact rock, yellow, red, brown, green, gray, or black. It is composed of an intimate mixture of siliceous and felspathic matter, with occasionally scales of chlorite or mica. In hand-specimens it might be readily mistaken for a compact felsite, but in good sections in the field it generally occurs in thin beds and bands. It appears to be a metamorphic rock —in some cases an altered volcanic mud.

Hallein, a town of Austria, 10 miles S. of Salzburg, is noted for its salt-works and saline baths. Salt is made to the amount of 220,000 cwt. annually. Pop. 3927.

Hallelujah, or Alleluia (Heb., 'Praise ye Jehovah'), one of the forms of doxology used in the ancient church, derived from the Old Testament, and retained, even in the Greek and Latin liturgies, in the original Hebrew. The singing of the doxology in this form dates from the very earliest times; but considerable diversity has prevailed in different churches and at different periods as to the time of using it. In general it may be said that, being in its own nature a canticle of gladness and triumph, it was not used in the penitential seasons, nor in services set apart for occasions of sorrow or humiliation. In the time of St Augustine the hallelujah was universally used only from the feast of Easter to that of Pentecost; but a century afterwards it had become the rule in the West to intermit its use only during the season of Lent and Advent, and on the vigils of the principal festivals. In the Roman Catholic Church this usage is followed.

Haller, Albrecht von, anatomist, botanist, physiologist, and poet, was born at Bern, 16th October 1708. He was a sickly but remarkably precocious child. After a severe course of study, at Tübingen, Leyden (where he graduated in 1727), London, Paris, Oxford, and Basel, he settled down to practise as a physician at Bern in 1729. There, in the course of seven years, his botanical researches, especially on the flora of Switzerland, and his anatomical investigations, spread his fame through Europe, and led to his being called (1736) to fill the chair of Medicine, Anatomy, Botany, and Surgery at the newly-founded university of Göttingen. Here he organised a botanical garden, an anatomical museum and theatre, and an obstetrical school; helped to found the Göttingen Royal Academy of Sciences; wrote a great number of anatomical and physiological works; took an active part in the literary movement which culminated in the golden age of Goethe and Schiller; and interested himself in nearly all the questions of the day. In 1753 this many-sided man resigned his offices and dignities at Göttingen and returned to his beloved Bern, where the rest of his life was spent, his energies being principally occupied with the duties of 'amman' or magistrate. Nevertheless he found time to write three political romances, and to prepare four large works on the bibliography connected with botany, anatomy, surgery, and medicine. Critics of the standing of Vilmar name him first among the regenerators of German poetry, and give him the credit of beginning the new epoch. His poems were descriptive, didactic, and (the best of them) lyrical. Haller died at Bern, 12th December 1777. His name is particularly connected with muscular irritability, the circulation of the blood, and numerous excellent descriptions, of an anatomico-physiological character, of important parts of the human body. Of his voluminous writings the chief were *Icones Anatomicæ* (1743-50), *Opuscula Anatomica Minora* (1762-68), *Disputationes Anatomicæ Selectiores* (1746-52), *Elementa Physiologæ Corporis Humani* (1757-66), *De Respiratione* (1746-49), *De Functionibus Corporis Humani Præcipuarum Partium* (1777-78), *Opuscula Pathologica* (1755), *Enumeratio Stirpium Helveticarum* (1742), *Opuscula Botanica* (1749), and *Gedichte* (1732; new ed. 1882). See Lives by Blösch and Hirzel (1877) and Frey (1879).

Halley, Edmund, astronomer and mathematician, was born at Haggerston, near London, 29th October 1656, educated at St Paul's School, and afterwards at Queen's College, Oxford, which he entered in 1673. Before leaving school he became an experimenter in physics, and noticed the variation of the compass. In 1676 he published a paper (in *Philosophical Transactions*) on the orbits of the principal planets, also observations on a spot on the sun, from which he inferred the sun's rotation on its axis. In November of the same year he went to St Helena, where he applied himself to the formation of a catalogue of the stars in the southern hemisphere, which he published in 1679 (*Catalogus Stellarum Australium*). Soon after his election as a Fellow of the Royal Society, he was deputed by that body to go to Danzig (1679) to settle a controversy between Hooke and Helvetius respecting the proper glasses for astronomical observations. In 1680 he was again on the Continent; with Cassini at Paris he made observations on the great comet which goes by his name (see Comet), and the return of which

he predicted. After his return to England he published in 1683 (*Phil. Trans.*) his theory of the variation of the magnet. The next year he made the acquaintance of Newton—the occasion being his desire to find a test of a conjecture which he had made, that the centripetal force in the solar system was one varying inversely as the square of the distance. He found that Newton had anticipated him, both in conjecturing and in demonstrating this fact. For an account of Halley's connection with the publication of the *Principia*, see NEWTON. In 1686 Halley published an account of the trade-winds and monsoons on seas near and between the tropics. Two years later he undertook a long ocean voyage for the purpose of testing his theory of the magnetic variation of the compass, and embodied the results of his observations in a chart (1701). In the following year he surveyed the coasts of the English Channel, and made a chart of its tides. In 1703 he was appointed Savilian professor of Geometry at Oxford, and two years later published his researches on the orbits of the comets. On the death of Sir Hans Sloane he became (1713) secretary of the Royal Society, and held that position until 1721. During this period he made valuable experiments with the diving-bell (see DIVING). In 1720, after the death of Flamsteed, he became astronomer-royal, and his last years he spent in observing the moon through a revolution of her nodes. He died at Greenwich, 14th January 1742. His *Tabulæ Astronomicæ* did not appear till 1749. Among his principal astronomical discoveries may be mentioned that of the long inequality of Jupiter and Saturn, and that of the slow acceleration of the moon's mean motion. He has the honour of having been the first who predicted the return of a comet, and also of having recommended the observation of the transits of Venus with a view to determining the sun's parallax—a method of ascertaining the parallax first suggested by James Gregory.

Halliwell-Phillipps, JAMES ORCHARD, a great Shakespearian scholar and antiquary, was born at Chelsea in 1820, the son of Thomas Halliwell. He studied at Jesus College, Cambridge, and, yet an undergraduate, began that long career as an editor which he kept up almost till the close of life. His studies embraced the whole field of our earlier literature, plays, ballads, popular rhymes and folklore, chap-books, and English dialects, and its fruits remain in the publications of the old Shakespeare and Percy societies. As early as 1839 he was elected Fellow of the Royal and Antiquarian societies. Gradually he came to concentrate himself upon Shakespeare alone, and more particularly upon the facts of his life, the successive editions of his *Outlines of the Life of Shakespeare* (1848; 8th ed. 1889) recording the growing results of his discoveries. For many years he waged a brave warfare with fortune, but in 1872 he took over the management of the property his wife (died 1879) inherited from her father, Thomas Phillipps, and assumed his father-in-law's name. In his quaint house at Hollingbury Copse near Brighton he accumulated an unrivalled collection of Shakespearian books, MSS., and rarities of every kind, and dispensing hospitalities to scholarly visitors from all parts of England and America, as well as giving princely benefactions of books to Edinburgh University, Stratford, and Birmingham. Here he died, January 3, 1889. The privately printed *Calendar* (1887) of his collection embraced as many as 804 different items. By his will it was first offered, at the price of £7000, to the corporation of Birmingham; but it was not accepted. Apart from Shakespeare, his *Nursery Rhymes and Nursery Tales of England* (1845) and *Dictionary of Archaic and Provincial Words* (1847; 6th ed. 1868) will keep his name from being forgotten. His magnificent edition in folio of the *Works of Shakespeare* (16 vols. 1853–65) was published at a price prohibitive to most students.

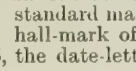
Hall-marks, or PLATE-MARKS, are authorised legal impressions made on articles of gold and silver at the various assay offices in the United Kingdom for the purpose of indicating to the public the true value and fineness of the metal of which they are composed. The marks are a series of symbols, which are stamped in an embossed style extending in a line of about one-half to three-quarters of an inch in length, the size of the marks varying with that of the articles on which they are impressed. They are usually stamped on every separate piece that is used to compose or make up an article. These symbols have the following representation: (1) The maker's mark, which is the initials of his Christian and surname, used since 1739. (2) The standard or Her Majesty's mark—viz. for gold of 22 carats, a crown and 22; for gold of 18 carats, a crown and 18; for gold of 15 carats, 15 and ·625; for gold of 12 carats, 12 and ·5; and for gold of 9 carats, 9 and ·375. These standard marks represent England; they are different for Scotland and Ireland. In the Edinburgh assay office the marks are: for gold of 22 carats, a thistle and 22; for gold of 18 carats, a thistle and 18; for gold of 15 carats, 15; for gold of 12 carats, 12; and for gold of 9 carats, 9. For Glasgow they are: for gold of 22 carats, a lion rampant and 22; for gold of 18 carats, a lion rampant and 18; for gold of 15 carats, a lion rampant and 15; for gold of 12 carats, a lion rampant and 12; and for gold of 9 carats, a lion rampant and 9. For Ireland the standard marks are: for gold of 22 carats, a harp crowned and 22; for gold of 20 carats—extra standard for Ireland only—a plume of feathers and 20; for gold of 18 carats, a unicorn's head and 18; for gold of 15 carats, 15 and ·625; for gold of 12 carats, 12 and ·5; and for gold of 9 carats, 9 and ·375. For England the silver standard marks are a lion passant for metal composed of 11 oz. 2 dwt. of fine silver to 18 dwt. of alloy, and Britannia for 11 oz. 10 dwt. fine silver to 10 dwt. alloy. For Scotland, a thistle for 11 oz. 2 dwt., and a thistle and Britannia for 11 oz. 10 dwt. at the Edinburgh assay office; and a lion rampant for 11 oz. 2 dwt., and a lion rampant and Britannia for 11 oz. 10 dwt. at the Glasgow assay office. For Ireland, a crowned harp for 11 oz. 2 dwt. No new standard of 11 oz. 10 dwt. is assayed and marked in Ireland. The figures in the gold standards denote the number of carats fine there are in any article bearing them, pure gold being reckoned at 24 carats; so that if a piece of gold-plate or jewelry is marked with a crown and 18 it indicates that it consists of 18 parts of pure gold and 6 parts of some other and inferior metal. This alloy would consist of three-fourths gold and one-fourth alloy. Gold as low in fineness as 9 carats is now legal, and as it is marked by the assay authorities there can be no deception if the public rightly understand the hall-marks introduced for their benefit. If they do not, then they are likely to be deceived. Nine-carat gold is a little over one-third pure gold. (3) The hall-mark of the assay towns: London, a leopard's head; Birmingham, an anchor; Chester, a dagger and three wheat sheaves; Sheffield, a crown; Newcastle, three castles; Exeter, a castle with three towers; Edinburgh, a castle; Glasgow, a tree, fish, and bell; Dublin, Hibernia. (4) The duty mark: the Queen's head, or head of the reigning sovereign, introduced in the year 1784. (5) The date mark: each assay office has now its letter or date mark, changed every year; 20 to 26 letters of the alphabet being used in rotation, and repeated in different styles of

letter. In London the assay year commences on the 30th May, and is indicated by one of twenty letters of the alphabet, A to U, omitting the letter J. The question has been raised whether the hall-marking system ought not to be discontinued.

The following table (made up from Cripps) shows specimens of the different alphabets used by the Goldsmiths' Company of London as date-letters from 1478; variety in the shape of the shields being also used as a further distinction:

1478 to 1498—Lombardic, caps., double cusps.	1696 to 1716—Court hand.
1498 to 1518—Black letter, small.	1716 to 1736—Roman, capitals.
1518 to 1538—Lombardic, capitals.	1736 to 1756—Roman, small.
1538 to 1558—Roman and other caps.	1756 to 1776—Black letter, capitals.
1558 to 1578—Black letter, small.	1776 to 1796—Roman, small.
1578 to 1598—Roman, capitals.	1796 to 1816—Roman, capitals.
1598 to 1618—Lombardic, capitals, external cusps.	1816 to 1836 Roman, small.
1618 to 1638—Italian, small.	1836 to 1856—Black letter, capitals.
1638 to 1658—Court hand.	1856 to 1876—Black letter, small.
1658 to 1678—Black letter, capitals.	1876 to 1896—Roman, capitals.
1678 to 1696—Black letter, small.	1896 to 1916—Roman, small.

The accompanying figure shows a Birmingham silver plate-mark. 1, the maker's initials; 2, the standard mark; 3, the hall-mark of Birmingham; 4, the duty-mark; 5, the date-letter for the year 1889.



See Cripps, *Old English Plate, its Makers and Marks* (1878; new ed. 1889); and Gee, *The Hall-marking of Jewellery practically considered* (1889).

Halloween, the name popularly given to the eve or vigil of All Hallows, or festival of All Saints, which being the 1st of November, Halloween is the evening of the 31st of October. In England and Scotland it was long consecrated to harmless fireside revelries, with many ceremonies for divining a future sweetheart. See Burns's 'Halloween' and Chambers's *Book of Days*. The similar Irish customs are illustrated in Maclise's 'Drop-apple Night.'

Hallstatt, an Austrian village near Gmunden, once a great Celtic capital. See IRON AGE.

Hallucinations. To realise in any proper way what memory is from the physiological point of view, we must assume that every impression on the senses is conducted by molecular movements through the nerves to the ultimate cells of the brain, which then undergo a certain molecular change that is revealed to consciousness as the qualities of the thing seen or heard or felt. By a process of instinctive reasoning the thing itself is thus instantly realised in the grown man, but not in the child. This molecular change in the cells may be evanescent, or it may be lasting. When lasting, the impression may be said to be 'registered,' so that it can come before consciousness again, and be 'remembered.' Each act of memory of the same impression in a healthy brain adds to the distinctness of the registration, and it is thus more and more easily recalled or suggested, either spontaneously or from without. The millions of brain-cells contain an inconceivable number of such registered impressions of things seen, heard, touched, smelt, and tasted, besides the impressions of past states of feeling, past trains of thought, and recombinations of them by means of the imagination. It is in no way thought a strange thing that we can recall all these in memory at any time, or that by unconscious processes of association they project themselves across the field of consciousness irrespective of our wills. It is not thought so very strange that, when we take a dose of opium or cocaine, the registered images lying in the brain-cells rise up and come across our consciousness so vividly that we cannot distinguish between them and real objects seen with the eyes. The same phenomenon often occurs in conditions of half sleep. In dreaming the impressions appear perfectly real to the half-consciousness existing at the time.

Now there are certain very sensitive people, who have an element of the morbid in their brain condition or heredity similar to the morbidness caused by a dose of cocaine. This being so, what is the difficulty in believing that those registered brain images should stand out, and seem to the consciousness as real as the original impression, and so produce a *hallucination*, or a subjective impression from an image already in the brain that is practically the same to the consciousness as the impression from a real object? This is in no way more remarkable than memory itself. It is simply more unusual. It is very questionable whether the original acts of memory of the young child are not all of the nature of hallucinations. The after recollections of things seen and of things imagined are certainly so real to some children that they confuse them with things seen or experienced. If a man can by using tests, and by the use of his reason, be made to know that the thing that appears to be seen and real is not so, and has no objective existence where he sees it, and that it is his brain that is playing him a trick, he has a sane hallucination. If he cannot be made to do so, and thinks it a real object, he is insane to this extent. The condition of hypnotism illustrates the origin of hallucinations better than almost anything else. Hypnotism (q.v.) is a modified, artificially-induced sleep, in which the consciousness is changed but not abolished, and the reasoning power much impaired. If a person hypnotised is told that a piece of ice is red-hot, he will not touch it, and if he is made to do so, he behaves as if he had touched hot iron. His whole mental condition is one of temporary hallucinations of every sort. Yet in the face of all these scientific facts and reasonable hypotheses and deductions we have persons calling in the aid of imaginary forces, 'telepathy,' 'spirits,' 'psychic force,' &c., to explain hallucinations, and associations formed for 'psychical research,' evidently on the theory that there can be a cause for hallucinations other than the registered images in the brain itself, together with altered conditions of consciousness. Many religious leaders and others in a state of intense brain excitement from religious or other causes have had hallucinations, after they had been sinning against nature's laws by depriving themselves of sleep and of exercise, and by exposing themselves to the contagion of morbid feeling interspersed by reason or common sense. Luther's seeing the devil, and throwing his ink-bottle at him, and Swedenborg's seeing spiritual beings among the ministers at the council board are certainly explicable on the theory of suggestion and a temporary morbidness of brain-working.

But, say the telepathists, 'two people have had the same hallucination at the same moment. How can that be explained on brain-cell principles?' If two people had been thinking of the same thing—for example, a dear friend or relative of both who was ill and supposed to be dying—and if both were sensitive persons, and their feelings were very excited at the time, what marvel is it if

through a rare coincidence they had seen the form of the dying friend? And if this impression happened to be near the time when he died, is it remarkable in the unscientific state of most minds that they made out it was the same moment that they both saw their friend's form appear and walk out at the door? When such duplicate hallucinations are probed by hard scientific methods it is always found that the hour of seeing them by the two people was not quite the same, that one had previously made a suggestion to the other forgotten in the excitement of the moment, or that the figures seen by them had on different clothing, or had quite different beards. Without far more evidence than has been brought forward by the pseudo-scientific believers in ghosts and apparitions, an age of science will never admit a hallucination to be anything but a brain phenomenon, obscure perhaps, but no more obscure than many other correlated facts of brain and mind. Every advance that is made in our knowledge of the brain and its working in relation to mind renders the rational and scientific explanation of all the hallucinations of the sane recorded by trustworthy, unbiassed observers more easy and probable, and makes less excusable the calling in to explain the facts of new and unknown 'forces' or 'influences' in nature beyond those we know and can scientifically investigate. Hallucinations may be of all the senses, and may be of every degree of variety and complication, from flashes of light to armies of men, from hummings in the ear to strains of 'celestial music.' But it has never been proved, as ought certainly to have occurred if there was any reality in those occult forces, that anything has ever been seen or heard by any one which the person might not possibly have seen or imagined previously, so that its image might be lying registered in his brain-cells; and no new knowledge has ever come to humanity from such sources. Hallucinations were much more common among primitive peoples and in the early ages of the world than they are now. See INSANITY.

Halluin, a town in the French department of Nord, 10 miles NNE. of Lille. Weaving of linen and woollen goods, bleaching, brick-making, and the manufacture of oil, chemicals, and chocolate are the principal industries. Pop. 9809.

Halmstad, a seaport of Sweden, and capital of the province of Halland, on the Cattegat, 75 miles SE. of Gothenburg, with trade in corn, wood, flour, and coal, and salmon-fisheries. Pop. 11,825.

Halogens, or SALT-PRODUCERS (Gr. *hals*, 'salt'), are a well-characterised group of non-metallic elements—chlorine, bromine, iodine, and fluorine—which form with metals compounds analogous to sea-salt. For haloid salts, see SALT.

Haloragæ, an order of thalamiflora dicotyledons, vegetatively reduced from Onagraceæ (q.v.). There are about seventy known species, herbaceous or half-shrubby; universally distributed, and almost all aquatic, or growing in wet places. The stems and leaves often have large air-cavities. The plants are insignificant in appearance, and the flowers generally much reduced. None of them have any important uses, except those of the genus Trapa (q.v.). The only British species are the Mare's Tail (*Hippuris vulgaris*) and the Water-milfoils (Myriophyllum).

Halos and **Coronæ.** Halos are circles of light surrounding the sun or moon, and are due to the presence of ice-crystals in the air. The commonest and usually the brightest has a radius of about 22 degrees—i.e. this is the angular distance from the sun to its inner edge. This size can be computed from the hexagonal shape and known refractive power of ice-crystals. The calculation shows that light passing through the sides of such a crystal is bent at an angle varying with the direction in which it falls on the crystal, but never less than 21½ degrees, which is therefore called the angle of minimum deviation, and in the greater number of cases not greatly exceeding that angle. If, therefore, the air between the observer and the sun or moon be filled with such crystals the light will be thrown outwards beyond the angle of minimum deviation, and will mostly appear at about 22 degrees distance from the sun or moon, forming a circle round it. As blue light is slightly more refrangible than red it is thrown farther out, and the halo appears coloured red inside and blue outside. Some of the crystals may, however, be lying so that the light enters at a side and leaves at one end, or *vice versâ*, in which case the angle of minimum deviation is about 46 degrees, at which distance a second fainter halo is frequently seen with colours in the same order as in the first. These colours are generally well seen in solar halos, but not in lunar, as the moon's light is too faint to give distinct colour to each part. In addition to the above, a third still larger halo has been seen. There are only four observations of this halo on record, and the radius has been estimated in the different cases at from 81 degrees to 90 degrees. The cause of this halo has not been ascertained. It is not coloured, and may be due either to some more complex form of ice-crystal or to internal reflection from the hexagonal crystals.

Another phenomenon sometimes seen with halos is the *Parhelic circle*, which is a white circle passing through the sun and parallel with the horizon. It is caused by light reflected from the surfaces of ice-crystals falling vertically through the air. When the sun is near the horizon this circle is intensified at distances of 22 degrees and 46 degrees from the sun, and forms parhelia or mock-suns, and another mock-sun is sometimes seen on this circle directly opposite the sun. A similar circle is also formed passing vertically through the sun by reflection from the upper and under surfaces of the ice-crystals. Halos are sometimes accompanied by contact arches, which are arcs of circles touching the halos of 22 degrees and 46 degrees; they are formed by long hexagonal prisms floating horizontally in the air, and are curved away from the sun when it is below 30 degrees altitude, but are concave towards it at greater elevations. Several other more complex forms of halo have been seen in the arctic regions, but are of rare occurrence in Britain.

Halos must not be confused with *Coronæ*, which are smaller coloured circles that appear round the sun or moon when they shine through thin cloud or mist. In these the red is the outermost colour, and several successive sets of coloured rings are usually formed. They are due to the diffraction the light undergoes in passing among the drops of which the cloud is composed. The radius of the first red ring of a corona varies from 1 degree to 3 degrees, according to the size of the drops, and the radii of the others are successive multiples of that of the first.

When the sun shines on a bank of fog a large bow of about 40 degrees radius, resembling a rainbow, but not so brightly coloured, is seen. It is often double, like the rainbow. Owing to the smaller size of the water-drops in a fog than in falling rain, the *Fogbow* is wider and fainter than the rainbow. The law determining the order of the colours—whether red inside or red outside—has not yet been thoroughly worked out. If the observer is standing on an elevated point so that his shadow falls on the fog, coloured rings called *Glories* or Anthelia are often seen. Five or six sets of colours have been observed, the outermost

having a radius not exceeding 12 degrees. In each ring the red is outside, showing that it is a diffraction effect like a corona, but the exact cause has not been determined. If the fog is very near, the observer's shadow is visible, forming what is known as the Brocken Spectre (see MIRAGE); and if the fog is thin the shadow looks farther away than it really is, and is therefore supposed by the spectator to be of gigantic size.

Halos, in religious art. See NIMBUS.

Hals, FRANS, the elder, portrait and *genre* painter, was born, probably at Antwerp, in 1580 or 1581, though some authorities give 1584 as the date. His parents, members of an old Haarlem family, returned to that city about 1600, and Hals studied under Karel van Mander and, according to some accounts, under Rubens. Some ten years later he married Anneke Hermanszoon, and in 1615 he was summoned before the magistrates and reprimanded for ill-treating his wife and for his drunken and disorderly life. A few weeks later his wife died, and in 1617 he married a woman of doubtful character, Lysbeth Reynier. In his later years, in spite of his unceasing industry, to which the numerous works from his hand in the continental galleries bear witness, he fell into poverty, and was relieved by the municipality of Haarlem, who in 1664 bestowed on him a pension of 200 florins. He died at Haarlem in 1666, and on the 1st of September was buried in the church of St Bavon. Hals is usually regarded as the founder of the Dutch school of *genre*-painting. His subjects of feasting and carousal are treated with marvellous vivacity and spirit, and as a portrayer of faces convulsed with laughter he is without a rival. His portraits are full of character, and catch with admirable subtlety the lightest shades of passing expression. Technically his work is masterly, his handling being most direct and powerful; but a certain hardness and crudeness of tone is frequently apparent in his rendering of flesh, and his later works have little variety of colouring, and show an unpleasant blackness in the shadows. Of his portrait groups eight noble examples are preserved in the museum of Haarlem, the finest being that dated 1633, representing the officers of the corps of St Adrian. The 'Mandoline Player' (1630), in the gallery of Amsterdam, is a typical example of his treatment of single figures. A series of excellent etchings after the works of Hals, by Professor William Unger, with text by C. Vosmaer, was published in Leyden in 1873. As a teacher he exercised a marked influence upon the development of Dutch art, Jan Verspronck, Van der Helst, Adrian van Ostade, Adrian Brouwer, and Wouwerman having been his pupils. An interesting view of the interior of his studio, dated 1652, by Job Berch-Heyde, another of his scholars, is in the Haarlem Museum.—His brother, DIRK HALS, a pupil of Abraham Bloemaert, was also an excellent *genre*-painter (*b.* before 1600, *d.* 1656); and several of Frans's sons were artists, the most celebrated being Frans Hals, the younger, who flourished from about 1637 to 1669.

Halstead, a market-town of Essex, on the Colne, 56 miles NE. of London. The parish church has a wooden spire and many old monuments; the free grammar-school dates from 1590. It has manufactures of crape, silk, and paper; straw-plaiting is also carried on. Pop. 6959.

Halyburton, THOMAS, a Scotch divine, was born at Dupplin near Perth in 1674, and was for eleven years minister of Ceres in Fife, and then for two professor of Divinity at St Andrews, where he died in September 1712. He was the author of several works, including *Natural Religion insufficient, and Revealed necessary, to Man's Happiness; The Great Concern of Salvation*; and *Ten Sermons preached before and after the Celebration of the Lord's Supper*. The works, especially the autobiographic memoir, of the 'Holy Halyburton' were once very popular among the people of Scotland; and even at the present day they are still read. They were published, together with an Essay on his Life and Writings, by Dr Robert Burns (London, 1835).

Halys. See ASIA MINOR.

Ham, properly the hind part or angle of the knee; but usually applied to the cured thigh of the hog or sheep, more especially the first. Ham-curing, or, what is the same thing, bacon-curing, is performed in a variety of methods, each country or district having its own peculiar treatment; these, however, relate to minor points. The essential operations are as follows: The meat is first well rubbed with salt, and either left on a bench that the brine may drain away, or covered up in a close vessel; after a few days it is rubbed again, this time with a mixture of salt and saltpetre, to which sugar is sometimes added, or with a mixture of salt and sugar alone. It is then consigned to the bench or tub for at least a week longer, after which it is generally ready for drying. *Wet salting* requires, on the whole, about three weeks; *dry salting*, a week longer. Mutton-hams should not be kept in pickle longer than about three weeks. Some hams are merely hung up to dry without being smoked; others, after being dried, are removed to the smoking-house, which consists of two and sometimes three stories; the fire is kindled in the lowest, and the meat is hung up in the second and third stories, to which the smoke ascends. The fire is kept up with supplies of oak or beech chips, though in some districts twigs of juniper, and in many parts of Great Britain peat, are used. Fir, larch, and such kinds of wood, on account of the unpleasant flavour they impart, are on no account to be used. The fire must be kept, night and day, in a smouldering state for three or four days, at the end of which time the ham, if not more than five or six inches deep, is perfectly smoked. As cold weather is preferable for the operation of curing, it is chiefly carried on during winter. Many of the country-people in those parts of England where wood and peat are used for fuel smoke hams by hanging them up inside large wide chimneys, a method common in Westmorland. The curing of beef and mutton hams is carried on chiefly in the north of England and Dumfriesshire in Scotland; that of pork-hams, on the other hand, is found in various countries, among the best known being those connected in commerce with the names of Belfast and Westphalia. Harris of Calne, Wiltshire, introduced an ammonia freezing-process available both summer and winter. Chicago (q.v.) is the chief centre of the enormous American industry of pork-packing. The imports of bacon and hams into the United Kingdom in 1888 amounted to 3,594,212 cwt., of a value of £8,343,387. Of this quantity the value from the United States was £3,874,170, from Denmark £1,389,047. The import of hams only in 1888 was 730,408 cwt., of the value of £1,929,602. The total value of the imports of bacon and hams in 1886 was £8,402,828; in 1894, £10,855,715. The total export of bacon and hams from the United States is valued at upwards of $30,000,000 a year. See PIG.

Ham, a town in the French department of Somme, on the river of that name, 12 miles SW. of St Quentin. Its ancient fortress or castle was rebuilt by the Comte de Saint Pol in 1470, and now is used as a state prison. It is memorable as the place of confinement of Joan of Arc, Moncey, and others; of Polignac, Peyronnet, and

Guernon de Ranville from 1831 to 1836; of Louis Napoleon from 1840 till 1846; and after the *coup d'état*, of the republican generals Cavaignac, Lamoricière, Changarnier, &c. Pop. 2837. See Gonnard, *Ham, son Château*, &c. (1864).

Ham, West, a suburb of East London, and a parliamentary and county borough of Essex, on the north bank of the Thames, opposite Greenwich. In fifty years its population grew from 10,000 to 204,903 (1891), principally owing to the Victoria and Albert docks and the gas works. It is a busy industrial parish, and has silk-printing, shipbuilding, distilling, and chemical manufactures. In 1885 it was made a parliamentary borough, returning two members to the House of Commons. Here is Mrs Elizabeth Fry's house, 'The Cedars.' East Ham, situated in the south-west of the same county, 1½ miles SW. of Barking, has a population of 9713. See Katharine Fry, *History of the Parishes of East and West Ham* (1888).

Ham, according to the writer of Genesis, was the second son of Noah, and the brother of Shem and Japheth. The name, however, as generally used, is geographical rather than ethnographical. The word Ham in Hebrew signifies 'to be hot,' and the descendants of this son of Noah are represented as peopling the southern regions of the earth, so far as known at that time—viz. Arabia, the Persian Gulf, Egypt, Ethiopia, Libya, &c. Ham has also been identified with Kemi ('black land'), an ancient name of Egypt; but for this identification there exists no satisfactory philological evidence. Philologists and ethnologists recognise as a distinct family of peoples and tongues a group which they call 'Hamitic,' classifying it as co-ordinate with the Aryan and the Semitic. See Africa, Vol. I. pp. 85, 86.

Hamadan, a town of Persia, in the province of Irak Ajemi, is situated at the northern base of Mount Elwend, 160 miles WSW. of Teheran. It contains some notable tombs—e.g. Avicenna's (q.v.) and others affirmed to be those of Mordecai and Esther. Being the centre of converging routes from Bagdad, Erivan, Teheran, and Ispahan, it is the seat of a large transit trade; and it carries on extensive manufactures of leather, and in a less degree of coarse carpets and woollen and cotton fabrics. Pop. 30,000. Hamadan is generally believed to occupy the site of the Median Ecbatana (q.v.).

Hamadryads. See Nymphs.—The name *Hamadryas* is given to a kind of Baboon (q.v.); and the *Hamadryas* or *Ophiophagus elaps* is the largest poisonous snake of the Old World, larger and more dangerous than any of the cobras, with which it has almost the same geographical range.

Hamah (Gr. *Epiphania*), the Hamath of the Bible, a very ancient city of Syria, on the Orontes, 110 miles N. by E. of Damascus. The town stands in the midst of gardens, though the streets are narrow and irregular, and the houses are built of sun-dried bricks and wood. The inhabitants, about 45,000, manufacture coarse woollen mantles and yarn, and carry on considerable trade with the Bedouins. Hamath seems to have come very early in conflict with the Assyrians, having been taken by them in 854 B.C. and again in 743, whilst two revolts of the people were crushed by the Assyrians in 740 and 720 B.C. After the Græco-Macedonian conquest of Syria, Hamah became known as Epiphania. In 639 it fell into Moslem hands, and, though it was held by Tancred from 1108 to 1115, it was again taken possession of by the Moslems. Abulfeda, the Arab geographer, was prince of Hamah in the 14th century. Four stones were discovered there in 1812 by Burckhardt, bearing inscriptions in an unknown language, now believed to be Hittite (q.v.).

Hamamelideæ. See Witch Hazel.

Hamann, Johann Georg, a German writer, born at Königsberg in Prussia, 27th August 1730. The incompleteness and aimlessness which characterised his education clung to him all his days: he made numerous starts in life, but followed no one calling for long; in turn, student of philosophy, of theology, of law, private tutor, merchant, tutor again, commercial traveller, student of literature and the ancient languages, and clerk, he at length settled down in Königsberg in 1767 as an official in the excise. Nevertheless he lived but meanly until the present by a patron, in 1784, of a sum of money raised him above want. He died at Münster, 21st June 1788. His writings are, like his life, desultory and without system; but even as such they exercised a perceptible influence upon Jacobi, Herder, Goethe, and Jean Paul. For in spite of their symbolical and oracular style, qualities which led to their author being designated the 'Magus of the North,' they contain the results of thoughtful and extensive reading, are rich in suggestive thought, encrusted with paradox and sarcasm, and thoroughly bristle with literary allusions. Hamann's independence and love of honest truth made him, however, unpopular with his contemporaries, except the more thoughtful few. Compare Roth's edition of his *Sämmtliche Schriften* (8 vols. 1821–45) or Gildemeister's (6 vols., including biography, 1857–73). See Lives by Poel (1874–76) and Claasen (1885).

Hambato, or Ambato, capital of Tunguragua province, Ecuador, in a sheltered amphitheatre on the northern slope of Chimborazo, 8860 feet above the sea. It was twice destroyed—by an eruption of Cotopaxi in 1698, and by an earthquake in 1796, but was speedily rebuilt. Pop. 12,000.

Hamburg, a constituent state of the German empire, includes the free city of Hamburg, the towns Bergedorf and Cuxhaven, and several suburbs and communes, with a total area of 158 sq. m. The free Hanseatic city of Hamburg is situated on the Elbe, about 75 miles from the German Ocean, 112 N. of Hanover, and 177 NW. of Berlin. Hamburg was founded by Charlemagne in 808, and for three centuries had to struggle hard to maintain itself against the marauding Danes and Slavs. It was made a bishopric in 831, and three years later an archbishopric. This last dignity was transferred to Bremen in 1223. The commercial history of Hamburg began in 1189–90, when the emperor granted it various privileges, amongst others a separate judicial system and exemption from customs dues. In 1241 it joined with Lübeck in laying the foundation of the Hanseatic League (q.v.), and from 1259 associated itself closely with Bremen also. From that time it increased rapidly in wealth and commercial importance, augmenting its territory by the purchase of the township of Ritzebüttel, at the mouth of the Elbe (where the harbour of Cuxhaven is now situated), and of several villages and islands in the vicinity of the town. Under the protection of the German emperors Hamburg soon became powerful enough to defend itself and its commerce both by sea and land, and carried on war for a considerable period against sea-rovers and the Danes. In 1510 it was made an imperial town by Maximilian I. It early embraced the doctrines of the Reformation. During the stormy period of the Thirty Years' War it never had an enemy within its walls. All through the years from 1410 to 1712 there were repeated risings of the populace against the governing classes. The disputes with Denmark finally ceased in 1768, that power renouncing all claim to Hamburg territory. The rapid commercial success and steadily increasing prosperity of the city were only momentarily checked by a severe

commercial crisis in 1763. On the other hand, the French Revolution drove many of the *émigrés* to Hamburg, and the ranks of its merchants were still further strengthened by refugees from Holland, when that country was overrun by the French in 1795. But eleven years later Hamburg itself was occupied by the French, and with that event there commenced for the city a period of great tribulation. In 1810 it was annexed to the French empire, but at the same time lost its commerce and its shipping trade. For having in 1813 admitted the Russians within its walls the city was cruelly treated by Davoût, Napoleon's general; and the cup of its misery was filled to the brim by the siege which Bennigsen began in that same year.

Between 1806 and 1814, when the French occupation came to an end by the capitulation of Davoût to the allies, the population decreased by nearly one-half, namely to 55,000, and had to endure losses of property estimated at £7,000,000. In the following year Hamburg joined the German Confederation as one of the four free cities, and its prosperity began rapidly to revive. Another calamity overtook the town in 1842: in three days one-third of Hamburg was destroyed by fire, and more than two millions sterling worth of property lost. That part of the town was, however, immediately rebuilt in modern style. The older portion is intersected by canals, which serve as waterways between the river and the warehouses. The ramparts have been converted into gardens and promenades. In 1843 an agitation was set on foot for a reform in the constitution, a step which it took eighteen years to carry into effect. On 1st October 1888 Hamburg entered the German Customs Union, though still retaining part of its territory as a 'free port.' This change has necessitated extensive alterations in the harbour: several quays have been built, warehouses constructed, steam-cranes erected, and the railway communication with the chief industrial centres of Germany improved. In 1890 new docks were in course of construction at Cuxhaven for the use of the great ocean-going steamers. The finest public buildings are the 'school house' (containing the town library of 400,000 volumes and 5500 MSS., and a natural history museum), town-house, picture-gallery, exchange, bank, post-office, and some churches. Of these last four are noticeable—St Nicholas, built from designs by Sir Gilbert Scott, as a memorial of the fire of 1842, a handsome Gothic building, with a spire 482 feet high; St Michael's, an 18th-century Renaissance church, with a spire 469 feet high; and St Catherine's and St James's, both Gothic edifices of the 14th and 15th centuries. In addition to numerous excellent schools and charitable institutions, Hamburg possesses a school of navigation, with which is connected an observatory, a zoological and a botanical garden, and several museums and art-galleries. Hamburg has played an important part in the history of the German stage.

Hamburg is the busiest commercial city on the continent of Europe, and the principal commercial seaport of Germany. Next to London it has the largest money-exchange transactions in Europe; the bank of Hamburg was founded so long ago as 1619. As a commercial centre its only rivals are London, Liverpool, Antwerp, and New York. Its manufactures, though a long way inferior in value to its commerce, are not unimportant. The principal are cigar-making, distilling of spirits, sugar-refining, brewing, engineering, iron-founding, manufacture of chemicals, india-rubber wares, furniture, starch, and jute, and shipbuilding. In 1865 the number of vessels that entered the port was 5186, with a gross burden of 1,223,000 tons; these figures rose to 5260 vessels and 2,118,000 tons in 1875, and to 6790 vessels and 3,704,000 tons in 1885, whilst in 1887 they were 7308 vessels and 3,990,000 tons. The number and tonnage of the vessels that cleared were about the same in the corresponding years. Of the vessels entering in 1887 about 36 per cent. were British. The imports have increased at an extraordinarily rapid rate: in 1864 they were valued at £57,976,000, in 1875 at £85,050,000, in 1885 at £102,300,000, and in 1887 at £111,948,800. These returns do not include bullion. The total value of the trade of Hamburg with Great Britain and her possessions amounted to £28,000,000 in 1887. Of the imports about one-half represent the value of goods brought into Hamburg by rail and river (Elbe) from the interior of the country. Next after Great Britain the countries with which Hamburg has commercial transactions of the greatest magnitude are the United States, the countries on the west and east coasts of South America, France, Holland and Belgium, Central America, Russia, the East Indies and China, and the east and west coasts of Africa. Hamburg owes a large part of its trade to its position as a distributing centre for commodities brought from distant parts of the world, to be afterwards sent to the different countries of Europe. In 1891 the total imports (without bullion) were valued at £138,270,000, and the exports at £121,795,000. Hamburg is a great port for emigration. The city was severely visited by cholera in autumn of 1892; there were 17,000 cases and 9000 deaths. In 1880 the population of the state was 518,468. In 1890 the population was, in the city, 323,923; suburbs, 245,337; rest of the territory, 53,270; total of the state, 622,530. There were 23,351 Catholics, and 17,877 Jews.

See Mönckeberg, *Geschichte der Freien und Hanse-Stadts Hamburg* (1885); Gaedechens, *Historische Topographie der Freien und Hanse-Stadt Hamburg* (1880); and two historical works by Gallois (1856–57 and 1861–65).

Hameln, a town and formerly a fortress of Hanover, occupies a commanding position on the Weser, 25 miles SW. of Hanover. It presents a quite medieval appearance, having many houses and buildings surviving from the Gothic and Renaissance periods of architecture. The chain-bridge which here crosses the Weser was completed in 1839, and is about 840 feet in length. The chief employments of the people are machine-making, iron-founding, wool-spinning, fish-breeding, brewing, and the manufacture of leather, paper, artificial manure, and chemicals. In the earliest times Hameln belonged to the Abbey of Fulda, and was a member of the Hanseatic Confederation. It suffered severely during the Thirty Years' War. Pop. (1885) 11,831. With this town is connected the well-known legend of the Piper (or Ratcatcher) of Hameln, who in 1284 freed the town from rats through the mystic charm of his pipe; but, when the people refused to pay him the promised reward, he exercised the power of his music upon the children of the place, and drew them away into the heart of an adjoining hill, which opened to receive them, and through which he led them to Transylvania. The story is familiar from Browning's 'Pied Piper of Hamelin.'

Hamerling, Robert, Austrian poet, was born of poor parents at Kirchberg in the Forest, in Lower Austria, on 24th March 1830. Having completed his studies at Vienna, Hamerling became a teacher in the gymnasium at Trieste in 1855. But at the end of eleven years of work, ill-health compelled him to retire. From that time down to the date of his death, on 13th July 1889, he lived at Gratz, almost entirely confined to his bed, but nevertheless leading a busy life as a writer of poetry. He began his career by the publication in 1860 of a volume of lyrics, *Sinnen und Minnen* (7th ed.

1886; each edition enlarged and improved). His lyric talent found expression also in such later works as *Das Schwanenlied der Romantik* (1862), *Amor und Psyche* (1882), and *Blätter im Winde* (1887). But his best books are three satirical epics—*Ahasver in Rom* (1866; 17th ed. 1889), *Der Kampf ums Dasein* (1869), and *Homunculus* (1888). In these books his theme is the problems that are knit about the inner nature of man, his mundane existence, and the institutions his mind has conceived and his hand has made. The structural conceptions are often grand, and the imagination bold; the emotional and descriptive colouring is both rich and truthful, the action vigorous, the philosophy ultra-modern; and there is a firm grasp of details, and a patient and clever use of them, mostly for satiric purposes. Satire is indeed one of the strongest elements in these epics. Hamerling's remaining works include *Venus im Exil* (1858); *Germanenzug* (1864), a translation of Leopardi's poems (1865); a novel, *Aspasia* (1875); a tragedy, *Danton und Robespierre* (1871); two or three other dramatic pieces; *Die sieben Todsünden* (1873); an autobiographical work, *Stationen meiner Lebenspilgerschaft* (1886); *Lehrjahre der Liebe* (Letters, &c. 1889). *Sämmtliche Werke* (Hamburg, 1889). See Life by A. Polzer (1889).

Hamerton, Philip Gilbert, was born, the son of a solicitor, at Laneside near Oldham, on 10th September 1834. According to the autobiography contained in the Life published by his widow in 1896, his youth was quite exceptionally unhappy. He commenced writing on art for magazines and reviews, and soon produced a volume of poems on *The Isles of Loch Awe* (1855), and *A Painter's Camp in the Highlands, and Thoughts about Art* (1862). In 1868 he published *Etching and Etchers* and *Contemporary French Painters;* a continuation of the latter appeared in the following year, *Painting in France after the Decline of Classicism.* From 1869 he edited the *Portfolio*. *The Intellectual Life* (1873) is in the form of letters of advice, illustrated by many examples, addressed to literary aspirants and others, of every class and in all circumstances; *Human Intercourse* (1884) is a volume of essays on social subjects, many of them dealing with intercourse as affected by nationality; *The Graphic Arts* (1882), finely illustrated, is 'a treatise on the varieties of drawing, painting, and engraving, in comparison with each other and with nature,' the analyses of the technique of the masters of the various arts being remarkable for discrimination and acumen; *Landscape* (1885), a superbly-illustrated volume, is not so much a treatise on landscape-painting as a work illustrating the influence of natural landscape on man. Other works are *Portfolio Papers* (1889), *French and English* (1889), *Man in Art* (1893), a couple of novels, and his *Life of Turner* (1879); and to this Encyclopædia he contributed the articles Painting, Rembrandt, and Turner. He lived many years in France, and died at Boulogne-sur-Seine, 6th November 1894.

Hamesucken, in Scots law, the offence of assaulting a man in his own house.

Hamilcar, next to Hannibal the greatest of the Carthaginians and one of the greatest generals of antiquity. He was surnamed Barca (the Hebrew *Barak*) or 'Lightning.' When a young man he came into prominence in the sixteenth year of the First Punic War (247 B.C.), when all Sicily, save the fortresses of Drepanum and Lilybæum, had been wrested from Carthage by the Romans. After ravaging the Italian coast, he landed in Sicily, near Panormus, and seized the stronghold of Ercte, a hill of 2000 feet high rising sheer from the sea. Here, with a small band of mercenaries, though he received no aid from his unworthy countrymen, he waged almost daily war with the Romans for three years, and defied every effort to dislodge him. By the spell of his genius he preserved discipline among his unpaid followers, whom he taught to banish their old dread of the Roman veterans, while with his few ships he harassed the Italian shores. In 244 B.C. he occupied Mount Eryx, a hill 2 miles from the coast and a less strong position than Ercte, but one which lay nearer to the besieged cities of Drepanum and Lilybæum. For two years he stood at bay with his handful of men against a Roman army, 'fighting,' says Polybius, 'like a royal eagle, which, grappling with another eagle as noble as himself, stops only to take breath from sheer exhaustion, or to gather fresh strength for the next attack.' The battle of the Ægatian Isles in 241 B.C. ended the First Punic War, and Sicily was yielded to Rome. But Hamilcar marched out from Eryx with all the honours of war. Scarcely had peace been concluded when the Carthaginian mercenaries revolted and were joined by the subject Libyans. Hanno, a personal enemy of Hamilcar, was sent against them. He failed, and the task of saving the state was assigned to Hamilcar, who crushed out the rebellion after a terrible struggle of three years in 238 B.C. In the same year the Romans, in defiance of treaty engagements, seized on the Carthaginian possessions in Corsica. Despite the antagonism of the peace party, headed by the incompetent Hanno, the patriotic or Barcine party, though a minority, obtained the command of an army for Hamilcar, with which he resolved to carry out his master-conception. He proposed to throw Spain into the balance to redress the loss of Sicily. Spain was not only rich in mineral and other wealth; she would form an admirable recruiting-ground. The main defect in the Carthaginian armies hitherto had been the want of an infantry capable of coping on at all equal terms with the legionaries. Such a force Hamilcar determined to create in Spain, whence it could be marched or carried over sea to Italy; in future the war would be waged on Roman soil. In 237 B.C. the general entered Spain, and in nine years built up a new dominion by his military genius, his policy, and the magic of his personality. In 228 B.C. he fell fighting against the tribe of the Vettones. The conceptions of the great Hamilcar were carried out by his mightier son. Unfortunately only a dim light is cast on Hamilcar's marvellous career. What is incontestable is that he was a military genius of the highest order; a statesman as lofty in his conceptions as he was adroit in carrying them out; a patriot whom neither obloquy, ingratitude, nor treachery could alienate from the ignoble state he strove so hard to save. Two men only, it has been truly said, in the whole course of Roman history, seem to have struck the Romans with real terror. These were Hamilcar and his greater son. See Bosworth Smith's *Carthage and the Carthaginians* (1879).

Hamilton, a town of Lanarkshire, on the left bank of the Clyde, 10 miles SE. of Glasgow. The principal edifice is the burgh buildings (1863), with a clock-tower nearly 130 feet high; and there are also the county buildings, large barracks, and a good racecourse. The former manufactures of lace, tamboured bobinette, and cambric have declined; and mining is now the chief industry of the district. Hamilton was made a royal burgh in 1548, and one of the five Falkirk parliamentary burghs in 1832. Pop. (1841) 8724; (1881) 18,517; (1891) 24,863. In 1886 the parliamentary boundary was made coincident with the municipal (extended in 1878).—Hamilton Palace, successor to Cadzow Castle, is the seat of the Duke of Hamilton. Dating partly from 1594, but greatly enlarged in 1705 and 1822, it is a sumptuous classical structure, though its choicest art-collections were

sold in 1882 for nearly £400,000. Within its policies are a superb mausoleum (1852), the ruins of Cadzow Castle, the herd of wild white cattle, and some primeval oaks.

Hamilton, a city of Canada, the chief town in the county of Wentworth, Ontario, is situated on Burlington Bay, at the west end of Lake Ontario, 40 miles by rail SW. of Toronto, and 56 WNW. of Niagara Falls. The business portion lies at the foot of 'The Mountain,' on whose slope many fine residences are embowered among trees and gardens. Trees line the wide, handsome streets; the houses are mostly substantial stone erections, and the court-house and county buildings are among the finest in Canada. The city is an important railway centre, stands in the midst of a populous and highly-cultivated district, at the head of the lake navigation, and is said to possess a larger number of manufactories of iron, cotton, and woollen goods, sewing-machines, boots, glass-ware, &c. than any other town in Canada. Hamilton, which was founded in 1813, is the seat of an Anglican and of a Roman Catholic bishop, and sends two members to the House of Commons and one to the provincial legislature. Pop. (1861) 19,096; (1881) 35,961; (1891) 48,980.

Hamilton, metropolis of the western part of Victoria, on Grange Burn Creek, 224 miles by rail W. of Melbourne. Two pastoral and agricultural exhibitions are held here annually, and two race-meetings. Pop. 3000.

Hamilton, (1) capital of Butler county, Ohio, on the Great Miami River, and on the Miami and Erie Canal, 25 miles by rail N. of Cincinnati. It has a number of paper and flour mills, several foundries, manufactories of farming-implements, breweries, &c. Pop. (1890) 17,565. (2) A post-village of New York, 37 miles SE. of Syracuse, is the seat of Madison University, and of Hamilton Theological Seminary, both Baptist. Pop. 1638.

Hamilton, capital (pop. 2100) of Bermuda (q.v.).

Hamilton, a great historical family, is believed to be of English origin. The pedigree of the family, however, cannot be carried beyond Walter Fitz-Gilbert (son of Gilbert), called Hamilton, who in 1296 held lands in Lanarkshire, and swore fealty to King Edward I. of England as overlord of Scotland, and in 1314 kept the castle of Bothwell, on the Clyde, for the English. His surrender of this strong fortress, and of the English knights and nobles who had fled to it from the field of Bannockburn, was rewarded by King Robert Bruce by grants of the lands and baronies of Cadzow and Machanshire in Clydesdale, Kinneil and Larbert in West Lothian, and other lands forfeited by the Cumyns and other adherents of England. He attained the rank of knighthood, and married Mary, daughter of Sir Adam of Gordon of Huntly. He left two sons. The elder, Sir David Fitz-Walter, was taken prisoner by the English at the battle of Neville's Cross in 1346, founded a chantry in the cathedral of Glasgow in 1361, and appears among the barons in the Scottish parliaments of 1368, 1371, and 1373. His eldest son, Sir David of Hamilton of Cadzow, was the first to assume the surname of Hamilton.

Dukes of Hamilton, &c. The family was only knightly till it was ennobled in its sixth generation, in Sir James of Hamilton of Cadzow, who in 1445 was created Lord Hamilton by a charter which consolidated his whole lands into the lordship of Hamilton, with his manor-place of 'the Orchard,' in the barony of Cadzow, as his chief messuage. In 1460 he founded a college in the university of Glasgow—the first college in Scotland founded by a layman. He also founded and endowed the collegiate church of Hamilton. Allied both by marriage and by descent to the Douglases, he followed their banner in the beginning of their great struggle with the crown. But he forsook them at a critical moment in 1454, and his seasonable loyalty was rewarded by large grants of their forfeited lands. At a later period, after the death of his first wife, when he must have been well advanced in years, he received in marriage the Princess Mary, the eldest daughter of King James II., formerly the wife of Thomas Boyd, the attainted Earl of Arran. His only son by her, James, second Lord Hamilton, was in 1503 made Earl of Arran, and had a grant of that island, the dowry of his mother on her first marriage. After playing an important part in public affairs during the minority of King James V., he died in 1529, being succeeded by the eldest son of his third wife (a niece of Cardinal Beaton), James, second Earl of Arran. The death of King James V. in 1542 left only an infant a few days old between him and the throne. He was at once chosen regent of the kingdom and tutor to the young queen, and declared to be 'second person in the realm.' He held his high offices till 1554, when he resigned them in favour of the queen-mother, Mary of Guise. He received in 1548, from King Henry II. of France, a grant of the duchy of Chatelherault. His eldest son, the Earl of Arran, was proposed at one time as the husband of Queen Mary of Scotland, and at another time as the husband of Queen Elizabeth of England. He was afflicted with madness in 1562, and never recovered his reason, although he lived till 1609. His father, the first Duke of Chatelherault, dying in 1575, the second son, Lord John Hamilton, commendator of Arbroath, became virtual head of the house, and as such was in 1599 created Marquis of Hamilton. He died in 1604, being succeeded by his son James, the second marquis, who in 1619 was created Earl of Cambridge in England, and died in 1625. His eldest son, James, the third marquis, led an army of 6000 men to the support of King Gustavus Adolphus of Sweden in 1631–32, and later acted a conspicuous part in the great contest between King Charles I. and the Scottish Covenanters. That king in 1643 created him Duke of Hamilton, with remainder to the heirs-female of his body, in the event of the death of himself and his brother without male issue. In 1648 he led a Scottish army into England for the king's relief, but was encountered and defeated by Cromwell at Preston, in Lancashire, and, ultimately forced to surrender to the parliamentary forces, was beheaded at Westminster in March 1649. He was succeeded by his brother William who in 1639 had been created Earl of Lanark, and died in 1651 of the wounds which he had received at the battle of Worcester. The duchy of Hamilton now devolved on the eldest daughter of the first duke, Lady Anne, whose husband, Lord William Douglas, Earl of Selkirk, was in 1660 created Duke of Hamilton for life. He died in 1694, and in 1698 the Duchess Anne, who survived till 1716, resigned her titles in the king's hands in favour of her eldest son, James, Earl of Arran, who was anew created Duke of Hamilton, with the precedency of 1643. In 1711 he was created Duke of Brandon in England, but the House of Lords refused him a seat or vote in parliament, on the ground that the crown was disabled by the Act of Union from granting a peerage of Great Britain to any person who was a peer of Scotland before the Union. The duke was killed in a duel in Hyde Park with Lord Mohun in 1712. His grandson, James, the sixth duke, who married the famous beauty, Elizabeth Gunning, was succeeded in 1758 by his eldest son, James George, an infant of three years old. On the death of the Duke of Douglas

in 1761, the male representation of the "red" or Angus branch of the Douglases, with the titles of Marquis of Douglas, Earl of Angus, &c., devolved on the Dukes of Hamilton, as descendants of the Duchess Anne's husband, William, Earl of Selkirk, natural son of the first Marquis of Douglas. Dying in 1769, in his fifteenth year, James George, seventh Duke of Hamilton, was succeeded by his only brother, Douglas, who in 1782 took his seat in parliament as Duke of Brandon, the House of Lords having resolved that the Act of Union did not prevent the crown from making a peer of Scotland a peer of Great Britain. He was succeeded by his uncle, ancestor of the twelfth duke (1845–95). The thirteenth duke, born 1862, is descendant of a third son of the fourth duke.

Dukes of Abercorn, &c. Lord Claud Hamilton, fourth son of the first Duke of Chatelherault, was appointed commendator of the abbey of Paisley in 1553, and created Lord Paisley in 1587. His descendants obtained successively the titles of Lord Abercorn (1603), Earl of Abercorn (1606), Viscount Strabane (1701), Marquis of Abercorn (1790). On the death of the second Duke of Hamilton in 1651, the second Earl of Abercorn claimed the male representation of the House of Hamilton; and in 1861 the second Marquis and tenth Earl of Abercorn (created Duke of Abercorn in 1868) was served heir-male of the first Duke of Chatelherault, in the Sheriff Court of Chancery at Edinburgh, under protest by the Duke of Hamilton, Brandon, and Chatelherault. Dying in 1885, he was succeeded by his son James, the second duke, born in 1838. The Duke of Abercorn is one of three peers who hold peerages in Scotland, in Ireland, and in Great Britain. A cadet of the House of Abercorn, born in 1646, was Count Anthony Hamilton (q.v.).

Other Peerages. The third son of Anne, Duchess of Hamilton, was in 1688 created Earl of Selkirk: this title became extinct in 1885 on the death of the sixth earl.—Lord George Hamilton, fifth son of Duchess Anne, was in 1696 created Earl of Orkney. The sixth earl succeeded in 1877.—A fourth son of Duchess Anne was in 1697 created Earl of Ruglen—a title that became extinct in 1810.—The Earls of Haddington are descended from a younger son of the first ascertained ancestor of the Hamiltons, Sir Walter Fitz-Gilbert.—Sir John Hamilton of Biel was created Lord Belhaven and Stenton. The second lord distinguished himself by his wild but eloquent speeches against the Union. On the death of the fifth lord in 1777 the title and estates became separated; the title became dormant in 1868, but was adjudged in 1875 to the ninth lord.—A descendant of the first Lord Paisley became Viscount Boyne in 1717, and his descendant became in 1866 Baron Brancepeth in the peerage of the United Kingdom.—Another branch of the Hamiltons, settling in Ireland, attained to the dignities of Viscount Claneboy (1622) and Earl of Clanbrassil. The titles became extinct in 1799, but the title of Lord Clanbrassil in the peerage of the United Kingdom was created in 1821.

A *Brefe Account of the Family of Hamilton*, written by Dr James Baillie of Carnbroe during the first half of the 17th century, is preserved among the MSS. in the Advocates' Library at Edinburgh. See Gilbert Burnet's *Memoirs of the Lives and Actions of James and Williams, Dukes of Hamilton and Chatelherault* (1677); Anderson's *Historical and Genealogical Memoirs of the House of Hamilton* (1825); "The Manuscripts of the Duke of Hamilton, K.T.," in part vi. of Appendix to the Eleventh Report of the Historical MSS. Commissioners (1887); and the history of the Earls of Haddington by Sir Wm. Fraser (2 vols. 4to, 1889).

Hamilton, Alexander, one of the greatest of American statesmen, was born 11th January 1757 in the West Indian island of Nevis, the son of a Scotch merchant who had married a young Frenchwoman. His father soon failed in business, and Alexander at the age of twelve had to enter the counting-house of a merchant named Cruger at St Croix. His extraordinary abilities, however, induced some of his friends to procure for him a better education than could be got at home. He was accordingly sent to a grammar-school at Elizabethtown, New Jersey; and in the spring of 1774 he entered King's (now Columbia) College, New York. On the first appearance of disagreement between Great Britain and her colonies, Hamilton, still a collegian and barely eighteen, wrote a series of papers in defence of the rights of the latter, which were at first taken for the production of the eminent statesman Jay, and which secured for the writer the notice and consideration of the popular leaders. On the outbreak of the war he obtained a commission as captain of artillery, saw some active service in New York and New Jersey, and gained the confidence of Washington, who made him his aide-de-camp in 1777, and with whom he acquired the greatest influence as his friend and adviser. In 1781, through hasty temper on both sides, the friendship was broken for a brief period, and Hamilton resigned his appointment on the staff; but he continued with the army and distinguished himself at Yorktown.

In 1780 he married a daughter of General Schuyler, who was a member of a powerful New York family. On the termination of the war he left the service with the rank of colonel, and, betaking himself to legal studies, soon became one of the most eminent lawyers in New York. In 1782 he was returned to congress by the state of New York. But there was as yet no national government nor any power higher than that of the several states, which were now nearly bankrupt; and in 1786 Hamilton took the leading part in the deliberations of the inter-state commercial convention at Annapolis, which prepared the way for the great convention that met at Philadelphia in the following year for the purpose of revising the articles of confederation. There, although his own plan for the formation of an aristocratic republic was set aside, the spirit of his system was to a large extent adopted. But Hamilton's best work for the constitution was done after the convention was dissolved. He conceived and started the famous series of essays which originally appeared in a New York journal, and which were afterwards collected under the title of *The Federalist*. Fifty-one out of the eighty-five essays were the work of Hamilton. They constitute the writings by which he is most widely known; they can scarcely be too highly praised for comprehensiveness, profundity, clearness, and simplicity, and their strength and value have been recognised in Europe as well as in America.

On the establishment of the new government in 1789 with Washington as president, Hamilton was appointed secretary of the treasury. The disorder of the public credit, and the deficiency of official accounts of the state treasury, rendered this office one of peculiar difficulty. In order to re-establish public credit, he carried, in the face of much opposition, a measure for the funding of the domestic debt, founded a national bank, rearranged the system of duties, and altogether showed himself to possess the genius of the great financier. Moreover, he practically organised the administration; and his reports, many of them on subjects outside the immediate scope of his own department, exhibit his profound ability as a statesman. In 1795 he resigned his office, and resumed the practice of law in New York, where he was still constantly consulted by Washington and by his cabinet. He was the

actual leader of the Federal (q.v.) party until his death, and was foremost in the fierce party strife of 1801. His successful efforts to thwart the ambition of his personal rival, Aaron Burr (q.v.), finally involved him in a duel with him. Hamilton had reason to regard the practice of duelling with especial abhorrence, but he appears to have felt under an obligation to accept the challenge; and on the morning of 11th July 1804 they met on the west bank of the Hudson, on the same spot where Hamilton's eldest son had received his death-wound in a duel three years before. Hamilton was mortally wounded, and died the next day, leaving the nation his indignant mourners, and his slayer for the time an exile. Hamilton's errors, like his strength, arose largely from his strong, masterful will and passionate nature. The immediate effects of his brilliant services at a crisis in his country's fate endure to this day; his influence is stamped on every page of the American constitution; and his writings still impress the reader by their vigour, their learning, and the maturity of intellect they display. His works, exclusive of *The Federalist*, were edited by his son, John C. Hamilton (7 vols. 1851), who also published a Life (2 vols. 1834–40). See Riethmüller's eulogistic *Hamilton and his Contemporaries* (Lond. 1864), and Lives by Morse (1876), Shea (1879), Henry Cabot Lodge ('American Statesmen,' 1882), and Sumner (1890); Lodge has also edited Hamilton's *Complete Works* (9 vols. 1885).

Hamilton, ANTHONY, COUNT, a cadet of the Abercorn branch of the Scottish family of Hamilton, was born in Ireland in 1646. At twenty-one he went to France, and got a captain's commission; in 1685 he was captain of Limerick, and fought at the Boyne (1690); thereafter he lived at the court of St Germain-en-Laye, and there he died, 6th August 1720. His writings are full of wit and talent, particularly his *Contes de Féerie* (3 vols. Paris, 1805; Eng. trans. 1849). For his *Mémoires du Comte de Grammont*, see GRAMONT.

Hamilton, ELIZABETH, authoress, was born of a Scottish family at Belfast in 1758, and, after residing in various parts of Scotland and in London, died at Edinburgh, 23d July 1816. Her works comprise *Letters of a Hindoo Rajah* (1796); *Memoirs of Modern Philosophers* (1800); *Letters on Education* (1802); *Life of Agrippina* (1804); *Letters on the Moral and Religious Principle* (1806); and the work by which she is best known *The Cottagers of Glenburnie* (1808), a singularly vivid and life-like representation of humble rural life in Scotland.

Hamilton, EMMA, LADY, was born Amy Lyon or 'Hart,' most likely at Ness, in Cheshire, and on 26th April 1763. Her girlhood was passed at Hawarden. She had had three places in London, had borne two children to a navy captain and a baronet, and had posed as Hygeia in a quack-doctor's 'Temple of Health,' when in 1782 she accepted the protection of the Hon. Charles Greville (1749–1809), to exchange it in 1786 for that of his uncle, Sir William Hamilton (1730–1803). After five years at Naples, in 1791 she was married at Marylebone Church to her elderly ambassador, and, returning to Italy, was straightway admitted to the closest intimacy by Maria Caroline, the queen of Ferdinand I. (q.v.). Her 'eminent services' to the British fleet during 1796–98 in furnishing information and procuring supplies were extolled by Nelson, vaunted by herself, as deserving of peerage and pension; but they were much overrated, where, indeed, not purely imaginary. Nelson had first met her in 1793; and gradually Platonic friendship ripened to guilty passion, until, four months after the trio's return to England, she gave birth to a daughter (1801–81), 'our loved Horatia,' so Nelson writes of her in a holograph letter to 'my own dear Wife, in my eyes and the face of Heaven.' Her credulous husband's death, followed four years later by Nelson's, left Emma mistress of good £2000 a year; but by 1808 she was owing £18,000, and in 1813 was arrested for debt. Next year she escaped to Calais, where she died in penury, 15th January 1815. Her grave is obliterated; but her loveliness lives still in twenty-four portraits by Romney, to whom she was ever the 'divine lady.'

See NELSON; HAMILTON, SIR W.; ROMNEY; the spiteful *Memoirs of Lady Hamilton* (1815; new ed. 1891); Paget's 'Vindication' in *Paradoxes and Puzzles* (1874); Jeaffreson's *Lady Hamilton and Lord Nelson* (1888); and Hilda Gamlin's *Emma Lady Hamilton* (1891).

Hamilton, JAMES, an English merchant, born at London in 1769, who, having been taught German at Hamburg in 1798 by an original method, afterwards exchanged mercantile pursuits for the teaching of languages, and taught with great success in the United States (from 1815) and in England (from 1823). He died at Dublin, 16th September 1829. Hamilton discarded grammar, using in its stead a literal word for word translation, placed immediately below the original, line for line alternately. His own account of it is to be found in *The Principles, Practices, and Results of the Hamiltonian System* (Manchester, 1829).

Hamilton, PATRICK, 'the protomartyr of the Scottish Reformation,' was the son of Sir Patrick Hamilton of Kincavel (Linlithgowshire) and Stanehouse (Lanarkshire) and Catherine Stewart, daughter of Alexander, Duke of Albany, second son of James II. Both his parents were illegitimate. The exact date and place of his birth are unknown. Both are approximately settled, however, by the fact that he graduated as Master of Arts in the university of Paris in 1520—the place of his birth being noted as 'the diocese of Glasgow.' As that degree could not be taken at Paris before the age of twenty-one, we may conjecture that Hamilton was born in the last years of the 15th century. It is also unknown where he received the elements of his education. His university studies seem to have been first conducted at Paris, where, about the time of his residence, the opinions of Luther were already beginning to attract attention. It may be considered the most decisive proof that Hamilton was open to the best lights of the time that on leaving Paris he proceeded to the university of Louvain, where in 1517, under the direction of Erasmus, a college was founded for the study of Latin, Greek, and Hebrew. The foundation of such a college at so early a date in the 16th century was a remarkable innovation in university studies, and the students who availed themselves of it were only such as were in ardent sympathy with the new intellectual and religious ideals of the time. In 1523 we find Hamilton at the university of St Andrews, where his sympathies with Lutheranism soon brought him under the suspicion of the church authorities. To escape the fate which afterwards overtook him he returned to the Continent (1527). After a brief stay at Wittenberg, where he probably saw Luther and Melanchthon, he settled for some months in Marburg, the seat of a university lately founded in the interest of the Reformed doctrines. At Marburg Hamilton wrote (in Latin) the only production of his which has come down to us—a series of theological propositions known as 'Patrick's Places.' In these propositions the main doctrines of the Lutheran reformers are stated with such boldness and precision that Knox has embodied them in his history of the Reformation in Scotland. Hamilton returned to Scotland in the autumn of 1527, and shortly afterwards married. The next year he was summoned

to St Andrews by Archbishop Beaton, uncle of the famous cardinal, and on a renewed charge of heresy was burned at the stake before the gate of St Salvator's College, 29th February 1528. His death probably did more to extend the Reformation in Scotland than even his life could have done. 'The reek of Master Patrick Hamilton,' said one of Beaton's own retainers, 'has infected as many as it did blow upon.'

A peculiar interest has always attached to the name of Patrick Hamilton. His winning personal character, his eagerness for all the best light of his time, his courage, and his early death make him one of the most interesting figures in the religious revolution of Scotland during the 16th century. His martyrdom also gave a distinct impulse to the doctrines for which he died; and Knox himself, in the most emphatic manner, testifies to Hamilton's importance in the history of the Scottish Reformation.

See Professor Lorimer's *Patrick Hamilton, the first Preacher and Martyr of the Scottish Reformation* (1857), and Dr David Laing's edition of Knox's *History of the Reformation in Scotland*.

Hamilton, WILLIAM, a Scotch poet, was born in 1704, most probably at his father's estate of Bangour, near Uphall, Linlithgowshire. He contributed to Ramsay's *Tea-table Miscellany* (1724), and joined in the second Jacobite rising. On its collapse he escaped to France, but was permitted to return in 1749 and to succeed to the family estate the year after. He died at Lyons, 25th March 1754. The first collection of his poems was issued, without his consent, by Foulis of Glasgow in 1748; a fuller collection, with a portrait, appeared under the care of his friends in 1760. One of his poems alone—'The Braes of Yarrow'—will keep his name from ever being forgotten, by the depth and truth of its unsought pathos. See James Paterson, *The Poems and Songs of William Hamilton* (1850).

Hamilton, WILLIAM GERARD (1729-96), earned the epithet of 'single-speech Hamilton' by a speech made in the House of Commons, November 13, 1754, as M.P. for Petersfield in Hants—not *quite* the only speech he ever made in the House. For twenty years he was Chancellor of the Irish Exchequer, and was by some regarded as the author of the letters of Junius (q.v.)

Hamilton, SIR WILLIAM, grandson of the third Duke of Hamilton, was born in 1730, and in 1758, after eleven years' service in the Foot Guards, married a beautiful Pembrokeshire heiress, with £5000 a year, who died in 1782, an only daughter having predeceased her. He was British ambassador at the court of Naples from 1764 till 1800, and in 1772 was made a knight of the Bath. During his residence in Italy he took an active part in the excavation of Herculaneum and Pompeii, and formed a rare collection of antiquities, which was afterwards purchased for the British Museum. He was author of several sumptuous works—*Antiquités Etrusques, Grecques, et Romaines, tirés du cabinet de M. Hamilton* (4 vols. Naples, 1766-67); *Observations on Mount Vesuvius* (1772); *Campi Phlegraei* (Naples, 1776-77), &c. He died 6th April 1803. See HAMILTON, EMMA, LADY.

Hamilton, SIR WILLIAM, of Preston, the most learned and scientific philosopher of the Scottish school, was born March 8, 1788, at Glasgow, where his father, Dr William Hamilton, and his grandfather, Dr Thomas Hamilton, held the chairs of Anatomy and Botany. Though the Hamiltons of Preston, in Haddingtonshire, who were raised to a baronetcy in 1673, had not assumed their title since the death of Sir William Hamilton in November 1688, when his brother and heir, Sir Robert, the Covenanter, refused to take the oath of allegiance, the philosopher made good his claim to represent them, and therefore to be descended from the leader of the Covenanters at Bothwell Bridge. After gaining high distinction, especially in the philosophical classes, at Glasgow, he went in 1809 to Balliol College, Oxford, as a Snell exhibitioner. He graduated with first-class honours in 1810; and it was here that he laid the basis of his vast erudition in medieval and modern, as well as in ancient literature. He left Oxford in 1812, and was called to the Scottish bar in 1813; but he seems never to have had any practice in his profession except what became incumbent on him on being appointed crown-solicitor of the Court of Teinds. In 1820, on the death of Dr Brown, he was an unsuccessful competitor for the chair of Moral Philosophy in Edinburgh; in 1821 he was appointed to the professorship of History.

Hamilton had now reached his thirtieth year without giving to the world any indication of those speculations which he had been silently and slowly maturing. But in 1829 there appeared in the *Edinburgh Review* a critique of Cousin's *Cours de Philosophie* of the previous year, in which was developed that philosopher's doctrine of the Infinite. The critique immediately excited admiration both at home and abroad, and for some years after this Hamilton was a regular contributor to the *Edinburgh Review*. Besides other philosophical articles, two of which, on the Philosophy of Perception and on Recent Publications in Logical Science, are especially celebrated, he contributed several papers on education and university reform. Many of these contributions were translated into German, French, and Italian; and in 1852 they were all edited by Hamilton himself, with notes and appendices, under the title of *Discussions in Philosophy and Literature, Education, and University Reform*. In 1836 Hamilton was elected to the chair of Logic and Metaphysics in Edinburgh. During his first session he delivered a course of lectures on metaphysics, which was followed in the succeeding session by a course on logic; and these two courses he continued to read each alternate year till the close of his life. His influence soon began to show itself in the university among the young men who were attracted thither from different parts of Scotland, and other countries, in many cases chiefly for the sake of hearing Hamilton. Extensive notes of his lectures were taken by his students, and numerous copies of them, transcribed from shorthand reports, were in circulation during the later years of his life. After his death these were published under the editorship of Professors Mansel and Veitch (*Sir William Hamilton's Lectures*, 4 vols. 1859-61). These lectures, which were mostly written during the currency of the sessions in which they were first delivered, want the exactness of thought and expression which mark the works revised by himself for publication; and it is to be regretted that the materials embodied in these volumes were not wrought into another work which Hamilton had planned. This was his edition of the works of Reid, with notes and supplementary dissertations. The general aim of Hamilton's whole philosophy is, in fact, but the special aim of this edition of Reid (1846; additional notes from Hamilton's MSS. by Mansel, 1862). His conviction was that the philosophy of Common Sense (q.v.) represents the highest reaches of human speculation; and he accordingly sought in his annotations of Reid's writings, as in his independent works, to point out the relation of the Scottish philosophy to the systems of other countries, as well as to translate it into a more scientific expression. His labour on Reid was interrupted by ill health. By the paralysis of his

whole right side, though his mind continued unimpaired, his power of work was seriously curtailed during the later years of his life. He nevertheless produced a new edition of Dugald Stewart's works in 1854–55; and he was generally able, with an assistant, to perform the duties of his class till the close of session 1855–56, when his health suddenly became worse, and he died 6th May.

Hamilton's system professes to be merely an explication of the Scottish philosophy; it may, however, be questioned whether all his exegetical skill has vindicated the position claimed for Reid, whether, therefore, it would not have been better for Hamilton had he struck into a separate path. For while his philosophy is distinguished in general from previous Scottish speculations by its more rigorously systematic character, it ventures, as in his doctrine of the conditioned, into wholly new realms of thought. This doctrine, which limits positive thought to the conditioned sphere between the contradictory poles of the infinite and the absolute, attracted more attention than any of his other doctrines, especially after the publication of Mansel's *Bampton Lectures* in 1858 (see CONDITION). Hamilton's contributions to logic may be reduced to the two principles (1) of distinguishing reasoning in the quantity of extension from reasoning in that of comprehension, from which issues his twofold determination of major, minor, and middle terms, and of major and minor premises; and (2) of stating explicitly what is thought implicitly; whence were derived the 'quantification of the predicate,' reduction of the modes of conversion to one, and simplifications of the syllogism.

See Life by Veitch (1869); short monographs by Veitch (1882) and Monck (1881); Seth's *Scottish Philosophy* (new ed. 1891); and SCOTTISH PHILOSOPHY in Vol. IX.

Hamilton, SIR WILLIAM ROWAN, one of the few really great mathematicians of the 19th century, was born in Dublin on August 3–4, 1805. From his infancy he displayed extraordinary talents, and at thirteen had a good knowledge of thirteen languages. Having at an unusually early age taken to the study of mathematics, in his fifteenth year he had mastered thoroughly all the ordinary university course, and commenced original investigations of so promising a kind that Dr Brinkley, himself a very good mathematician, took him under his especial patronage. His earlier essays connected with caustics and contact of curves grew by degrees into an elaborate treatise on the *Theory of Systems of Rays*, published by the Royal Irish Academy in 1828. To this he added various supplements, in the last of which, published in 1833, he predicted the existence of the two kinds of conical refraction the experimental verification of which by Lloyd still forms one of the most convincing proofs of the truth of the Undulatory Theory of Light. The great feature of his *Systems of Rays* is the employment of a single function, upon whose differential coefficients (taken on various hypotheses) the whole of any optical problem is made to depend. He seems to have been led by this to his next great work, *A General Method in Dynamics*, published in the *Philosophical Transactions* for 1834. Here, again, the whole of any dynamical problem is made to depend upon a single function and its differential coefficients. This paper produced a profound sensation, especially among continental mathematicians. Jacobi of Königsberg took up the purely mathematical side of Hamilton's method, and considerably extended it; and of late years the dynamical part has been richly commented on and elaborated by mathematicians of all nations, all uniting in their admiration of the genius displayed in the original papers. For these researches Hamilton was elected an honorary member of the Academy of St Petersburg, a rare and coveted distinction. The principle of *varying action*, which forms the main feature of the memoirs, is hardly capable, at all events in few words, of popular explanation. Among Hamilton's other works, which are very numerous, we may mention particularly a very general *Theorem in the Separation of Symbols in Finite Differences*, his great paper on *Fluctuating Functions*, and his *Examination of Abel's Argument concerning the Impossibility of solving the General Equation of the Fifth Degree.*

We may also particularly allude to his memoir on *Algebra as the Science of Pure Time*, one of the first steps to his grand invention of quaternions. The steps by which he was led to this latter investigation, which will certainly when better known give him even a greater reputation than conical refraction or varying action has done, will be more properly treated under QUATERNIONS. On the latter subject he published in 1853 a large volume of *Lectures*, which, as the unaided work of one man in a few years, has perhaps hardly been surpassed. Another immense volume on the same subject, containing his more recent improvements and extensions of his calculus, as well as a somewhat modified view of the general theory, was published after his death, which took place 2d September 1865.

While yet an undergraduate of Trinity College, Dublin, he was appointed in 1827 successor to Dr Brinkley in the Andrews chair of Astronomy in the university of Dublin, to which is attached the astronomer-royalship of Ireland. This post he held till his death. In 1835 he was knighted on his delivering the address as secretary to the British Association for its Dublin meeting. He occupied for many years the post of president of the Royal Irish Academy; he was an honorary member of most of the great scientific academies of Europe. He held during his life, not in Dublin alone, but in the world of science, a position as merited as it was distinguished. See his Life by Graves (3 vols. 1883-89).

Hamilton Group, a subdivision of the upper Devonian strata of New York.

Hamiltonian System. See HAMILTON (JAMES).

Hamlet, the hero of Shakespeare's greatest tragedy, but whether a figure originally historical, mythological, or partly both, still remains uncertain. The legend of Amleth is first found in the third and fourth books of the Latin history of Denmark by Saxo Grammaticus, written about the end of the 12th century, but first printed at Paris in 1514. According to this version, Gervendill, the governor of Jutland under Rörik, king of Denmark, leaves two sons, Horvendill and Fengo. Horvendill for a brave exploit is rewarded with the hand of Gerutha, Rörik's daughter, who bears him a son, Amleth. Fengo murders his brother, and then prevails upon Gerutha to marry him by persuading her that he had done this crime merely out of love for her. Amleth to save his life feigns madness, and is put to some strange tests by his suspicious uncle. He is finally sent to England with two attendants, bearing a sealed letter instructing the king to put him to death, but he contrives to alter the writing so as to procure for them death, and for himself an honourable reception. He next marries the king's daughter, and returns after a year to Denmark, burns down the banqueting-hall, together with its drunken revellers, and slays Fengo with his own sword. He next revisits England, but, as his father-in-law and Fengo had had a secret agreement that the survivor should avenge the other's death if caused by violence, he is sent for his own doom to Scotland to woo the queen

Hermuthruda, who had killed all former suitors. But the terrible queen herself falls in love with the hero, whose final fate is to fall in battle with Vikleins, the successor of Borik. The interest of the story for students of Shakespeare ends with Saxo's third book, which brings it down to the death of Fengo.

The story of Hamlet was freely translated in the fifth volume of François de Belleforest's *Histoires Tragiques* (1570), and a rough but literal English translation of this exists in a single copy (once Edward Capell's) in the library of Trinity College, Cambridge, entitled *The Hystorie of Hamblet* (London, 1608; reprinted in Collier's 'Shakespeare Library,' 1841). Dr Latham in his *Dissertations on Hamlet* (1872) contends that the hero in Saxo's third book is a different personage from that in the fourth, the former being identical with Olaf Kyrre, the Anlaf Cwiran of the *Saxon Chronicle*, and the Amlaf Cuaran of the *Irish Annals*; the latter, with the Hygelac of Beowulf, and the Chocilaicus of Gregory of Tours. Zinzow, *Die Hamletsage* (1877). For the whole question, see Simrock's *Quellen des Shakespeare* (1870), Moltke's *Shakespeares Hamlet-Quellen* (1881), and Hansen's *Legend of Hamlet* (Chicago, 1887).

Hamley, Sir Edward Bruce, K.C.B., lieutenant-general, was born at Bodmin, 27th April 1824, served in the Crimea, was commandant of the staff college in 1870–77, did delimitation work on the Balkan and Armenian frontiers, and commanded the second division at Tel-el-Kebir in 1882 (where Lord Wolseley and he fell out). In 1885–92 he was Conservative member for Birkenhead; and he died 14th August 1893. He wrote on the war in the Crimea (3d ed. 1891); *Wellington's Career* (1860); *The Operations of War* (1866; 4th ed. 1878); and *Voltaire* (1879); besides several clever novels, and other works. See the Life by Innes Shand (1895).

Hamlin, Hannibal, statesman, was born in Paris, Maine, 27th August 1809, practised law from 1833 to 1848, was speaker of the Maine house of representatives in 1837–40, and was returned to congress in 1842. He sat in the United States senate as a Democrat in 1848–57, when he was elected governor by the Republicans, as opposing the extension of slavery to new territories. He was generally in the senate till his death, 4th July 1891; was vice-president under Lincoln, ambassador to Spain, regent of the Smithsonian Institution, and an LL.D.

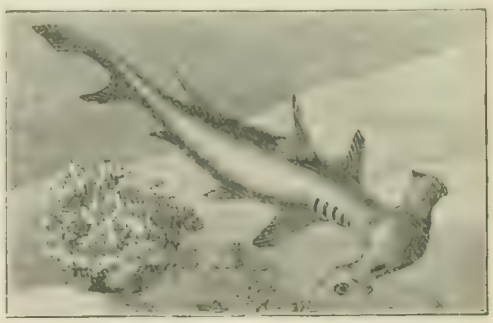
Hamm, a town in Westphalia, on the Lippe, 25 miles NE. of Dortmund by rail, has large metal industries, including iron-foundries, wire-works, manufactories of machines, iron furniture, &c. Pop. (1875) 18,904; (1890) 24,969.

Hammamet, a port of Tunis, on its own gulf, 36 miles SE. of Tunis. Pop. 5000.

Hammer, a tool for beating malleable materials into form or for driving nails, wedges, &c. Often hammers are required of greater weight than a man can wield, and a great variety of power-hammers, masses of iron raised by steam and falling by gravity, are used. The *helve* or *shingling hammer*, used for compressing the mass of iron drawn from the puddling furnace, and the *tilt-hammer*, used in the manufacture of shear-steel, are important examples of such hammers. The first is a heavy bar of cast iron about ten feet long, weighing three or four tons and upwards, to which is attached a head of wrought iron faced with steel, weighing nearly half a ton more. It works upon an axis at the end of the bar farthest from the head, and is raised by cams attached to a heavy wheel set in motion by steam or water power; these cams strike or 'lick' a projection extending beyond the head, and thus raise it about 18 or 20 inches at the rate of from seventy to one hundred times per minute. The tilt-hammer is similar, but much lighter, and is adapted for striking above three hundred blows per minute. In order to attain this velocity a short 'tail' extends with a downward inclination beyond the axis, and the cams strike this downwards, and thus lift the longer arm of the lever to which the head is attached. These, when worked by steam, are, of course, steam-hammers; but when the term steam-hammer is used without qualification, it applies to another and more elaborate machine of very different construction. See Steam Hammer.

Hammerfest, the most northern town of Europe, is situated in 70° 40′ N. lat. and 23° 30′ E. long., on the island of Kvalö, in the Norwegian province of Finmark. It is the rendezvous of the fishing fleets of the Kara Sea and the waters along the Spitzbergen coasts. It imports coal, salt, hemp, flour, &c. in exchange for fish and fish-oil, with some reindeer hides, eider-down, and fox-skins. During the two summer months the sun is continually above the horizon. The winter is mild enough to allow of the fisheries being carried on. The town was burnt, 21st July 1890. Pop. 2289.

Hammer-head, or Hammer-headed Shark (*Zygæna*), a genus of fishes of the family of Sharks, having the general form and characters of the family, but distinguished from all other fishes by the unusual form of the head, which, resembling a double-headed hammer laid flat, extends on both sides to a considerable length, carrying the eyes at the ends of the lateral expansions. The crescent-shaped mouth is below the centre of the head, the nostrils are on the front edge of the head, and the eyes are covered by an eyelid or nictitating membrane. In young specimens the hammer-headed shape is not so well developed as in adults. The hammer-heads bring forth their young alive. In one female, nearly 11 feet long, thirty-seven embryos were found. There are five known species, all of them being most abundant in the tropics. *Z. malleus*, by far the most common form, occurs in nearly all tropical and subtropical seas. In the tropics specimens of this species 'may often be seen ascending from the clear blue depths of the ocean like a great cloud.' Some large ones, one over 13 feet long, have been taken on the British coasts.



Hammer-head (*Zygæna malleus*).

Under side of the head, showing mouth.

Hammer-Purgstall, Joseph, Freiherr von, orientalist, was born at Gratz, 9th July 1774, studied at Vienna, and lived from 1799 to 1806

as interpreter at Constantinople, afterwards becoming a court councillor at Vienna. He was ennobled in 1835 on succeeding by inheritance to the Styrian estates of the Countess von Purgstall, the last of her race. He died at Vienna, 23d November 1856. He had a wide but rather superficial knowledge of Turkish, Arabic, Persian, and other eastern languages, and his industry and zeal did much to push forward the good work of opening up the East to the West. Of his books may be named, in the region of history, *Geschichte der Assassinen* (1818); *Geschichte des Osman. Reichs* (2d ed. 1834-36); *Gemäldesaal Muslim. Herrscher* (1837-39); *Geschichte der Ilchane* (1843); *Gesch. der Chane der Krim* (1856); in that of literary history, *Gesch. der schönen Redekünste Persiens* (1818); *Gesch. der Osman. Dichtkunst* (1836-38); *Litteraturgeschichte der Araber* (1850-57). See Schlottmann's Life (1857).

Hammersmith, a parliamentary borough (since 1885) of Middlesex, is situated on the Thames. A suspension bridge was opened here in 1827, and a new one by Prince Albert Victor in June 1887. The borough returns one member to parliament. Formerly a detached village, Hammersmith is now a large town, and forms part of West London.

Hammock (Spanish *hamaca*, a West Indian word), the apparatus in which a sailor slings his bed. A sailor's hammock consists of a piece of hempen cloth or of strong netting, about 6 feet long and 3 in width, gathered together at each end, and hung to hooks under the deck. Hammocks of netting are often swung from trees in parks and gardens as a pleasant place for idling in fine weather.

Hammond, HENRY, English divine and controversial writer, was born at Chertsey, Surrey, August 18, 1605, and educated at Eton, and Magdalen College, Oxford. In 1633 he was presented to the rectory of Penshurst, in Kent, and ten years later was made archdeacon of Chichester. But his loyal adhesion to the cause of Charles I. cost him his living; yet he officiated as chaplain to the king till his attendants were dismissed in 1647. Hammond then returned to Oxford, and was chosen sub-dean of Christchurch. Deprived by the parliamentary commissioners in 1648, he shortly after retired to Westwood in Worcestershire, where he died April 25, 1660. His celebrated work, the *Paraphrase and Annotations on the New Testament*, was published in 1653 (new ed. 4 vols. 1845). His collected works with biography were published in 4 vols. 1674-84. His *Paænesis* was edited by Manning in 1841. The *Sermons* were reprinted in 1851, the *Minor Theological Works* in 1849, both in the Oxford *Library of Anglo-Catholic Theology*. Bishop Fell's Life (1661) is reprinted in Wordsworth's *Eccles. Biog.*, vol. iv.

Hampden, JOHN, English statesman and patriot, was the eldest son of William Hampden of Hampden, in Buckingham, by Elizabeth, second daughter of Sir Henry Cromwell of Hinchinbrooke, Huntingdonshire, and aunt of Oliver Cromwell. He was born, it is believed, in London, in 1594. He received his early education at the grammar-school of Thame, and proceeded in 1609 to Magdalen College, Oxford. Four years later he became a student of the Inner Temple, London. But his father's death, when he was only three years of age, had left him the master of a considerable estate, and he does not appear to have practised as a barrister. In 1619 he married Elizabeth Symeon, a lady to whom he was much attached; 'on a sudden,' according to Clarendon, 'from a life of great pleasure and license, he retired to extraordinary sobriety and strictness, to a more reserved and melancholy society.' But, although he became in all essentials a Puritan, he never ceased to be a polished country gentleman. In January 1621 he entered parliament as member for the borough of Grampound, a seat which he subsequently exchanged for Wendover, and at once entered the ranks of the parliamentary opposition, of which the recognised leaders were Pym, Eliot, Oliver St John, and Coke. Although he was no orator—it is believed that in the first five parliaments in which he sat he never opened his mouth—his judgment, veracity, and high character secured for him a leading position in the ranks of his party. In 1626 he helped to prepare the charges against Buckingham; the following year, having refused to pay the proportion of the general loan which Charles attempted to raise on his own authority, he was confined in the Gatehouse and subsequently in Hampshire, to be released on Charles finding it necessary to summon a new parliament. His leading political associates were Pym, whom he regarded as his leader in the House of Commons, and Sir John Eliot, who was his personal friend, and after the interests of whose children he looked at the time that their father was in prison. When Charles dissolved parliament in 1629, Hampden retired to his seat in Buckinghamshire, and gave himself up to the pleasures and duties of a rural life, although he neglected neither his friends, his country, nor his favourite political studies. In 1634 his wife, who had borne him nine children, died. The same year Charles resorted to the impost of ship-money, as an evidence of the right which he claimed to tax the country in any way he chose, and although he confined its incidence at first to London and the maritime towns, in 1636 he extended it to inland places. Hampden refused to pay his share of the impost, and in 1637 he was prosecuted before the Court of Exchequer for non-payment. Seven of the twelve judges sided against him, but, as Mr S. R. Gardiner has said, 'the connection between the rights of property and the parliamentary system was firmly established.' The prosecution also made Hampden the most popular man not only in the ranks of the parliamentary opposition but in England—a position which he never lost, although he still played a secondary part to Pym in the House of Commons. He was a member both of the Short Parliament, which opposed Charles and Strafford in connection with the war with Scotland, and of the much more memorable Long Parliament, for which he was returned by the electors both of Wendover and of Buckinghamshire, although he elected to sit for the county. He had indeed not a little to do with giving this remarkable body its character, as before the election took place he rode from county to county exhorting the electors to give their votes to men worthy of their confidence.

Hampden at once took a foremost place in the new House. 'The eyes of all men were fixed upon him,' says Clarendon, 'as their *patriæ pater*, and the pilot that must steer the vessel through the tempests and rocks which threatened it.' He took part in almost all the leading transactions of the Long Parliament, especially in the action which ended in the death of Strafford, although he seems to have been of opinion that proceeding by bill was unnecessary, and that the better course would have been to obtain judgment on the impeachment. Had the abortive negotiations between Charles and the leaders of the opposition come to anything, it is understood that the post of tutor to the Prince of Wales would have been offered to Hampden. Still he had never any faith in the king, and when, through the formation of a party of constitutional royalists in the Commons itself with Lord

Falkland at its head, it seemed not impossible that Charles would be able to crush the liberties of his country. Hampden, like his relative Cromwell, meditated self exile to New England, not for the first time in the course of his public life. In the debate on the address to the king, known as the Grand Remonstrance, it was the calmness of Hampden which prevented the two parties in the House from fighting on its floor. He was one of the five members, Charles's attempt to seize whom, when engaged in the discharge of their parliamentary duties on January 4, 1642, precipitated the Civil War.

When hostilities broke out, Hampden subscribed £2000 to the public service, took a colonel's commission in the parliamentary army, and raised a regiment of infantry in his own county of Buckingham. He attended to his military as to his parliamentary duties with energy and promptitude, and on various occasions, as at the battle of Edgehill and the assault and capture of Reading, he exhibited both personal bravery and generalship. He was, however, placed under Essex, and although he protested against his chief's hesitation, he was powerless to avert its consequences. He heartily approved of, and to a certain extent anticipated, the suggestions made by Cromwell which ultimately resulted in the conversion of the parliamentary forces, under the designation of the 'new model,' into an invincible army. On the 18th June 1643, while endeavouring, on Chalgrove Field, near Thame, to check a marauding force under the command of Prince Rupert, he was struck in the shoulder by two balls. He was able to reach Thame, and there he lingered till the 24th. Hampden has left behind him the reputation of being the most moderate, tactical, urbane, and single minded of the leaders of the Long Parliament, while inferior to none in resolution or sincerity. He showed before his death such capacity both as a statesman and a soldier as to justify Macaulay in predicting that if he had lived he would have been the Washington of England.

The standard biography of Hampden is Lord Nugent's *Memorials of Hampden* (1831). Among the numerous works in which he forms a prominent figure are Clarendon's *History of the Rebellion* 1702 4); S. R. Gardiner's *History of England* and *History of the Great Civil War* (1883 89); and John Forster's *Arrest of the Five Members* 1860 and *Sir John Eliot* (2 vol. 1871). See also Chillern Hills; and for reasons for rejecting the commonly accepted account of his death, see two letters by C. H. Firth in the *Academy*, November 2 9, 1889.

Hampden, Renn Dickson, theologian and bishop, was born in Barbadoes in 1793, studied at Oriel College, Oxford, taking a double first in 1813, and becoming in due course Fellow and tutor of his college. In 1832 his famous Bampton lectures on the *Scholastic Philosophy considered in its Relation to Christian Theology* were by great part of the church considered grievously heretical, and raised a controversy that threatened to break up the Church of England. His successive appointments to the principalship of St Mary's Hall (1833), the chairs of Moral Philosophy (1834) and of Divinity (1836), were denounced alike by the Evangelical and High Church parties, and his elevation to the see of Hereford in 1847 was by them regarded as a death-blow to Trinitarian religion. Yet Bishop Hampden's works may now be regarded as innocent and edifying. After an episcopate of studious quiet, he died at London, 23d April 1868. Of his books may be named his *Work of Christ and the Spirit* (1847), *Lectures on Moral Philosophy* (1856), and *Fathers of Greek Philosophy* (1862). See H. Hampden's *Some Memorials* (1871), and, for the Hampden controversy, Stanley's *Life of Arnold*.

Hampole, Richard Rolle, known as the Hermit of Hampole, was born about 1290 at Thornton in Yorkshire. Sent to Oxford by Neville, archdeacon of Durham, he made great progress in his studies, and at nineteen assumed a hermit's dress, and gave his life entirely to the austerities of religion and to writing, down to his death in 1349, when he was buried in the Cistercian nunnery of Hampole near Doncaster. He wrote religious books both in Latin and in English, and rendered the Psalms into English prose. His great work is *The Pricke of Conscience* (*Stimulus Conscientiæ*), a poem written both in English and Latin. The English version contains 9624 lines on the instability of life, death, purgatory, doomsday, the pains of hell, and the joys of heaven. It was edited by Dr Richard Morris in 1863 for the Philological Society. A small collection of Hampole's prose pieces was edited by the Rev. G. G. Perry for the Early English Text Society in 1866. See also the papers by J. Ullmann in vol. vii., and G. Kribel in vol. viii., of *Englische Studien*, and Horstmann's monograph (1895).

Hampshire, Hants, or, officially, the county of Southampton, a maritime county in the south of England, is bounded W. by Dorset and Wilts, N. by Berks, E. by Surrey and Sussex, and S. by the English Channel. The county, including the Isle of Wight, has an area of 1621 sq. m., or 1,037,764 acres, 700,000 of which are generally under culture. Pop. (1801) 219,290; (1841) 354,682; (1861) 481,815; (1881) 593,465; (1891) 690,086. The surface is diversified by the North and South Downs, the loftiest points being Sidown Hill (940 feet), and, on the Berkshire border, Inkpen Beacon (1011 feet), the highest chalk-down in England. The south-western portion of the county, almost wholly detached from the main portion by the Southampton Water, is occupied mainly by the New Forest, 92,365 acres in extent, the property of the crown. In the south-east and east there are remains of the forests of Bere, Woolmer, and Waltham Chace. The principal rivers are the Test, the Itchen, and the Avon, all flowing southward; the last named forms the western boundary of the New Forest. The climate of the county is in general mild, and favourable to vegetation; indeed, in the south of the Isle of Wight it is believed to be milder than in any other portion of Great Britain. All the usual crops are produced, the wheat being especially good as a rule; hops are cultivated; and the bacon cured here is famous. The Downs afford pasturage for an excellent breed of sheep. Honey is a speciality of the county. The manufactures are inconsiderable, except at Portsmouth and Gosport. Southampton and Portsmouth, both termini of important railways, are the chief centres of trade. The county, exclusive of the parliamentary boroughs of Portsmouth, Southampton, Winchester, and Christchurch, and the Isle of Wight, returns five members for its five divisions —North or Basingstoke, West or Andover, East or Petersfield, South or Fareham, and New Forest. The county council consists of 100 members. Hampshire is wholly in the diocese of Winchester. Towns other than the four boroughs are Aldershot, Alton, Andover, Basingstoke, Bishops Waltham, Bournemouth, Farcham, Gosport, Havant, Lymington, Petersfield, Ringwood, Romsey, and Titchfield. The chief edifices in the county possessing historical or architectural interest are those at Winchester (q.v.); Porchester Castle, at the head of Portsmouth Harbour; Carisbrooke Castle in the Isle of Wight; Calshot and Hurst Castles, now occupied as coastguard stations, erected in the time of Henry VIII.; Netley and Beaulieu Abbeys, and the Priory of St Denis, all in the neighbourhood of Southampton. Hampshire is exceedingly rich in Roman remains. Among

Hampshire's worthies have been Jane Austen, Walter Besant, Charles Dickens, William Gilpin, Keble, Kingsley, Archbishop Warham, Gilbert White, William of Wykeham, and Edward Young. See ISLE OF WIGHT, NEW FOREST; and the histories by Woodward (1861–69) and Shore (1892).

Hampshire Basin. See EOCENE SYSTEM.

Hampstead, a parliamentary borough of Middlesex, is finely situated on a range of hills 4 miles NW. of London. It was formerly famous for its medicinal springs, and is still a favourite place of residence and of holiday resort among Londoners, who are attracted to it by the beauty of its situation and the purity of its air. On the summit of the hill (430 feet), above the village, is the Heath, which affords extensive and pleasant prospects of the surrounding country. A house on the Heath, formerly called the Upper Flask Inn, and now a private residence, was at one time the place of resort of the famous Kit-Cat Club, at which Steele, Addison, Richardson, Walpole, and others used to assemble. Hampstead is associated with many names in literature and art, as those of Pope, Gay, Johnson, Akenside, Joanna Baillie, Byron, Constable, Romney, Coleridge, Keats, Shelley, Leigh Hunt, and Landseer. The borough returns one member. Pop. 68,425. See Howitt's *Northern Heights of London* (1869), and works by Lobley (1889) and Baines (1890).

Hampton, a village of Middlesex, on the Thames, 15 miles SW. of London. In the vicinity are many fine mansions and beautiful villas, including Garrick's villa. Pop. 4776.

HAMPTON COURT PALACE, long a royal residence, and now partially occupied by persons of good family in reduced circumstances, stands about a mile from the village in the midst of grounds that extend to the Thames. The original palace was erected by Cardinal Wolsey, and by him presented (1526) to Henry VIII., who enlarged it and formed around it a royal deer-park. Here Edward VI. was born, his mother, Queen Jane Seymour, died, and Charles I. underwent a portion of his confinement. Here too was held in 1604 the famous conference between the bishops and the Presbyterians. It continued to be a royal residence down to the time of George II. A considerable portion of it was rebuilt by William III., from designs by Wren, and he also laid out the park and gardens in the formal Dutch style. The picture-gallery contains several Italian works, Lely's Beauties of the Court of Charles II., and valuable specimens of Holbein, Kneller, West, &c. The cartoons by Raphael have been removed to the South Kensington Museum. The gardens present a series of raised terraces, formal flower-plots, and long and shady arcades, and have among other attractions a 'maze' or Labyrinth (q.v.). Damage, estimated at £20,000, was caused by fire in November 1886. See Ernest Law, *Hampton Court in Tudor, Stuart, Orange, and Guelph Times* (3 vols. 1885-91).

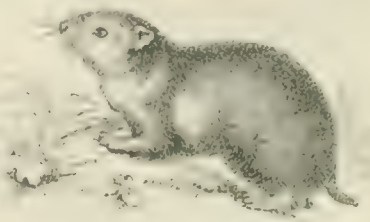
HAMPTON COURT CONFERENCE, a conference which took place at Hampton Court shortly after the accession of James I. to the throne of England, in order to the settlement of ecclesiastical disputes. Of the divines summoned the representatives of the High Church party were more numerous than the Puritans; the Puritans were among the least extreme of their party. Archbishop Whitgift, with eight bishops, six deans, and an archdeacon, appeared on the High Church side; two Oxford professors of divinity, two divines from Cambridge, and along with them Patrick Galloway, minister of Perth, maintained the Puritan cause. On the king's accession the Puritans, entertaining great hopes of release from the rigid enforcement of ceremonies which galled their consciences, and of the reformation of abuses in the church, had addressed a petition to the king, known as the *Millenary Petition*, because it was signed by nearly one thousand ministers in all parts of the country. But the king's intention was not to comply with their wishes, and the Hampton Court Conference seems to have been merely a device for making it appear that their demands had been considered and found unreasonable. On the first day of the conference (12th January 1604) the High Church representatives alone were admitted to the presence of the king, who demanded their opinion, which they gave on the third day after, in favour of the existing system in all the parts complained of. On the 16th of January the Puritans were called to the king's presence, but along with them some of their opponents, when James debated keenly against the Puritans, and, according to his own account of the matter, 'peppered them soundly.' On the 18th of January both parties were called in, and the royal judgment intimated, which was afterwards announced in a proclamation very adverse to the Puritans. See S. R. Gardiner's *History of England*.

Hampton, a town and bathing resort of Virginia, giving name to Hampton Roads, a channel between Chesapeake Bay and the estuary of James River. The town contains a normal institute for coloured pupils. The channel, which is defended by Fortress Monroe, was the scene of several naval actions during the civil war. Pop. 2684.

Hampton, WADE, an American soldier, was born in South Carolina in 1754, served in the revolutionary war under Marion and Sumter, was twice elected to congress, and in 1809 became brigadier-general. In 1813, now a major-general, he made an unsuccessful attempt to invade Canada. He afterwards became wealthy by land speculations, and at his death in 1835 was said to own 3000 slaves.—His grandson, WADE, born in Columbia in 1818, was a state senator when the civil war began. He raised a force of infantry, cavalry, and artillery, known as 'Hampton's Legion,' and served at Bull Run and in the Peninsular campaign. As brigadier-general, he commanded a cavalry force in the Maryland and Pennsylvania campaigns in 1862–63, and was severely wounded at Gettysburg. He received the command of Lee's cavalry in 1864, with the rank of lieutenant-general; and in 1865 he served in South Carolina against Sherman. He was elected governor of his state in 1876, and United States senator in 1878 and 1884.

Hamster (*Cricetus*), a genus of rodent mammals of the family Muridæ, characterised by a stoutish body, short legs and tail, cheek-pouches reaching back almost to the shoulders, five toes on the hind-foot and four toes and a thumb-wart on the fore-foot. Two incisor teeth are present in each jaw (as usual in rodents), the upper ones yellow and undivided; there are three molar teeth on either side in each jaw, which have true roots, the foremost the largest. The stomach has two divisions, and there is a large cæcum. There are nine species, of which the most important is the Common Hamster (*Cricetus vulgaris*), distributed from the Rhine to the middle of Siberia, and from 60° N. lat. to the Caucasus. It is about 1 foot in length (2 inches being occupied by the tail, which is slightly hairy); yellowish-gray above, black below, with several yellowish-white patches on the side, and with white feet. It breeds twice in the year, and from four to sixteen young are produced each time, which are born blind. The males especially are very pugnacious, and will defend themselves courageously to the last gasp. During

the winter the hamster hibernates, living upon its store of food. Each individual makes a burrow for itself, to which there is a vertical entrance and a sloping passage for exit. The sleeping apartment is always separate from the storehouse, of which young hamsters only make one, older ones several.



Hamster (*Cricetus vulgaris*).

It lives upon roots, grain, and fruits, but does not disdain to eat frogs, beetles, or worms. During the summer it lays up a store of grain and pulse, which it carries home during the night in its cheek-pouches. Only the nutritive portions of its booty are stored up, the husks and chaff being rejected; sometimes the amount of its hoard will reach nearly a hundredweight. Hence it is a great pest to the farmers of the countries in which it abounds, and the object of their unceasing hostility. The skins of hamsters are of some value.

Hanaper Office, an office of the Court of Chancery, from which certain writs were formerly issued. The name is derived from the fact that the papers and writs used to be kept in a hamper (*an hanaperium*). The Comptrollers of the Hanaper were abolished in 1842.

Hanau, a town in the Prussian province of Hesse-Nassau, is situated at the confluence of the Kinzig and the Main, 13 miles E. by N. of Frankfort by rail. It is divided into the Old and the New Town; the latter was founded in 1597 by Protestant refugees from Holland and Belgium, who introduced the manufacture of woollen and silk goods, which still flourishes. The town of Hanau stands pre-eminent in Germany for its jewelry and gold and silver wares. Besides these it carries on manufactures of carpets, chocolate, leather, cards, paper, hats, tobacco, and gunpowder, and has breweries and an iron-foundry. Here the brothers Grimm were born. In the neighbourhood is the watering-place of Wilhelmsbad. Hanau dates as a town from 1393. It had a very chequered history during the Thirty Years' War. Near the town was fought one of Napoleon's last battles in Germany, October 30 and 31, 1813, when he defeated the allied Austrians and Bavarians under Wrede. Pop. (1875) 22,269; (1890) 25,029.

Hancock, Winfield Scott, a distinguished American general, was born at Montgomery Square, near Philadelphia, 14th February 1824. His grandfather was a Scotsman, his father an attorney of good position. He graduated at West Point in 1844, served with merit through the war with Mexico, and had reached the rank of captain when the civil war broke out. Commissioned in 1861 brigadier-general of volunteers, he did good service in organising the army of the Potomac, and was prominent in the battles of South Mountain and Antietam; at Fredericksburg, as major-general of volunteers, he led 5000 men to the desperate assault on Marye's Heights through a deadly fire from which less than 3000 came back. In June 1863 he was given the command of the 2d corps. At Gettysburg, Hancock was in command until Meade's arrival; and on 3d July he was severely wounded, but remained on the field until the enemy's last determined assault was repulsed by his corps. In 1864 he was conspicuous in the hard-fought battles of the Wilderness, Spottsylvania, and Cold Harbor; at Spottsylvania he captured nearly an entire division, and carried a salient of field-works on the Confederate centre, afterwards known as the 'bloody angle,' which, with the help of the 6th corps, he held against Lee's desperate assaults. For this, and his services afterwards under Grant, he was created brigadier-general in the regular army, 12th August 1864. His wound now broke out again, and thereafter, while the war continued, his energies were directed mainly to the work of organisation. In 1866 he was promoted to major-general, and assigned to the command of the department of the Missouri, where he was for a time employed against the Indians. He was then transferred to the South, and in 1868 to the division of the Atlantic. To this post, after three years' command in Dakota, he was restored in 1872, and filled it till his death. He was the Democratic candidate for the presidency of the United States in 1880, but was defeated by Garfield (q.v.). He died on Governor's Island, in New York harbour, 9th February 1886. Grant has written, 'Hancock stands the most conspicuous figure of all the general officers who did not exercise a separate command.' McClellan called him 'superb,' and the title stuck to him. He was a brave, fearless soldier, prompt in decision, and skilled to command; but one who would rather lead than send his troops forward, and whose presence in the thickest of the fight won him their confidence. See the Lives by Junkin and Norton (1880), Goodrich (1886), Walker (1890), and the *Reminiscences* of him by his widow (1887).

Hand. The. The genus *Homo*, or Man, was ranked by Cuvier in his classification of mammals as a distinct order, Bimana, in consequence of man being the only animal possessing *two hands*. Recently the tendency has been to revert to the classification of Linnæus, and to place man with all monkeys, lemurs, and bats in the order Primates (see Bimana, Mammalia). At first sight it might be considered that the so-called Quadrumana or four-handed animals (monkeys, &c.) were better equipped than those which possess only two hands, but this is far from being the case. None of the four hands are adapted to the variety of actions which the human hand is capable of performing, and they are all, to some degree, required for support and locomotion; so that, while in the higher

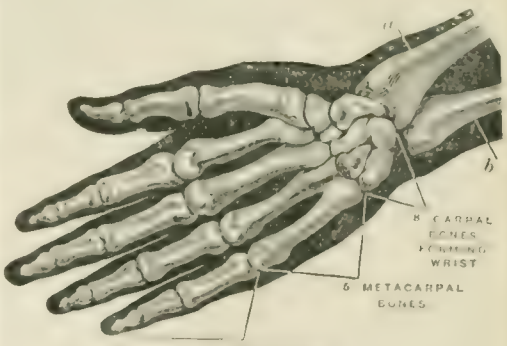


Fig. 1.—Front view of the Bones of right hand
a, radius; b, ulna.

forms of the quadrumana the extremities present an approximation in structure to those of man, in the lower they gradually tend to resemble the ordinary quadrupedal type. 'That,' says Cuvier, 'which constitutes the *hand*, properly so called, is the

faculty of opposing the thumb to the other fingers, so as to seize upon the most minute objects—a faculty which is carried to its highest degree of perfection in man, in whom the whole anterior extremity is free, and can be employed in prehension.' The peculiar prehensile power of the human hand is chiefly dependent upon the length, power, and mobility of the thumb, which can be brought into exact opposition to the extremities of all the fingers, whether separately or grouped together.

The general arrangement of the bones of the hand will be understood by a reference to fig. 1.

In fig. 2 we have a diagram showing the way in which the bones of the hand are arranged. The carpal bones (3 to 10 in the figure) are eight in number, and are arranged in the wrist in two rows. The first or upper row consists practically of three bones (3, 4, 5), the fourth (6) being regarded as belonging to the class of *Sesamoid Bones* (q.v.), and the second row of four bones (7, 8, 9, 10); so that, excluding the pisiform bone (6), the carpal and the tarsal bones correspond in number. As we commonly term the palm the *front* of the hand, the thumb becomes conventionally the *outer*, and the little finger the *inner* digit; but according to the rules of comparative anatomy, and in order to compare the hand and foot, we ought to reverse these terms. The outer (3) of the carpal bones of the first row supports (through the intervention of 7 and 8) the bones of the thumb and forefinger (I and II), and constitutes with them the *outer* division of the hand. The inner (5) of the carpal bones bears the little and the next (the ring) finger (V and IV), and constitutes with them the *inner* division of the hand, while the middle one (4) bears the middle finger (III), and belongs to the *middle* division of the hand. We likewise see from this figure, and also from fig. 1, that the two outer bones (3 and 4) are connected with the radius, while the inner bone (5) is connected (indirectly by a thick ligament) with the ulna.

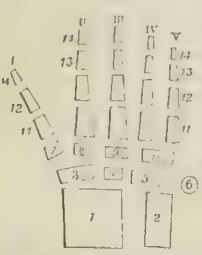

Fig. 2.—Diagram of the Bones of the Hand, with the ends of the Radius and Ulna (after Humphry):

1, end of radius; 2, end of ulna; 3, scaphoid; 4, semilunar; 5, cuneiform; 6, pisiform; 7, trapezium; 8, trapezoid; 9, magnum; 10, unciform; 11, 11, metacarpal bones; 12, 12, first row of phalanges; 13, 13, second row; 14, 14, third row; I, thumb; II, forefinger, &c.; V, little finger.

The carpal bones are so arranged that the carpus presents a dorsal convex surface, upon which the tendons of the extensor muscles of the fingers play, and a palmar concave surface on which the tendons of the flexor muscles lie. The several bones are joined to one another—each bone being united to three or more others—by a large extent of surface, and are girded together by strong ligamentous bands. The wrist is thus as strong as if it had been constructed of one solid piece of bone, while the slight gliding movements which occur between the several bones give it an elasticity which serves to break the shocks that result from falls upon the hand. The uppermost surface of the first row of carpal bones is convex, and this convex surface is received into a wide cup or socket, formed by the lower articular surface of the radius and by a ligament passing from that bone to the ulna. Like the great toe, the thumb has only two phalanges, while each of the other digits has three.

For the different directions in which the arm and hand collectively can be moved, see the description of the construction and movements of the shoulder and elbow joints at ARM. Movements of the forearm and hand, to which there is virtually nothing analogous in the leg, are those of 'pronation and supination.' In *pronation* (derived from *pronus*, 'with the face downwards') we turn the palm of the hand downwards, as in picking up any object from the table; in *supination* (derived from *supinus*, 'with the face upwards'), we turn the palm upwards, as for the purpose of receiving anything that may be placed in it.

These movements of pronation and supination are so important to the usefulness of the hand that we must notice the muscles by which they are chiefly effected. One of these muscles passes from a projecting process on the inner side of the arm-bone at its lower end to the outer edge of the middle of the radius. Its contraction causes the radius to roll over, or in front of, the ulna. It thus pronates the hand, and is called a *pronator* muscle. Another crosses from the front of the lower end of the ulna to the corresponding part of the radius. Its shape and its action are indicated by the name *pronator quadratus*. Another muscle passes from a projecting process on the outer side of the arm-bone and from the outer aspect of the ulna to the outer surface of the radius near its upper part. It runs therefore in an opposite direction to the former muscle, and produces an opposite effect, rolling the radius and the hand back into the position of supination. Hence it is called a *supinator* muscle (see fig. 3). The fourth is a very powerful muscle termed the *Biceps* (q.v.), which not only bends the elbow, but, from the mode in which its tendon is inserted into the inner side of the radius, 'also rotates the radius so as to supinate the hand; and it gives great power to that movement. When we turn a screw, or drive a gimlet, or draw a cork, we always employ the *supinating* movement of the hand for the purpose; and all screws, gimlets, and implements of the like kind are made to turn in a manner suited to that movement of the right hand, because mechanicians have observed that we have more power to supinate the hand than to pronate it.' Supination can only be performed to its full extent by man, and even in man it is not the natural or habitual position; monkeys can partially effect the movement, and in most of the lower animals the part corresponding anatomically to the hand is constantly in a state of pronation.

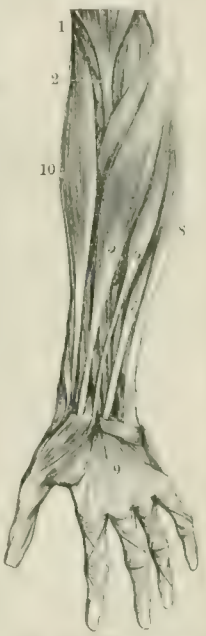

Fig. 3.—The superficial Muscles of the Forearm:

1, biceps; 2, tendon of biceps; 5, the radial flexor of the wrist; 6, the long palmar muscle, spreading out at 9 into the palmar fascia; 8, the ulnar flexor of the wrist; 10, the long supinator muscle.

The movements of which the hand itself, without reference to the arm, are capable, are very numerous, and in this respect differ considerably from the corresponding movements of the foot. Thus we can bend the fingers down upon the palm, or we can extend them beyond the straight line; we can separate them from one another to a considerable extent, and we can close them with considerable force. The wrist and hand are bent forwards or flexed upon the forearm by three muscles which pass downwards from the inner

condyle or expanded end of the humerus, and are termed the *radial flexor*, the *ulnar flexor*, and the *long palmar* muscles. The first two of these muscles are inserted into wrist bones on the radial and ulnar sides respectively, while the third expands into a fan-like *fascia* or membrane in the palm of the hand, and thus serves both to support the skin of the palm and to protect the nerves and vessels which lie below it. Beneath the palmar fascia lie two sets of *flexor* muscles of the fingers, and they present so beautiful a mechanical arrangement as to merit special notice.

The *superficial* or *perforated flexor* muscle passes down the front of the forearm, and divides into four tendons, which become apparent after the removal of the palmar fascia, and are inserted into the second phalanges of the fingers, each tendon splitting at its termination, to give passage to the similar tendons of the *deep* or *perforating flexor* muscle, which passes from the upper part of the ulna to be inserted into the last phalanx of each finger. This arrangement of the tendons of the superficial and deep flexor muscles is shown in fig. 4. To these *flexor* muscles

Fig. 4.

To show the perforation of one of the tendons of the superficial flexor muscle (which is inserted into the second phalanx), in order to allow the corresponding tendon of the deep flexor to pass onwards to be inserted in the last phalanx.

correspond the *common extensor* muscle of the fingers, which, like the flexors, divides into four tendons, one for each finger. Besides these, there is a special *extensor* of the index finger, a series of muscles forming the ball of the thumb, which move that organ in almost every direction, and various small muscles giving lateral and other movements to the fingers.

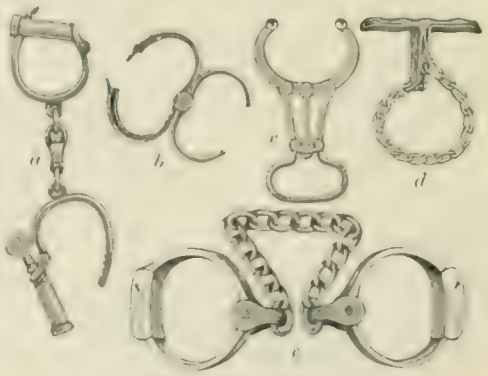
It is sufficient to observe that the hand is very richly supplied with blood-vessels and nerves, without entering into any anatomical details on these points. There is no part of the body where the sense of touch is so acute as at the tips of the fingers; but we defer to the article TOUCH the consideration of the special arrangements which make this part of the hand peculiarly important in relation to our knowledge of external objects.

As a measuring standard for the height of horses a hand is a palm-breadth, assumed to be four inches. For left handedness, &c., see RIGHT AND LEFT HANDEDNESS.

Our notice of the comparative anatomy of the Foot (q.v.) renders it unnecessary to trace the modifications presented in the lower animals by the bones corresponding to those of the human hand, as the carpal and metacarpal bones with their phalanges undergo adaptations of form to meet the individual wants of the animal, very much in the same manner as the tarsal and metatarsal bones and their phalanges. Thus, the reader will readily see that the so-called knee of the horse, for example, is the carpus, and he will have no difficulty in tracing the metacarpal bones and phalanges. See Sir Charles Bell, *The Hand, its Mechanism and Vital Endowments* (Bridgewater Treatise, 1836; 9th ed. 1874).

Handcuffs, the instruments used for securing prisoners under arrest. In the 15th and 16th centuries they are spoken of as *swivels*, *manacles*, and *shackbolts*. Until within the latter half of the 19th century, those in common use seem to have been only of two kinds—viz. the rigid or figure-8 handcuffs, employed chiefly in prisons for the punishment or restraint of refractory or violent prisoners, and the flexible or chain handcuffs used by the police and military when conveying a person in custody from one place to another. With the former the wrists are so confined as to be fixed in one position either in front or behind the body of the prisoner, the latter method being the one generally adopted when they are put on for infraction of prison regulations. This punishment is a much dreaded one, the confinement of the wrists together at the prisoner's back even for a short period being exceedingly irksome and uncomfortable. The chain handcuff, which is in most common use, is made so that, while depriving the prisoner of the free use of his hands and arms, a change in the position of these to some extent is permitted, and the rigidity of the figure-8 handcuffs is avoided. Of recent years several improvements have been made in the construction of the handcuffs. They are much lighter, and many of them are now adjustable (*a* in fig.). By means of a *ratchet* arrangement they are made to fit any size of wrist, and the difficulty which was formerly met by an officer taking two or three pairs of different sizes with him when going a distance to bring a prisoner has thus been overcome. For the removal of gangs of prisoners from one prison to another a long chain is used, running through and connecting the handcuffs by which each prisoner is secured. Gangs of eight or ten men are thus fastened together, the chain passing through a ring fixed on each handcuff, and made fast at both ends by what are known as *end locks*.

In addition to the handcuffs above described there are several appliances, mostly of recent invention, which are employed by the police in securing prisoners, but which are not known among the officers of the law as handcuffs. They



Various forms of Handcuffs

have a variety of names—such as *snaps* (*b* in fig.), *nippers* (*c* in fig.), *twisters* (*d* in fig.), &c. They are distinguished from the handcuffs by the fact that they are intended only for one wrist, the other part or handle being held by the officer conveying the prisoner. They are mostly of American origin, their chief design being to enable an offender to be instantaneously secured, and thus prevent attempts to resist capture. The *snap* is the one most in use in Great Britain among detective officers; the smaller loop is slipped on the wrist of the offender, and the fastening is snapped into place and held in the hand of the detective; in an emergency this instrument is very effective when used as a knuckle-duster. In the United States and the colonies the *nippers* are recognised as the most effectual for

prompt operation; by an ingenious arrangement of the centre-bar, shown in the fig., it can be instantaneously fastened by one hand on the wrist of an offender. The *twister* is now generally forbidden in Great Britain, instances having arisen in which its application has been attended with serious injury to the prisoner; but it is still frequently used in some parts of America and in other countries where open resistance to the law is of more frequent occurrence. It is composed of a chain attached to two handles. The chain is put round the wrist, the handles brought together and twisted till the chain grips tight enough. In cases where prisoners have to be removed who are charged with crimes of a desperate kind, the culprit is occasionally secured by leg-irons (*e* in fig.) in addition to the handcuffs, and these are also used in convict establishments upon prisoners who have shown themselves to be dangerous. The leg-iron is fastened above the ankle and locked by a key.

Handel, GEORGE FREDERICK, born at Halle, in Saxony, at No. 4 of the Grosser Schlamm, February 23, 1685. The German name was Georg Friedrich Händel (pronounced Hendel); but he himself signed G. F. Handel to the end of his life. His father (then sixty-three) was a surgeon; his mother the second wife. His passion and ability for music began from the first, but against his father's will. At seven or eight the boy was placed under Zachau, organist at Halle, and in about a year was writing a regular composition every week, besides playing organ, clavier, violin, and hautboy. In or about 1696 he was sent to the court of Berlin, where he met Ariosti and Buononcini the composers. In 1697 his father died, but his education was carefully continued, and on February 10, 1702, he entered the university of Halle, and in the same year became organist of the church at the Moritzburg there. Before this time he was well known as a musician. In 1703 he went to Hamburg, then one of the most musical towns in Germany. Here he played second violin in the opera orchestra, accompanied on the theatre harpsichord, made all the music and enjoyed all the life possible. Among musical houses which he frequented was that of Sir Cyril Wich, English representative. In Holy week, 1704, he produced his first *Passion*. In December he had a duel with his friend Mattheson, nearly fatal, though the difference was soon adjusted; and in January 1705, *Almira*, his first opera, was brought out, and was followed by *Nero*, *Florindo*, and *Daphne* all in German. He also gave innumerable lessons, and wrote much harpsichord music. In the summer of 1706 he left Hamburg, and in January 1707 we find him at Florence, in April at Rome, and in July back at Florence, producing *Rodrigo*. The first three months of 1708 he spent at Venice, and produced *Agrippina*: thence he went to Rome for another three months, and thence to Naples, possibly till Christmas 1709—the whole journey one continued triumphal progress, both in playing and composition. He then returned to Florence, and finished his visit at Venice in the middle of 1710.

He returned by Halle to Hanover, and was made Kapellmeister, with an income of 1500 crowns, and leave to travel. Thence he went by Düsseldorf to London, where he arrived in November 1710. His first opera, *Rinaldo*, was produced at the Queen's Theatre, Haymarket, February 24, 1711, with prodigious success. After this he returned to Hanover, and remained in Germany till the autumn of 1712, when he went back to London. That winter he produced *Il Pastor Fido* and *Teseo*. The spring of 1713 saw his first composition to English words, the first *Birthday Ode*, and the *Utrecht Te Deum*. During this time he lived chiefly with Lord Burlington at his house in Piccadilly. On August 1, 1714, Queen Anne died, and on September 18 George I. arrived. The operas of this year were *Silla* and *Amadigi*. The king was naturally displeased at Handel's long absence from Hanover, and perhaps at his writing a *Te Deum* for Utrecht; but Handel made his peace by the *Water Music*, written for a royal water-party, August 22, 1715. He received a pension of £200, to which were afterwards added two other amounts of £200 each, giving him a permanent income of £600, representing considerably more than the same sum at present. In July 1716 he accompanied the king to Hanover, and returned with him in the following January. While there he wrote his second German *Passion*. In 1718-19 no operas were performed, and Handel was engaged by the Duke of Chandos to direct the music at his palace at Cannons, near Edgware. Here he wrote the twelve *Chandos Anthems* and two *Te Deums* (in B flat and A), *Esther*, *Acis and Galatea*, and the first set of *Lessons*, containing the 'Harmonious Blacksmith.'

In 1720 the Royal Academy was founded in the Haymarket, by subscription of £50,000, 'to secure a constant supply of operas by Handel, to be performed under his direction.' This was the beginning of the great revolution which for a hundred years and more kept English music, once so strong in its native school, under the dominion of foreigners. As director, Handel had been to Dresden early in 1719, and had engaged Senesino and others. Bach travelled thither to see him, but missed him by one day. The Royal Academy Theatre opened April 2, 1720, and Handel's *Radamisto* was produced. Thirteen other operas are spread over the next eight years—*Muzio Scevola* (Act 3 only composed by him), *Floridante*, *Ottone*, *Flavio*, *Giulio Cesare*, *Tamerlano*, *Rodelinda*, *Scipione*, *Alessandro*, *Admeto*, *Riccardo*, *Siroe*, *Tolomeo*. During this time he was naturalised, February 13, 1726. In June 1727 George II. succeeded to the throne, and as court composer Handel composed *Zadok the Priest*, and three other anthems, for the coronation. On June 1, 1728, the theatre closed, and, the money being all spent, the Royal Academy of Music was at an end. Handel and Heidegger then took the house on their own account, and shortly after Handel set out to find singers in Italy. On June 29 he was at Halle with his mother, then suffering from paralysis, under which she lingered till December 27, 1730. The new venture opened December 2, 1729, with *Lotario*, followed by *Partenope*. The next season began November 3, 1730, and contained the new opera *Poro*: *Ezio* and *Sosarme* followed. This spring saw several revivals of *Esther*, also two of *Acis and Galatea*. The season of 1732-33 brought forward *Orlando*. The speculation, however, was not successful, the quarrels with the singers and rival composers were continual, and the result was the opening of the 'Opera of the Nobility,' to which the whole company had revolted, in Lincoln's Inn Fields, December 29, 1733. The struggle was tremendous. On one side was Handel with his partner; on the other a company of rich and powerful noblemen, with all the composers that could be got together—Buononcini, Porpora, Hasse, and all the great singers. Handel's season began October 30, 1733, and he brought out *Arianna*. His contract for the King's Theatre expired July 6, 1734; then began a series of disasters and worries. The Nobility took the King's Theatre, and Handel was driven first to Lincoln's Inn, and then to Covent Garden, where, in partnership with Rich, he produced six new operas, *Ariodante*, *Alcina*, *Atalanta*, *Giustino*, *Arminio*, *Berenice*, besides reviving many of his old ones. On June 11, 1737, the Nobility retired, with a loss of £12,000, while Handel's losses had been so severe, including £10,000 of funded savings, that he was

obliged to compound with his creditors, and give bills for a large amount. No wonder that the health of even his massive frame broke down: paralysis disabled his right arm, and his mind was for a time seriously disordered. A visit to Aix-la-Chapelle, and the strongest remedies there, however, restored him, and by November 7 he was back in London. This ended his career as composer-manager.

Handel's opera days were now over. True, he wrote a few more for his old partner Heidegger—*Parnasso*, *Serse*, *Imeneo*, and *Deidamia*—but henceforward he was to tread a nobler path, that of the English oratorio, which has rendered him immortal. *Esther* had been composed before 1720, *Deborah* and *Athalia* in 1733, *Alexander's Feast* in 1736, in the very thick of his opera squabbles. Then came the funeral anthem for his friend Queen Caroline, 'The ways of Zion' (1737), itself almost an oratorio, and containing some of his noblest music. *Saul* was produced early in 1739; *Israel in Egypt* followed in three months; then the *Ode for St Cecilia's Day*, November 1739, and *L. Allegro*, February 1740. The *Messiah*, finished September 14, 1741, was produced in Dublin, April 13, 1742. He returned to London shortly after, and produced *Samson* (which he had begun before leaving for Dublin), as the leading work in an oratorio season of twelve nights, in the course of which the *Messiah* was first given in London. The new style told, and he enjoyed a short time of prosperity. In 1743 he had a return of paralysis, and in 1751 we find him at Cheltenham drinking its waters. But nothing interferes with his activity. From 1744 to 1750 oratorio follows oratorio, like huge rocks thrown forth from a crater. The *Dettingen Te Deum* and an anthem, 'The King shall rejoice,' in commemoration of the great victory, were followed by *Joseph*, *Semele*, *Belshazzar*, *Hercules*, *The Occasional Oratorio*, *Judas Maccabæus*, *Alexander Balus*, *Joshua*, *Solomon*, *Susanna*, and *Theodora*. Of these *Judas*, written as a hymn of triumph on the campaign of Culloden, has always been the most popular.

Handel's music had now taken wider possession than ever of the public, and had penetrated to a lower stratum. At the Lenten 'Oratorios' nothing else was done. There, too, were his great organ performances, which were very popular. He was probably not a great pedalist, but the spirit and fire of his playing must have been immense. He has left eighteen organ concertos to testify to it. He composed for all occasions. The *Anthem for the Peace* and the *Fireworks Music* for the public fêtes after the treaty of Aix-la-Chapelle were both his. The Foundling Hospital acquired much wealth through his music, and he himself made money, so that at his death he had the large sum of £20,000 in the funds. Of this £1000 was left to the Royal Society of Musicians.

In the summer of 1750 he went abroad, and again missed Bach, who died July 28. After his return he wrote *Jephthah*, his last oratorio. His eyes had for some time troubled him, and in May 1752 he was couched, but with no success. Henceforward, with some slight glimmering, he was virtually blind; but with the help of his old pupil, John Christopher Smith, he continued his Lenten oratorio-concerts to the end. His last note was probably a pencil quaver, inserted in a quintet in *Jephthah*. He died in his house (now No. 25) in Brook Street, Bond Street, at 8 A.M., Easter Eve, April 14, 1759, aged seventy-four, and was buried in Poet's Corner, Westminster Abbey, 8 P.M., April 20. At this time Haydn was twenty-seven, and Mozart three.

There is something expressly English in Handel's characteristics. His size, his hearty appetite, his vast productiveness, his domineering temper, his humour, his power of business, are all our own. So was his eye to the main chance. When a friend picked out the best pieces in one of his oratorios, he said, 'True, they are the best; but you have forgotten the pieces that are to make the money.' In fact he pre-eminently belongs to England. The practical sense of his music, and its close alliance with the Bible, joined to its lofty imaginativeness, suit the English public. Its sacred character and its independence of the theatre also fall in with our Puritan spirit. Abroad he is little known, and that mostly as a curiosity. But to the great English public he is even still their meat and drink. And yet on how slender a thread does the connection hang! But for the oratorios of the *Messiah* and *Israel in Egypt* Handel's name could hardly have been what it is to us. His operas scarcely lasted beyond their original production. When *Giulio Cesare* was revived in 1787 (the year in which *Don Giovanni* was brought out in Vienna), it had to be enriched by the most favourite songs from the others, to make it go down. The *Messiah*, however, took the English people from the first, and has gone on being performed more and more till now. It must have been heard oftener than any play of Shakespeare's. The revival of *Israel* followed in our own times, though its fame is still incomplete. It is no exaggeration to say that these two works have made Handel's name immortal. In them he fortunately forgot that the house had to be filled; nothing is *ad captandum*—all is pure music. But for the light reflected from them few of his works would have remained to the present day. The bright light cast from these two masterpieces illumines a number of compositions which otherwise would have forever remained in the dark. More than this, there can be no doubt that the enormous spread of music since his day has been very largely due to the popularity of the *Messiah*. Cheap editions of that noble work have always led the van.

It is unnecessary to describe the characteristics of his compositions, because every Briton knows them, or can know them. His plagiarism must be mentioned, though there is no room to deal with both sides of the subject. His habit of using—almost of preferring—ideas from strangers or from his own earlier works is most remarkable. Perhaps this was his own practical way; the work had to be done in the time, and he trusted in himself that all would be right. Perhaps, too, the habit came from a deeper source than mere economy. When writing the Hallelujah Chorus, he looked up like Isaiah in the Temple, and had the same vision. 'I did see,' said he, 'all heaven open before me, and the Great God Himself.' This was the spirit in which he composed; and to one so near the fount of inspiration themes or passages will always be subordinate to the general result, which in Handel's case is pure gold. Sometimes he takes movements bodily ('Egypt was glad'), but he oftener adopts fragments or subjects. His power of transformation is extraordinary. He will take an ordinary theme from some trivial work, and transmute it into an absolutely immortal monument ('Hailstone chorus'). On the other hand his very greatest works are absolutely his own ('Hallelujah;' 'The people shall hear,' &c.). And the remarkable thing is that with all this business-like procedure the effect is so high, characteristic, and appropriate. Beethoven's judgment on him was perfectly sound: 'Handel is the unapproachable master of all masters; go to him and learn to produce great effects with little means.'

Handel's powers of work were enormous. He rarely sketched his pieces, but began the score

at once. Scoring was a light matter in those days, but even so he was very rapid. *Rinaldo* was written in fourteen days, *Tamerlano* in twenty, the *Messiah* in twenty-four, and *Israel* in fifteen.

His face was far nobler than is usually supposed. The portraits are mostly poor, and the gross features they give are part of the inveterate caricature which pursued his figure, his features, and his language through life. Those who want to see him as he was should have a cast of Roubiliac's head in Westminster Abbey, itself taken from a mould, and full of tenderness and dignity. His smile is said by those who had seen it to have been heavenly, 'like the sun breaking through a cloud.' For English biographies read his Memoirs by Mainwaring (1770), and his Life by Rockstro (1883), with a complete list of works and dates. Chrysander's German biography is invaluable, but unfinished (vols. i.–iii. 1856–67). Of the works themselves the best edition is that of Chrysander (1856 *et seq.*); with all possible condensation they fill ninety-eight vols. The majority of the autograph MSS. are at Buckingham Palace; sketches are at Cambridge in the Fitzwilliam.

The first Handel Commemoration performance was held in Westminster Abbey in 1784; Handel Festivals have been held since 1859, usually triennially, at the Crystal Palace. Handel societies for the publication of Handel's works were founded in London in 1843, and Leipzig in 1856, and a Handel and Haydn Society for performances of their works at Boston, U.S., in 1815.

Handfasting (in Old English, merely 'betrothal;' A.S. *handfæstan*, 'to pledge one's hand') was a custom at one time prevalent in Scotland, by which a man and a woman entered into conjugal relations on the strength simply of a verbal contract of marriage. Persons so handfasted were bound to each other for a twelvemonth and a day, after which they could either separate or be formally united in marriage. The custom had its great evils in society, and the clergy, both of the pre-Reformation and the post-Reformation churches, directed many injunctions against it. See Morganatic Marriage.

Handicapping is the term used in various games and sports to denote the placing of competitors, good, bad, and indifferent, on such a footing that all shall have, as nearly as possible, an equal chance of winning. Thus, in Horse-racing (q.v.), when the speed of one horse has been ascertained to be greatly superior to that of another, the swifter of the two, in a handicap race, is made to carry extra weight to an amount that shall be deemed sufficient to reduce its speed to a level with that of its antagonist. In pigeon-shooting from traps, the more skilful the shooter, the farther back has he to stand from the traps. In games such as chess and draughts, certain 'men' are allowed to the inferior player; in billiards, the better of two allows his antagonist a certain number of 'points;' at cricket, an eleven, such as the eleven of All England, will sometimes play against twenty-two others, the competition being at times very close. In swimming and in pedestrianism, the inferior competitors are allowed a certain 'law,' or start; in yachting, the vessel of greater tonnage is handicapped with lesser ones by allowing them extra time for the performance of the race.

Handsel denotes earnest-money, or part-payment, by way of binding a bargain. In some parts of England 'fasten-penny' is used with the same signification. In Scotland handsel popularly signifies the first of a series of transactions in trade, as, for example, the first sale effected in the day or week, or the first of a series of presents. It is likewise employed to signify a present given, generally to a servant or child, on the first Monday in the year—hence called Handsel Monday.

Hand-tree (*Cheirostemon platanoides*), a large tree of the natural order Sterculiaceæ, which receives its name from the peculiar appearance of its flowers. These have no corolla, but a large 5-lobed, angular, coloured calyx—bright red within—from which project the five stamens, united by their filaments into a column, and separating and curving at the summit, where they bear the anthers, so as to have some resemblance to a hand or claw. It is interesting also as being an object of superstitious veneration to the Mexicans, and as being related to the famous Baobab or Monkey-bread (*Adansonia digitata*) of Senegal, Guinea, and other countries of that region of the west coast of Africa.

Handwriting. See Writing, Evidence, Expert.

Hang-chow (*Hang-chau*), the gate of the imperial canal, capital of the Chinese province of Cheh-chiang, and since the Japanese treaty of Shimonoseki (1895) a treaty port, is at the mouth of the Tsien-tang in the Bay of Hang-chow, 110 miles SW. of Shanghai. It was the capital of the Sung empire of southern China previous to its overthrow by the Mongols, and was a splendid city when visited by Marco Polo early in the 14th century. The city, one of the great commercial, religious, and literary centres of China, has clean, well-paved streets and many magnificent temples, is a principal seat of the silk manufacture, of gold and silver work, and is noted for the beauty of its surroundings. From a remote period, many spots in the environs have been the resort of pilgrims; and here several thousands of candidates assemble every year for the public examinations. It was formerly a naval port. The river is subject to a dangerous bore or eagre. Previous to the Tâiping rebellion, the city had some 2,000,000 inhabitants; but it was then (1861) laid in ruins by the rebels, and now contains a population estimated at from 400,000 to 800,000.

Hanging. See Execution, Strangulation.

Hanging Gardens. The Hanging Gardens of Babylon were anciently reckoned among the wonders of the world. Their construction is variously ascribed to Queen Semiramis and to Nebuchadnezzar. Diodorus and Strabo have given descriptions of them. They are said to have formed a square, with an area of nearly four acres, and rose in terraces, supported on masonry arches, to a height of 75 feet. They were irrigated from a reservoir built at the top, to which water was lifted from the Euphrates by a screw. Fountains and banqueting-rooms were distributed throughout the numerous terraces; groves and avenues of trees, as well as parterres of flowers, diversified the scene; whilst the view of the city and neighbourhood was extensive and magnificent.

Hang-nests (*Icteridæ*), a family of finch-like perching birds peculiar to America, and widely distributed over both continents, though most largely represented in the tropical parts of South America. They are often known as American Orioles, a name received because of their brilliant black and yellow colour, not from any connection with the orioles of the Old World. The family includes many well-known birds, such as bob-o-links, cow-birds, grackles, &c., but the name hang-nest is not literally applicable to all, and most perfectly to such genera as Cassicus and Ostinops from tropical South America. The curious purse-like nests woven by many of these birds are often about two feet in length, and have a hole for entrance near the bottom, at one side. One of the best-known species of hang-nest is the Baltimore Oriole (q.v.). The hang-nests are related to the starlings and Weaver-birds (q.v.) of the eastern hemisphere.

Han-hai, an ancient dried-up sea in central Asia, now represented only by Lake Lob nor (q.v.). See ASIA, Vol. I. p. 486.

Hankow (*Han kau*), a river-port of China, in the province of Hu pei, at the junction of the Han River with the Yang tsze, 600 miles W. of Shanghai. Strictly speaking, Hankow is a suburb of the towns of Wu chang and Han yang, the three together forming one huge city. Vessels of large size can reach Hankow, the river being navigable to the city of Ichang, 420 miles higher up. Since 1862 Hankow has been open to foreign trade. The principal article of export is tea, of which one-fourth to one-third out of a total value of two or three millions of pounds exported annually is sent to London. Other articles of export are silk, oil, vegetable tallow, tobacco, hides, nut-galls, coal, musk, and wax. The chief imports are opium, cotton, piece-goods, woollens, metals, sugar, edible seaweed, sapanwood, 'llama' braid, dyes, matches, kerosene oil, and needles. The annual imports sometimes reach a value of over £6,000,000, the exports of over £5,000,000. Of its large trade with the provinces of the interior no statistics are published. Since 1895 a great cotton mill with 700 looms works twenty-two hours daily, making yarn and cloth from native cotton. In 1889 a decree of the emperor authorised the construction of a railway from Hankow to Peking, 700 miles in length. Before the Tâiping rebellion the three cities had a population of over 5,000,000; it is now about 1,700,000, Hankow having 750,000 of these.

Hanley, a town of modern growth, in Staffordshire, in the district known as the Potteries (q.v.), 18 miles N. of Stafford. It manufactures china, earthenware, and encaustic tiles. In the vicinity are coal and iron mines. Hanley was constituted a municipal borough in 1857, and a parliamentary borough, returning one member, in 1885. Pop. (1851) 25,369; (1871) 39,976; (1881) 48,361; (1891) 54,846; of parliamentary borough (including Burslem, q.v.), 86,845.

Hanna, WILLIAM, the biographer of Chalmers, was born in 1808, the son of a theological professor at Belfast. He was educated at the university of Edinburgh, and was ordained in 1835 to the Lanarkshire parish of East Kilbride. He came out at the Disruption, and became in 1850 colleague to Dr Guthrie in Free St John's Church, Edinburgh. He was made D.D. by Edinburgh in 1864, and resigned his church through ill-health in 1867, but survived until 1882. He edited for some years the *North British Review*, and published many theological books, of which perhaps the best known is *Our Lord's Life on Earth* (1869). Well-known works are his *Memoirs of Dr Chalmers*, his father-in-law (4 vols. 1849–52; a fifth, his correspondence, 1853), and *The Letters of Thomas Erskine of Linlathen* (1877–78).

Hannay, JAMES, critic and novelist, was born at Dumfries, 17th February 1827. A few years of boyhood were spent in the navy, from which he was dismissed at eighteen by a court-martial sentence, afterwards quashed as irregular. He early devoted himself to a busy life of letters, finding a favourite pastime in the study of genealogy, heraldry, the classics, and 18th-century English literature. In 1860–64 he edited the *Edinburgh Courant*, and was afterwards British consul at Barcelona, where he died suddenly, 3d January 1873. Of his novels the best are *Singleton Fontenoy* (1850) and *Eustace Conyers* (1855). His *Lectures on Satire and Satirists* (1854) and *Essays from the Quarterly Review* (1861) show wide knowledge and fine literary sense, often expressed in admirably terse and epigrammatic English. Other works were *Three Hundred Years of a Norman House*—the Gurney family (1866), and *Studies on Thackeray* (1869).

Hannibal, a city of Missouri, on the Mississippi, here crossed by an iron railroad bridge, 111 miles by rail NNW. of St Louis. The centre of an important network of railways, it has an extensive trade in lumber, flour, and cattle, and manufactories of flour, tobacco, lime, and railroad cars. There are coal-mines close by. Hannibal is the seat of a Methodist college. Pop. (1890) 12,857.

Hannibal ('the grace of Baal;' cf. the Hanniel of Scripture) was the son of the great Carthaginian general Hamilcar Barca (q.v.), and was born in 247 B.C. It is said that in his ninth year his father led him to an altar and bade him swear eternal enmity to Rome. From the age of nine to eighteen he was trained in war and diplomacy under Hamilcar in Spain; and from his eighteenth to his twenty-fifth year he was the chief agent in carrying out the plans by which his brother-in-law, Hasdrubal, extended and consolidated the Carthaginian dominion in the Peninsula. On the death of Hasdrubal in 221 B.C., the soldiers with one voice chose Hannibal, then in his twenty-sixth year, as their general. Forthwith he crossed the Tagus, and in two years reduced all Spain up to the Ebro, with the exception of the Greek colony of Saguntum. That town, which claimed the protection of Rome, fell in 218 B.C., and the Second Punic war, or as the Romans justly called it, 'the War of Hannibal,' began. Garrisoning Libya with Spaniards, and Spain with Libyans (a precaution against treachery), Hannibal set out on his march for Rome. In the summer of 218 B.C. he left New Carthage with 90,000 foot, 12,000 horse, and 37 elephants, crossed the Pyrenees, and gained the Rhone, where his passage was barred by a host of Gauls. The general thereupon sent part of his troops two days' journey up-stream, with orders to cross the Rhone and fall on the rear of the barbarians. His orders were executed by Hanno, and the passage of the river was safely effected. He crossed the Alps in fifteen days, in the face of obstacles which would have proved insuperable to almost any other commander. His troops, reared under African and Spanish suns, perished in thousands amid ice and snow. The native tribes threatened the annihilation of his force, and were only dispersed by his matchless courage and address. The beasts of burden fell over precipices or stuck fast and were frozen to death. In places, rocks had to be shattered and roads constructed to enable the men to creep round projecting crags. When he gained the valley of Aosta, Hannibal had but 20,000 foot and 6000 horse to attempt the conquest of a power which had lately shown that she could put an army of 170,000 unrivalled soldiers into the field. After allowing his men to recruit in the villages of the friendly Insubres, he overcame the Taurini, besieging and taking Turin, and forced the Ligurian and Celtic tribes on the Upper Po to serve in his army. At the Ticinus, a stream which enters the Po near Pavia, he encountered the Romans under Scipio. The cavalry of both armies joined battle, Hannibal's Numidian horse proved their superiority, and Scipio fell back beyond the Po. The Carthaginians crossed the river, and the first great battle of the campaign was fought in the plain of the Trebia. Placing Mago in ambush with 2000 men, Hannibal enticed the Romans across the stream. His light troops retired before the legionaries, and as Scipio was pressing on to fancied victory he was taken in flank by the terrible Numidian horse, Mago came down in the rear, and the 40,000 men of the consular army were either cut to pieces or scattered in flight. Wintering in the valley of the Po, in the early spring Hannibal crossed the Apennines and pushed through a region of lakes, flooded by the melting of the snows, to Fæsulæ. The beasts of burden perished in vast numbers amid the morasses; the Gauls, disheartened by

the perils of the journey, had to be driven forward by Mago's horsemen, and the general lost an eye. Quitting Fæsulæ, Hannibal wasted Etruria with fire and sword, and marched towards Rome, leaving behind him two consular armies of 60,000 men. He awaited the consul Flaminius by the Lake Trasimene, where the hills, retiring in a semicircle from the shore, enclose a plain entered by two narrow passes. Concealing the main body of his army amid the hills, he placed his Numidians in ambush at the pass by which the Romans must enter; while he stationed part of his infantry in a conspicuous position near the other defile. The Romans pushed into the valley; the pass in their rear was secured by the Carthaginians who had lain in ambush; Hannibal's men charged from the heights, and the army of Flaminius was annihilated. Six thousand infantry cut their way through the farther pass, but these were overtaken by the horse under Maherbal and forced to yield on the following day.

After recruiting his men in the champaign country of Picenum, where the Numidian horses, we are told, were groomed with old Italian wine, Hannibal marched through Apulia and ravaged Campania, dogged by the dictator Quintus Fabius Maximus, whom he vainly endeavoured to entice into an engagement. He wintered at Gerontium, and in the spring took up a position at Cannæ on the Aufidus. A Roman army of 80,000 men, under the consuls L. Æmilius Paulus and P. Terentius Varro, marched against him. Hannibal flung his troops (he had but 30,000) into a space enclosed on the rear and wings by a loop of the river. He placed his Spanish infantry in the centre, with the African foot on either flank. His Numidian horse, now reduced to 2000 men, he posted on the right wing; while Hasdrubal, with 8000 heavy cavalry, was opposed to the Roman cavalry on the left. The legionaries pressed into the loop, and Hannibal drew back his centre before them. Hasdrubal on the left broke the Roman cavalry, swept round to the left wing of the Romans, drove the second detachment of Roman horse into flight, and then came thundering in the rear of the legionaries. The Libyans, who had by the general's orders fallen back as the Romans pressed after the retiring Spanish infantry, now closed on the enemy's flanks. Packed together so closely that they could not use their weapons, assailed in front, flank, and rear, the legionaries were hewn down through eight hours of carnage till 50,000 lay dead on the field. The battle became a butchery. Nearly 20,000 men were taken prisoners. The consul Paulus, the proconsul Servilius, the master of the horse Minucius, 21 military tribunes, and 60 senators lay amid the slain. On his side Hannibal lost but 5700 men. 'Send me on with the horse, general,' said Maherbal, 'and in five days thou shalt sup in the Capitol.'

But the general was wiser than the fiery captain of the horse. It has been common to censure Hannibal for neglecting to march on Rome after the battle of Cannæ. But his dazzling triumph did not for a moment unsettle his clear judgment. He knew that his forces were unequal to the task of storming a walled city garrisoned by a population of fighting men. An attack which he had made on Spoletium had proved the inadequacy of the small Carthaginian army to carry a strongly fortified town. Had he followed the advice of Maherbal, he would, in all likelihood, have dashed his army to pieces against the walls of Rome. His aim was to destroy the common oppressor by raising the Italian allies against her; and the hope was partly justified by the revolt of Lucania and Bruttium, Samnium and Apulia. The soundness of judgment, the patience and self-control which he evinced in this hour of intoxicating success are hardly less marvellous than the genius by which the success had been won. After the battle of Cannæ the character of the war changes. Hitherto Hannibal had swept everything before him. Rivers and mountains and morasses had been powerless to thwart his progress. Army after army, vastly superior in numbers and composed of the best fighting men the ancient world ever saw, had come against him to be broken, scattered, and destroyed. His career through Italy had been, in the words of Horace, as the rush of the flames through a forest of pines. But after Cannæ the tide turned. His niggardly, short-sighted countrymen denied him the support without which success was impossible. As his veterans were lost to him he had no means of filling their places, while the Romans could put army after army into the field. But through the long years during which he maintained a hopeless struggle in Italy he was never defeated. Nor did one of his veterans desert him; never was there a murmur of disaffection in his camp. It has been well said that his victories over his motley followers were hardly less wonderful than his victories over nature and over Rome.

Hannibal spent the winter of 216–215 B.C. at Capua, where his men are said to have been demoralised by luxurious living. When he again took the field the Romans wisely avoided a pitched battle, though the Carthaginians overran Italy, capturing Locri, Thurii, Metapontum, Tarentum, and other towns. In 211 B.C. he marched on Rome, rode up to the Colline gate, and, it is said, flung his spear over the walls. But the fall of Capua smote the Italian allies with dismay, and ruined his hopes of recruiting his ever-diminishing forces from their ranks. In 210 B.C. he overcame the prætor Fulvius at Herdonea, and in the following year gained two battles in Apulia. Thereafter, he fell upon the consuls Crispinus and Marcellus, both of whom were slain and their forces routed, while he almost annihilated the Roman army which was besieging Locri. In 207 B.C. his brother Hasdrubal marched from Spain to his aid, but was surprised, defeated, and slain at the Metaurus by the consul Nero. By the barbarous commands of Nero, Hasdrubal's head was flung into the camp of Hannibal, who had been till then in ignorance of his brother's doom. The battle of the Metaurus sealed the fate of 'the lion's brood'—of the great house of Hamilcar. But for four years Hannibal stood at bay in the hill-country of Bruttium, defying with his thinned army every general who was sent against him, till in 202 B.C., after an absence of fifteen years, he was recalled to Africa to repel the Roman invasion. In the same year he met Scipio at Zama; his raw levies fled, and in part went over to the enemy; his veterans were cut to pieces where they stood, and Carthage was at the mercy of Rome. So ended the Second Punic war—the war, as Arnold so truly said, of a man with a nation, and the war which is perhaps the most wonderful in all history. Three hundred thousand Italians had fallen, and three hundred towns had been destroyed in the struggle.

Peace being made, Hannibal turned his genius to political toils. He amended the constitution, cut down the power of the ignoble oligarchy, checked corruption, and placed the city's finances on a sounder footing. The enemies whom he made by his reforms denounced him to the Romans, and the Romans demanded that he should be surrendered into their hands. Setting out as a voluntary exile, Hannibal visited Tyre, the mother-city of Carthage, and then betook himself to the court of Antiochus at Ephesus. He was well received by the king, who nevertheless rejected his advice to carry the war with Rome into Italy. On the conclusion of peace, to avoid being given up to the

Romans, he repaired to Prusias, king of Bithynia, for whom he gained a naval victory over the king of Pergamus. The Romans again demanding that he should be surrendered, he baffled his enemies by taking poison, which, we are told, he carried about with him in a ring, and died at Libyssa about the year 183 B.C.

In judging of the character and achievements of Hannibal, it must never be forgotten that for all that we know of him we are indebted to his implacable enemies. No Carthaginian record of that astounding career has come down to us. The Romans did all that unscrupulous malignity can to blacken the fame and belittle the deeds of the most terrible of their foes. Yet, though calumny has done its bitterest against him, Hannibal not only dazzles the imagination but takes captive the heart. He stands out as the incarnation of magnanimity and patriotism and self-sacrificing heroism, no less than of incomparable military genius. Napoleon, the only general who could plausibly challenge the Carthaginian's supremacy, had throughout the greater part of his career an immense superiority to his adversaries in the quality of the forces which he wielded. He had the enthusiasm of the Revolution behind him, and he was unhampered by authorities at home. Hannibal, on the contrary, saw his plans thwarted and finally wrecked by the sordid merchant-nobles of the city he strove so hard to save. He had not, like Alexander, to lead picked troops against effeminate Asiatics. He had to mould his little army out of raw and barbarous levies. He had no reinforcements to fall back on. With a motley army of Libyans, Gauls, and Spaniards he had to encounter a nation in arms a nation of the stoutest and most highly-trained warriors of ancient times. There is not in all history so wonderful an example of what a single man of genius may achieve against the most tremendous odds as the story of the Phœnician hero the greatest captain that the world has seen. See Bosworth Smith's *Carthage and the Carthaginians* (1879); Hennebert's *Histoire d'Annibal* (1870-92); Dodge's *Hannibal* (1891); and works cited at CARTHAGE.

Hannington, JAMES, first Bishop of Eastern Equatorial Africa, born 3d September 1847, at Hurstpierpoint in Sussex, became a student of St Mary Hall, Oxford, in 1868, and was ordained in 1873. In 1882, after seven years' earnest labour in his native parish, he volunteered for missionary work in Africa, and was sent out by the Church Missionary Society to reinforce their missionaries in Uganda. But his health broke down when he reached Kagei, on the south shore of Victoria Nyanza, and he was obliged to return home to England. His health improving, he was, on 24th June 1884, consecrated Bishop of Eastern Equatorial Africa, and in the following January entered his new diocese, taking up his quarters at Frere Town, near Mombasa. In July 1885 he started once again for the interior, the object of his journey being to reach the mission-station of Rubaga, in Uganda. But, after successfully surmounting the difficulties and dangers of the road through the land of the Masai, he was slain by order of Mwanga, king of Uganda, on 29th October 1885, at a place not far from the right bank of the Nile. See his Life by Dawson (1887) and his *Last Journals* (edited in 1888).

Hanno, a name borne by a number of Carthaginian admirals and soldiers, one of whom was defeated by the Romans in the sea-fight of Ecnomus in 256 B.C. Another Hanno, surnamed the Great, was the leader of the peace party who opposed the patriotic party headed by Hamilcar Barca, during the interval between the First and the Second Punic war. When the Carthaginian mercenaries revolted in 241 B.C. Hanno was appointed to reduce them to submission. He proved a thoroughly incapable general, and the task in which he had failed was discharged by Hamilcar Barca.

Hanno, a king or magistrate of Carthage who undertook a celebrated voyage of discovery along the west coast of Africa. His expedition is said to have consisted of sixty ships; he founded numerous colonies or trading-stations, and proceeded as far south as a point that has been variously identified with places between Cape Nun and the Bight of Benin. On his return to Carthage he inscribed an account of his voyage on a tablet, and placed it in the temple of Moloch. It seems to have been written in the Punic language; the version of it which remains, entitled the *Periplus of Hanno*, is only a Greek translation. The date of the voyage has been assigned to different periods between 570 B.C. and 470 B.C., and the identification of the author of it has been also a subject for dispute. For a full discussion consult Dodwell's Dissertations, prefixed to Hudson's *Geog. Vet. Scriptores* (1698); Bougainville's, Vivien de St Martin's, and Tauxier's Essays, Falconer's English translation (1797), and Meu's *Mémoire sur le Périple d'Hannon* (1885).

Ha-noi, the capital of Tong-king, and headquarters of the French administration, on the left bank of the Song-coi or Red River, 80 miles in a direct line from the sea. The commercial city has a river-front of a mile and a half; the citadel behind contains within its walls most of the official buildings. Embroidery and work in mother-of-pearl are the chief local industries. Pop. 100,000.

Hanover (Ger. *Hannover*), formerly a kingdom of northern Germany, but since 1866 incorporated with Prussia. Area of the Prussian province, 14,833 sq. m., or nearly twice the size of Wales; pop. (1871) 1,963,080; (1885) 2,172,702; (1890) 2,278,361, mainly Lutherans, with 280,000 Catholics, and 16,000 Jews. Except in the south, where the Harz Mountains (q.v.) attain a maximum altitude in Hanover of 3037 feet, the surface belongs to the great north German plain, and is diversified by moors and heaths, notably the extensive Lüneburg Heath. It is watered by the Elbe, Weser, Ems, and their tributaries. The people carry on mining in the Harz, cattle-breeding on the marshes and heaths, agriculture in the more fertile regions, and seafaring pursuits on the coast. The weaving of linen, cloth, and cotton, the working of iron and other metals, glass, paper, and pottery making, and bleaching, count amongst the more important industries. The mining products are very various, and include iron, silver, zinc, lead, copper, coal, salt, petroleum, and turf. Bees are kept in the Lüneburg Heath; Norderney and Borkum (islands) are much frequented as seaside resorts. Göttingen is the seat of a university, and the capital is Hanover (q.v.). See also PRUSSIA, GERMANY.

The people of the north-eastern and central provinces are mostly Saxons; those on the coast are of Frisian origin; those on the west of the Ems, Dutch; and those in the southern provinces, Thuringians and Franconians. Platt-Deutsch, or Low German, is commonly spoken in the rural districts; but High German is the language of the educated and higher classes, and is spoken with more purity than in any other part of the empire.

History. Hanover was occupied in remote ages by Saxon tribes, who, after an obstinate resistance, submitted to Charlemagne and embraced Christianity. In the time of Louis the German it was incorporated in the duchy of Saxony. In 951 the Emperor Otho I. bestowed it on Hermann Billing; on the extinction of his family in 1106 it fell to

Lothaire of Supplinburg. By the marriage of his daughter to Henry the Proud of Bavaria, the duchy passed to the Guelphs. Henry the Lion, son of Henry the Proud, did much to advance the civilisation of his subjects by conferring rights and privileges upon various towns which had advocated his cause; but, when he fell under the ban of the empire, a period of anarchy and confusion succeeded, which at first threatened the ruin of the country. When, however, in 1180 Henry was deprived of the duchy of Saxony, he was allowed to retain his hereditary lands of Brunswick and Lüneburg. From this time down to the 16th century the history of Hanover is inseparable from that of Brunswick (q.v.).

The history of Hanover as a modern state begins with the foundation of the line of Brunswick-Lüneburg by William, who, in the partition which he and his elder brother Henry (founder of the Brunswick house, extinct in 1884) made of the dominions of their father, Ernest I., obtained in 1569 the duchies of Lüneburg and Celle (Zell). William died in 1592, leaving seven sons, of whom four successively ruled over the land. Of the seven only one (George) married. His eldest son, Christian Lewis, in accordance with a family compact, took (1648) as his portion of the inheritance Lüneburg, Grubenhagen, Diepholz, and Hoya, with Celle for his residence; while his next brother, George William, obtained Kalenberg and Göttingen, with Hanover for his residence. Thus originated the lines of Celle and Hanover. Christian Lewis set himself the task of raising his country from the miseries it had endured in the Thirty Years' War. After his death in 1665 his brother George William exchanged his own duchy for that of Celle, leaving Hanover to a younger brother, John Frederick. George William, as Duke of Celle, deserves notice for his warlike and active administration: he sent auxiliaries to Venice to aid the republic against the Turks; co-operated with the Duke of Brunswick to reduce his insurgent capital; entered into an alliance with the emperor against France and Sweden; sent an army into Hungary to resist the Turks; and in 1688 lent troops and money to William of Orange against James II. of England. John Frederick of Hanover entertained a great admiration for the French, and aped the magnificence of the court of Versailles. He was succeeded by his brother, Ernest Augustus (another son of George), in 1679. Thus the Hanoverian territories were again united under one head, in George Lewis, son of Ernest Augustus, who succeeded to the duchy of Hanover in 1698, and to that of Celle in 1705. The mother of George Lewis was Sophia, daughter of Frederick V. of the Palatinate and of Elizabeth, daughter of James I. of England. In 1714 George Lewis became king of England as George I. His father, Ernest Augustus, had in 1692 been invested with the dignity of the newly-created ninth electorate.

Under George Lewis as king of England and second elector of Hanover or Brunswick-Lüneburg, a brighter epoch opened to the Hanoverians; they were relieved from the burden of maintaining the ducal court and household, and the revenues of the crown were thenceforth appropriated to the general purposes of the state. The government was left in the hands of a viceroy and the confidential council. Bremen and Verden were obtained in this reign by purchase from Sweden (1719). George II., who succeeded in 1727, like his father spared the revenues of Hanover at the expense of those of England. In his character of elector, he espoused the cause of Maria Theresa in the Austrian war of succession; but in the Seven Years' War Hanover sided with Prussia against Austria and France, and suffered severely, especially by the capitulation of Closter-Seven (1757). This king founded the university of Göttingen in 1734–37. The peace which prevailed during the first thirty years of the reign of George III., who succeeded on the death of his grandfather in 1760, and who alone of the four Georges never visited his German dominions, proved a veritable godsend to Hanover, which also profited by the increased English and American trade. In 1793 Hanoverian troops took part in the wars against the French Republic, the expenses of their maintenance being defrayed by England. But in 1801 Prussia, refusing to acknowledge the neutrality of Hanover, threw troops into the electorate, and maintained her military occupancy for a year. In 1803, when war was renewed between England and France, an army under Mortier intimidated the Hanoverians to such an extent that, without striking a blow, they pledged themselves to abstain from serving against France, to disband their army, to give up their arms and horses to the enemy, and to submit to receive a French corps of occupation 30,000 strong. In 1807 Napoleon appropriated a portion of the electorate to complete the newly-formed kingdom of Westphalia, which in 1810 received the whole of the Hanoverian territory. On the successful termination of the war of liberation, Hanover was created a kingdom in 1815. In 1819 a new constitution was granted, which made provision for the election of two representative chambers; but it only lasted until 1833. Nevertheless, the general disaffection and distrust had risen to the highest pitch when William IV. ascended the throne; and in 1831 the prime-minister, Count Münster, who had long been obnoxious to the mass of the people, was dismissed, and the Duke of Cambridge, son of George III., who had since 1816 acted as governor-general, was invested with the title of viceroy. George IV. was of course also king of Hanover; but on the death of William IV. in 1837 Hanover was separated from England and given to the next male heir, Ernest Augustus, Duke of Cumberland, the fifth son of George III. (1771–1851). This prince initiated a policy in all respects reactionary; but in 1848 he did so far yield to the storm as to just save his throne by the unwilling concession of liberal reforms. A famous incident in the struggle was the protest and expulsion in 1837 of seven Göttingen professors (see GÖTTINGEN). His son, the blind George V. (1819–78), who succeeded in 1851, held very extreme views in regard to the kingly power and the claims of the aristocracy, and for fifteen years he struggled against the will of the people in defence of his absolutist ideas. In 1866 Hanover took part with Austria, and at Langensalza (27th June) the army, after a successful defence, was surrounded and capitulated; Hanover was then occupied by Prussia, and finally annexed. George V. until his death, and since then his son, Ernest Augustus, Duke of Cumberland (b. 1845), still maintaining their claim to the Hanoverian throne, were compelled to live in banishment. The incorporation with Prussia was viewed with anything but general favour; Professor Ewald, for instance, to the day of his death, being a staunch adherent of the exiled house. In 1868 the so-called *Welfenfonds* ('Guelph-fund')—the private property of the king of Hanover—was sequestrated by Prussia, and has subsequently been managed by a commission. Prince Bismarck's enemies were wont to affirm that this fund—called by them *Reptilienfonds* ('Reptile-fund')—was largely used for bribing newspapers to support the government policy.

See *Gemeindelexikon für die Provinz Hannover* (Berl. 1887); and works by J. Meyer (1886), Grotefend (1857), and Meding (1881–84).

Hanover (Ger. *Hannover*), formerly capital of the kingdom, now chief town of the province of

Hanover, is situated on a sub-tributary of the Weser, 78 miles SE. of Bremen, 112 S. of Hamburg, and 158 W. of Berlin. It consists of the old town, with narrow streets and medieval houses, and the handsome modern town, lying north, east, and south-east of the older portion. The most interesting buildings are the town-hall, founded in 1439, with antique sculpture and fine frescoes; the royal library, with 170,000 volumes and 4000 MSS., incunabula, archives, and valuable state papers; the theatre, one of the largest and dramatically one of the most important in Germany; the palace of King Ernest Augustus, with a library and collections of coins, arms, and engravings; the museum, with good natural history and art collections; the royal state palace; the Kestner Museum, with Etruscan, Greek, and Roman antiquities and a collection of engravings (120,000); the polytechnic school, formerly a ducal castle; the castle church, in which are preserved a collection of medieval church utensils, relics, many of them brought from Palestine by Henry the Lion in 1172, and an altar-piece by L. Cranach; the 14th-century 'market' church, with stained glass and monuments; and the 'new town' church, with an elegant tower and the tomb of Leibnitz, who died in Hanover. The magnificent railway station, perhaps the finest in Germany, should also be mentioned. Hanover was the first place in Germany that was lighted with gas (1826). In the immediate vicinity of the town is the royal palace of Herrenhausen, whose beautiful grounds and gardens are open to the public.

Since Hanover became a centre of the North German railway system, its manufactures have greatly increased in importance. Amongst the foremost industries are railway repair shops, iron-founding, typefounding, the manufacture of pianofortes, india-rubber goods, tobacco, linen, sugar, chocolate, hardware, brewing, and distilling. Pop. (1871) 87,641; (1880) 122,843; (1890) 163,153. Hanover is the birthplace of the brothers Schlegel; Iffland the actor and dramatist; Louisa, queen of Prussia; Sir William Herschel; and the historian Pertz. In the 14th century the town was a member of the Hanseatic League, and in the 15th it had a prosperous trade, which, however, declined considerably during the troublous times of the Reformation. From about 1640 its importance rested mainly on the fact that it was the residence of the duke and elector. The revival of its industry within recent years has also brought with it a revival of commerce. See works by Hartmann (1880) and Kalbe (1886).

Hanover, a post village of New Hampshire, pleasantly situated near the east bank of the Connecticut, 55 miles NW. of Concord. It is the seat of Dartmouth College (1770), which is richly endowed, and possesses a library of 65,000 volumes. It includes a medical school and the state college of agriculture and mechanic arts. Pop. 1134.

Hansard, a well-known name in connection with the printing of the British parliamentary records. Luke Hansard, born in 1752 at Norwich, came to London in 1770, and worked for some years as compositor in the office of Hughes, printer to the House of Commons, whom in 1798 he succeeded as sole proprietor of the business. He died in 1828; but his descendants continued to print the parliamentary reports down to the beginning of 1889. In 1837 a bookseller named Stockdale brought an action for libel against the Messrs Hansard, the libel consisting of statements in the parliamentary reports which the latter had printed, and after more than one trial the judges decided in favour of Stockdale. To obviate any similar case an act of parliament was passed, directing that proceedings against persons for publication of papers printed by order of either House of Parliament are to be stayed by the courts of law, upon delivery of a certificate and affidavit that such publication is by order of either House. Cobbett's *Parliamentary History of England from 1066 to 1803* was continued from 1806 by the son and successors of Luke Hansard; and the name Hansard has been since then given to the printed reports of the debates in parliament. But the speeches there printed are not taken down by a special staff of shorthand writers; they are extracted in the gross from the London morning newspapers. They are usually sent to the peers or members by whom they were spoken for revision and correction. See *Biographical Memoir of Luke Hansard* (1829) and Report of Select Committee of House of Commons (1828).

Hanseatic League, or HANSA, a politico-commercial association or league of cities in the north of Germany and the adjoining states, which flourished all through the middle ages. Neither the circumstances out of which it grew, nor the date of its origin, can be precisely determined. The original germs of the union may undoubtedly be recognised in those fortuitous or temporary combinations of merchants, trading along the same routes or in the same places, which were formed for purposes of mutual protection, whether from pirates at sea or from robbers on land, at any-rate from the thousand and one vexations and dangers to which the isolated trader was in those rude times constantly exposed. In course of time more permanent associations were founded abroad, partly for mutual protection, partly for the purpose of securing from the rulers of the state they were domiciled in more favourable conditions for trade, partly in order to control the market and exclude from participation in it all who were not members of their own body.

The earliest guild of German merchants established in a foreign country seems to have been founded in London in or before the 12th century. Certain it is that traders from Cologne were at that time settled there in the enjoyment of special trading privileges. This guild was viewed with favour by the English kings, who from time to time conferred upon its members valuable prerogatives and advantages, in return for services which the wealth and connections of the guild allowed it to render to them. Thus it was with money borrowed from them that Edward III. carried on his campaigns in France. This royally-fostered colony of Easterlings (whence 'sterling,' from the purity of their coined money), as they were called by the English, subsequently, about 1474, developed into the powerful association known as the Merchants of the Steelyard. Other guilds existed later at Boston, Hull, York, &c. Another important centre of the Hanseatic cities in the early years of their confederation was Wisby, on the island of Bornholm in the Baltic. Here, although the guild embraced merchants from several towns, the influence of Lübeck reigned supreme, as that of Cologne did in London. This station was the chief depôt for the trade with Russia, and with the German colony of Livonia, the name given at that period to all the eastern seaboard of the Baltic as far north as the Gulf of Finland. Wisby was also the mother-city of a no less important Hanseatic settlement at Novgorod, near Lake Ilmen, in Russia. At Witten, in the province of Skåne, the southern portion of Sweden, which during the greater part of the middle ages belonged to Denmark; at Bergen, on the west coast of Norway; and at Bruges in Flanders there were Hanseatic depôts of first-rate importance, besides numerous others of secondary consequence scattered along the shores of the North and Baltic seas. Most of these trading-colonies were governed by their own

code of laws and customs, different from those of the country in which they were established. In fact each of them was to all intents and purposes an independent state within a state. As a general rule the members of the colony were not allowed to marry, were put through rough and trying initiation ceremonies, had to work their way up through the various grades of the guild, and after serving a certain number of years had to give place to newcomers from the mother-cities at home; whilst the regulations governing their domestic life, their style of housing, eating and drinking, and amusing themselves, were very similar to those which prevailed in the monasteries of the time.

But there was another and more important phase of the movement—viz. that which developed itself at home. At first the individual cities seem to have acted almost independently of each other in founding trading-colonies abroad; at all events the influence of Cologne was for some time supreme in London, and that of Lübeck supreme in Wisby. But gradually merchants from other commercial towns of Germany were admitted to share the prerogatives of the guild and colony. This spirit of association reacted in turn upon the mother-cities, and about the middle of the 13th century, under the cementing force of a close community of interests, the large trading-cities of north Germany began to co-operate together in leagues, more or less officially constituted. Amongst the earliest of supreme moment was that formed, at the period indicated, between Hamburg and Lübeck (1241) for the protection of the highways connecting the two cities. When, however, Lübeck, which had rapidly acquired a leading position among the commercial towns of north Germany, desired to enter the league of towns which had allied themselves with Cologne, the latter city strove hard to exclude her, but in vain. From this time dates the introduction of a political element into the league. Lübeck soon formed alliances with the Wendish towns on the Baltic, lying to the east—viz. Wismar, Rostock, Stralsund, and Greifswald. The Saxon and Westphalian towns, which had already banded themselves together in separate and independent confederations, joined the principal league, at the head of which Lübeck soon placed herself by common consent of the rest; and the Prussian towns associated themselves about 1340 with those of Westphalia. The cities of the principal league did not, however, form a democratic confederation of municipal states with a regular, well-conceived constitution, such as we find in confederated states at the present day. The first and principal object of the association was to maintain a monopoly of trade, by jealously excluding all rivals, in such countries as Russia, Norway, and the south of Sweden, as well as to preserve in their own hands the special commercial prerogatives which they had managed to acquire in countries like England and Flanders. Thus, in the beginning their interests were mainly concentrated upon their colonies and trading-depôts, and whatever foreign policy they may have had was shaped by the necessities of protecting or furthering those interests, which were of course of a purely commercial character. Yet, as their wealth increased, and therewith their political influence, these Phœnicians of the north began to pursue other than mere ordinary mercantile aims. In Norway, for instance, they insisted that the entire trade of the country, at least of the northern and western portions, should pass through their depôt at Bergen, where they ousted the native Norwegians from their own wharves and warehouses, seized upon their trade, and refused all obedience to the civic authorities of the town. And in Russia their behaviour was not a whit less arbitrary and high-handed. But the first awakening of the league to the consciousness that it was the possessor of real political power came in 1370, when it brought King Waldemar of Denmark, the most powerful and energetic sovereign on the Baltic shores, to his knees, and imposed upon him a humiliating peace. For many, many years relations between the Hanseatic merchants and the Danes had been, and continued to be, those of latent or open hostility, for the Danes were the only serious rivals the Hansa had to encounter, and Denmark had, as now, control of the Sound and the Belts, besides holding possession of the south of Sweden, off whose coasts the great herring fisheries, one of the principal sources of wealth to the Hanse merchants, were in those ages carried on.

From the peace of Stralsund (1370) the Hanseatic League claimed the right of controlling the election of each successive sovereign who was crowned king of Denmark. And by the 16th century its officers had advanced so far in statecraft, and the league itself had acquired so much political influence, that it was able to depose the king of Denmark (Christian II.), and bestow, not only his crown, but also that of Sweden, upon candidates of its own nomination. Yet its power was then already a century on the wane. This result was brought about by the co-operation of a variety of causes, chief amongst which were the following. The discovery of America and of the sea-route to India struck the severest blow at the Hansa by diverting the stream of commerce from the Baltic to the Atlantic shores of Europe. Amongst other changes, it caused a falling-off in the demand for furs, a staple commodity of Novgorod; while towards the middle of the 15th century the herrings ceased to enter the Baltic in such large quantities, but began to direct their course instead to the coasts of Holland. The Dutch members of the league broke away from it early in the 15th century, and by adapting themselves to the altered conditions of the age, soon rose to be formidable rivals of their former associates. The English too were laying the foundations of their subsequent commercial supremacy, and in 1598 Elizabeth deprived the Steelyard merchants of all their privileges, and banished them from the country. The discovery by Sir Richard Chancellor of the sea-route to the White Sea struck a fatal blow at the monopoly hitherto enjoyed by the Hanse merchants in the trade with Russia. The conversion of so many European nations to Protestantism greatly lessened the demand for dried and salted herrings in Lent, as well as for wax for candles, which the Hanse merchants imported in large quantities from Novgorod. In the middle of the 16th century the 'contor' or depôt of Bruges was removed to Antwerp, where, however, the old-fashioned methods of doing business still practised by the Hanse merchants were unable to compete successfully against the more modern and enterprising methods of the Dutch and the Flemings. And unity no longer prevailed within the league itself, for, whilst Lübeck clung with jealous tenacity to the antiquated conservative policy of the past, Hamburg insisted upon conforming itself to the newer conditions of the age; and several of the other towns, finding that the advantages which had formerly accrued to them from their participation in the league were no longer reaped by them, fell off from it one after the other. But the decay must also be attributed in large measure to the advances made by the states of Europe in the knowledge and application of the principles of government; whilst the more perfect preservation of public order, and the removal of many of the vexatious impediments to the free circulation of commerce, deprived

the league of its most efficient *raison d'être*. Finally the Thirty Years War occasioned an entire derangement, and even at times cessation, of all trade relations, a state of things from the evils of which the members of the league never were able to recover. From 1628 onwards the only cities which made any real endeavours to revive the once powerful association were Lübeck, Hamburg, and Bremen. But the resuscitated league, even after its confirmation by the treaty of Vienna in 1815, was more a thing of name than of reality; and in the 19th century Hanseatic cities was not so much the collective title of a combination of towns for trading purposes, as a common name for the independent republican municipal states of Hamburg, Bremen, and Lübeck. In 1870 each of these was made an integral part of the German empire, and by 1889 all had joined the German imperial customs union.

The administration of the affairs of the league was in the hands of deputies representing the constituent towns of the confederation, who met together at least once in every three years, though as a general rule every year, at one of the towns of the league, usually at Lübeck, at which town the archives of the Hansa were always preserved. These assemblies represented the political corporation of the Hanseatic cities; they determined the amount of the duties to be levied on imported and exported goods, fixed the amount of the periodical contributions to be paid by the several towns to the common treasury of the league, decided all questions of peace and war, settled all internal quarrels between the members of the league, and punished disobedient or offending towns by fine, or, in the last instance, by exclusion from the Hansa, called 'unhansing.' As it was always the practice for towns to join the confederation and withdraw from it at their own will, it is not possible to state the precise number of towns which constituted the league. The war against Waldemar of Denmark, which took place when the Hansa was at the summit of its power, was waged by at least seventy-seven cities, though probably the league embraced more than these. See histories of the league by Sartorius (1802–8), Lappenberg (1851), Barthold (1862), and Helen Zimmern (in English, 1889); also the *Hanse Recesse*, or official proceedings of the assemblies (1873 *et seq.*).

Hansi, a town of the district of Hissar, in the province of the Punjab, about 80 miles NW. of Delhi, was a British cantonment from 1802 down to the Mutiny (1857). Pop. 12,656.

Hansom. See CABS.

Hansteen, CHRISTOPH, a Norwegian astronomer, was born at Christiania, 26th September 1784. In 1814 he was appointed to the chair of Mathematics in the university of Christiania, and there, in 1819, published his famous work, *Investigations into Terrestrial Magnetism*, the methods of observation described in which have been generally followed since, and which he himself applied in the course of a journey to the east of Siberia in 1828–30. The scientific results of this journey were published in 1863. In 1821 he discovered the 'law of magnetic force': see MAGNETISM. It was chiefly by his initiative that the astronomical and magnetic observatories at Christiania were founded. He was also professor of Mathematics in the School of Artillery, superintendent of the triangulation of Norway, and reorganiser of the national system of weights and measures. He died at Christiania, 11th April 1873. He published lectures on astronomy, a work on mechanics, another on geometry, several on terrestrial magnetism, and numerous memoirs, of which the greater part are inserted in the *Magazin for Naturvidenskaberne*.

Hanumân is the name of a fabulous monkey, who plays a great role in the legendary history of the second or classical period of Hindu mythology. He is represented there as the strenuous friend and ally of Vishnu, when the latter, in his incarnation as Râma, made his expedition to Ceylon, in order to recover his wife Sîtâ, carried off by the giant Râvana. In the war between Rama and Ravana, Hanumân, on one occasion, is related to have bridged over the ocean between the continent of India and Ceylon with rocks of a prodigious size, which he and his friends threw into the sea. See ENTELLUS MONKEY, VISHNU.

Hanway, JONAS, an eccentric English traveller and philanthropist, born at Portsmouth in 1712. Apprenticed at seventeen to a Lisbon merchant, he afterwards traded at St Petersburg, and in the September of 1743 left that city on an adventurous journey through Russia and Persia, returning in the July of 1750. He published an account of his travels in 1753, and spent the rest of his life mostly in London as one of the commissioners for victualling the navy from 1762 to 1783. He was an unwearying friend to chimney-sweeps, parish infants, and unfortunates, and advocated with earnestness solitary confinement for prisoners, and a milder system of punishment generally. Further, he deserves grateful remembrance for having written down the giving of vails, and as the first Englishman to carry an umbrella at home in spite of the interested insolence of the hackney-coachmen. His attack on tea-drinking was less successful, but here he had the honour to be opposed by Dr Johnson, who for once replied to an attack by answering Hanway's angry answer to his review of his *Essay on Tea*. Elsewhere Johnson said that 'Jonas acquired some reputation by travelling abroad, but lost it all by travelling at home.' He died September 5, 1786. See Pugh's *Remarkable Occurrences in the Life of Jonas Hanway* (1787).

Hanwell Asylum, the lunatic asylum for the county of Middlesex, is situated, not in the parish of Hanwell, but in the adjoining parish of Norwood, 7½ miles W. of Paddington Station, London. It was originally founded in 1831, and now gives shelter to about 1800 patients.

Han-yang. See HANKOW.

Haparanda, a town in the Swedish province of Norrbotten, 1½ mile from the mouth of the river Torneå, and opposite the Finnish town of Torneå (q.v.). It is the commercial outlet for the northernmost province of Sweden, and possesses a meteorological station. Pop. 1150.

Haplodon (lit. 'simple toothed'), a terrestrial rodent peculiar enough to be formed into a family by itself, and regarded as a connecting-link between beavers and squirrels. It is represented by a single species (*H. rufus*), restricted to 'a small area on the west coast of North America, in Washington and Oregon territories, and a portion of California.' The aborigines called it 'Showt'l' or 'Sewellel,' the trappers the 'Boomer' or 'Mountain Beaver.' The animal is plump, with broad head, short limbs, and hardly any tail; measures about a foot in length; and has a brownish colour. It lives socially in colonies, burrows underground, and lives on vegetable matter. As a connecting-link Haplodon is of much interest to naturalists, while the Indians use its skin and probably also its flesh.

Hapsburg, or HABSBURG, HOUSE OF, of which the imperial family of Austria are the representatives, derived its name from the castle of Habsburg, or Habichtsburg (Hawk's Castle), on the Aar, in the Swiss canton of Aargau. The castle was built by Werner, Bishop of Strasburg

(1001–29). The real founder of the family was, however, Albert, who is mentioned in the annals as Count of Hapsburg in 1153. He was appointed landgrave of Upper Alsace, lord of the Zurich hundred, and suzerain of various abbeys by the Emperor Frederick I. Under him and his son, Rudolf I., the family became one of the most powerful in Swabia, including under their rule the territories of the bishops of Constance, Strasburg, Basel, Coire, Lausanne, and those of the abbot of St Gall, with some temporal fiefs. After Rudolf's death in 1232, his sons, Albert IV. and Rudolf II., divided their father's possessions – Rudolf becoming the founder of the Hapsburg-Lauffenburg line. This line again divided into two branches, which became extinct in 1408 and 1415 respectively. Albert IV. laid the foundation of the future greatness of the House of Hapsburg. His eldest son, Rudolf III. (Rudolf I. of Austria), who succeeded him, and who was subsequently (1273) elected emperor, by appropriating the provinces which he had wrested from Ottocar of Bohemia—viz. Upper and Lower Austria, Styria, and Carniola—greatly increased the power of his family. To the family's territories were added in 1336 Carinthia, and in 1364 the Tyrol. On the death of Rudolf IV. (1365) the house divided into the Austrian and Styrian branches; but the former became extinct in 1457, whilst the latter have worn the imperial crown almost uninterruptedly down to the present time (see AUSTRIA, GERMANY, and SPAIN). Meanwhile the original family possessions were gradually absorbed by the Swiss confederated cantons (1386–1474). In 1881 the Austrians proposed to purchase the castle of Hapsburg and give it as a wedding gift to the Crown-prince of Austria; but the people of Aargau refused to hear of the sale.—Compare Prince Lichnowski, *Geschichte des Hauses Habsburg* (1837); also Coxe's *House of Austria* (1807).

Harar, a city of Africa, in the country of the Gallas, about 200 miles WSW. of Berbera, stands on the slopes of the mountains which surround it, Mount Hakim on the west rising to 8400 feet. It is fenced with a low wall and forts, the wall being pierced by five gates. The streets are simply water-channels crossing the uneven surface; the houses are partly stone edifices, partly huts. In the neighbourhood are fine banana groves and coffee gardens. Formerly the place was a commercial centre of considerable importance, but it has now lost a good deal of its trade to Tadjura and Berbera. Coffee, hides, cattle, and a dyestuff called *wars*, are the principal objects of commerce. The population number about 37,000, of whom two-thirds are females. They include native Harari (nearly one-half), Gallas, Somali, and Abyssinians. The Harari, though physically resembling the Abyssinians, differ both in their dress and manners from all their neighbours, but are rapidly becoming assimilated in these respects to the Arabs. Their language would seem to belong to the Hamitic division, and is probably a descendant of the ancient Ge'ez, though Arabic is replacing it for commercial purposes. Harar, which was converted to Islam in 1521, was formerly the capital of an independent state. In 1875 it was conquered by the Egyptians, who gave it back to its native emir; Italian in 1890–97, it is now British. See Burton's *First Footsteps in East Africa* (new ed. 1894).

Harbour, an inlet of the sea, so protected from the winds and waves, whether by natural conformation of the land, or by artificial means, as to form a secure roadstead for ships. It is with harbours which are wholly or in part artificial that this article deals.

Harbours may be divided into harbours of refuge and those for commercial purposes. The latter are often merely tidal—i.e. capable of being entered by vessels only at certain states of the tide, and where the vessels rise and fall with the tide. The former are roadsteads of good depth, protected by breakwaters, and accessible at all times of tide, where ships may take refuge during storms. The two kinds are sometimes combined, there being the harbour proper, and a capacious protected roadstead outside of it, as at Cherbourg and elsewhere.

With the birth of commerce and naval warfare, in the earliest ages of civilisation, arose the necessity for artificial harbours. The Phœnicians, the fathers of navigation, soon set to work to protect their scanty strip of Levantine coast. At Tyre two harbours were formed, to the north and to the south of the peninsula on which the city was placed. At Sidon similar but less extensive works long testified to the wealth and engineering genius of the Phœnicians. The breakwaters were principally constructed of loose rubble.

Carthage, in another part of the Mediterranean, also possessed a harbour, in two divisions, formed by moles, and connected with one another by a canal 70 feet wide. On the inner harbour stood the arsenals, with room around them for 220 warships. Still keeping to the great inland sea, we come to Greece; but here nature had provided so many navigable inlets that little remained to be done by man. Nevertheless, some minor works were executed at the Piræus and elsewhere, chiefly, of course, for warlike purposes. The Romans, finding ships necessary to the dominion of the world, set about constructing harbours for them, in their usual solid and workmanlike manner. The coasts of Italy still show how well they understood both the principles and the practice of this branch of marine engineering. Below is given a plan of the ancient port of Ostia, at the mouth of the Tiber (now more than two miles inland), one of their finest and most complete undertakings of this nature. A distinguishing feature

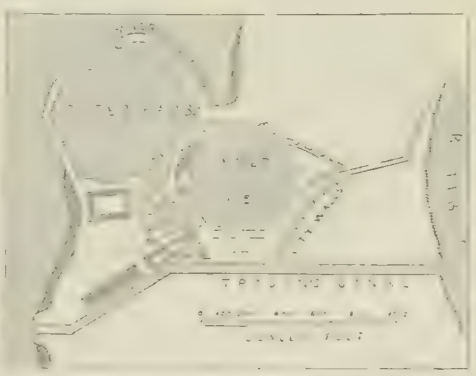


Fig. 1.—Ancient Harbour of Ostia.

of their harbour-making is the open or arched mole. Built with open arches, resting upon stone piers, it gives full play to the tidal and littoral currents, thus preventing the deposit of sand or mud; but in proportion as this advantage is increased (by increasing the span of the arches), so also is the agitation, and consequent insecurity, of the water within. The decay of commerce and civilisation, consequent upon the fall of the Roman empire, put a stop to harbour-making; nor could any want of the art be felt until the revival of commerce by the Italian republics of the middle ages. But the rich traffic of Venice and Genoa soon led to the construction of suitable ports at those places; and

the moles of the latter city and the works in the lagoons of Venice remain to this day. France was next in the field, embanking, protecting, and deepening the mouths of the rivers along her north-western shores, as at Havre, Dieppe, Dunkirk, &c. In 1627, during the siege of Rochelle, Metezeau constructed jetties of loose rubble-stone, to prevent access to the city.

Meanwhile, Britain, whose ocean commerce is of comparatively recent date, lagged far behind her continental rivals. With few exceptions her ports were absolutely unprotected, or rather uncreated; and this state of things continued until late in the 18th century. Two of the few exceptions were Hartlepool, where a harbour was formed about 1250, and Arbroath in 1394. In the 17th century, at Whitby and Scarborough rough piers were thrown out, protecting the mouth of the port; while at Yarmouth a north jetty and subsequently a south one were formed. An ancient mole existed at Lyme Regis, a section of which, from Smiles's *Lives of the Engineers*, is given below (see fig. 3). But the chief efforts of the early English engineers were directed against the shoals and waves of

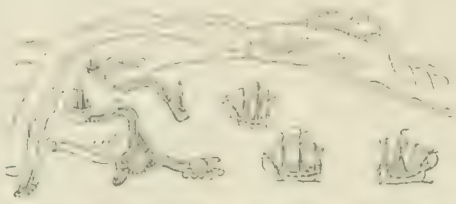

Fig. 2.—Dover Harbour in the time of Henry VIII.

Dover. When, however, Smeaton rose to vindicate the engineering talent of England, things took a different turn; and now few countries surpass Great Britain in the number of artificially improved

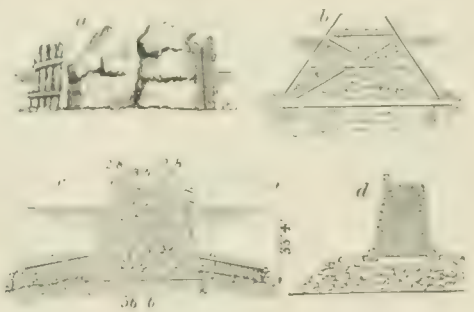

Fig. 3.

a, ancient pier at Lyme Regis; b, wooden framed pier, filled with stones; c, pier at Havre, with apron; d, Hartlepool pier, constructed of masonry.

commercial harbours, or in the just appreciation of their importance.

In the construction of harbours the great desiderata are sufficient depth of water and perfect security for the vessels likely to frequent them, together with the greatest possible facilities for ingress during any weather; while the chief obstacles to be surmounted are the action of the waves upon the protecting piers and breakwaters, and the formation of sandbanks and bars, which diminish the depth of water at the entrance and also within. The designs of harbours, as has been already indicated, may be classified under the following heads: (1) harbours of refuge and anchorage breakwaters; (2) deep-water and tidal harbours for commercial purposes; (3) piers, either straight, or kanted, or curved; (4) quays or wharves.

These different works are obviously suited for different localities, and for contending with different exposures. Quays are clearly suited for the most sheltered situations only, and the engineer must consider, when designing a harbour, which type of harbour will be most economical and effective. In coming to a decision the nature of the traffic, the exposure, and the geological features of the coast must be carefully considered. A good chart or marine survey furnishes valuable evidence as to the force to which harbour-works will be exposed. Among the points to be noted is the *line of maximum exposure*, or the greatest fetch or reach of open sea, as well as the depth of water, in front of the harbour. Thomas Stevenson proved by observations that *the waves increase in the ratio of the square root of their distance from the windward shore* as measured along the line of exposure, and he gives the following simple formula: Where h = height of wave in feet during a strong gale, and d = length of exposure in miles for distances of, say, 10 miles and upwards, then $h = 1.5\sqrt{d}$. The heights so obtained will be increased when they pass into converging channels, and decreased when they pass into expanding channels. The greatest measured height of the waves was by Scoresby in the Atlantic Ocean, where he found billows of 43 feet in height from hollow to crest, and 36 feet was not an uncommon height. At Wick, Caithness-shire, waves of about 40 feet have struck the breakwater. Amongst the greatest recorded forces exerted by the waves may be mentioned the breaking or quarrying out of its position *in situ* of a mass of 13 tons on the Skerries of Whalsay, in Shetland, at a level of 74 feet above the sea—this height, of course, being reached by *sliding*. But the most astonishing feat of which we have any knowledge was at Wick breakwater, where in the winter of 1872 a mass of masonry, concreted together as a monolith, and bound with iron bars 4½ inches in diameter, and weighing no less than 1350 tons, was torn from its seat in the work, and thrown to leeward.

Thomas Stevenson devised an instrument called the Marine Dynamometer for ascertaining *numerically* the force which is exerted by the waves in the Atlantic and German oceans. He found that the mean of his observations during winter was more than three times that exerted during summer, the maximum force recorded being 3½ *tons per square foot*.

Various local causes materially affect the height, and therefore the force of the waves. In some cases, where a strong current runs past the coast, as at Sumburgh *roost* in Shetland, it causes a dangerous breaking sea in the current, and while this *roost* or race continues to rage the coast under lee is comparatively sheltered; but when the force of the tide is exhausted and the *roost* disappears, a heavy sea rolls in upon the shore. It is this encounter between the ground-swell waves of the ocean and the current of tide or land water which causes miniature races at the mouths of rivers.

Another most material element in the question of exposure is the depth of water in front of the harbour; for, if that depth be insufficient to admit of the transmission of the waves, they break or spend themselves before they reach the piers. Thus, Leslie found at Arbroath harbour that the works were not so severely tried by the heaviest waves as by others of lesser size which were not tripped up and broken by the outlying rocks. In the same way, at the river Alne the harbour within the bar is more disturbed by ordinary waves than during great storms. It thus appears that the

largest waves are not always so destructive as smaller ones. Scott Russell has stated the law that waves break whenever they come to water as deep as their own height; so that 10-feet waves should break in 10-feet water, and 20-feet waves in 20-feet water. There seem, however, to be some waves which break on reaching water whose depth is equal to twice their own height. Proofs of the depth to which the surface undulations extend have been given by Sir George Airy, Sir John Coode, Captain Calver, and Mr John Murray, C.E. Rankine has shown that the crest and trough of the sea are not, as was generally believed, equidistant from the level of still water. When l is the length of the wave, H its height from trough to crest,

$$\text{Crest above still water} = \frac{H}{2} + \cdot 7854\frac{H^2}{l}.$$

$$\text{Trough below still water} = \frac{H}{2} - \cdot 7854\frac{H^2}{l}.$$

It has been held by some engineers that in deep water waves are purely oscillatory, having no power of translation, and therefore incapable of exerting any force against a vertical face of masonry. This, however, is incorrect. Were there no wind propelling the waves, no current to interfere with their character, and no interference with one another, such as the reflected wave from a vertical face meeting the next opposing wave, such a theory might be true. True, however, it is not; and all sea-works, in whatever depth of water they may be placed, will assuredly have to withstand impulsive action. Besides, it must be kept in view that in order to reduce the expense of construction it is essential, where the bottom is soft, to make the foundation a pile of loose rubble or concrete blocks. It follows from what has already been said that the rubble, by shoaling the water in front of the work, will cause the waves to become waves of translation before they reach the vertical superstructure, which, assuming the waves to have been simply oscillatory, would have reflected them without breaking, and therefore without their having exerted an impulsive force further than statical pressure upon the masonry.

There is no fixed rule as to the best profile of any sea-work, which must necessarily depend upon a variety of local peculiarities, such as the nature of the bottom, and the size and quality of the materials obtainable. While a long, sloping breakwater does not offer the same amount of resistance to the waves, neither is it in itself so strong, for the weight resting on the face-stones is decreased in proportion to the sine of the angle of the slope. On the other hand, the tendency of the waves to produce horizontal displacement, supposing the direction of the impinging particles to be horizontal, is proportional *to the cube of the sine of the angle of elevation of the wall.*

In tidal harbours, or those in shoal-water, it is admitted by all that the waves break, and therefore exert an impulsive force. Such works have to withstand (1) the direct horizontal force which tends to remove the masonry; (2) the vertical force acting upwards on projecting stones or protuberances, and against the lying beds of the stones; (3) the vertical force acting downwards upon the talus wall, or passing over the parapet and falling upon the roadway; (4) the back-draught, which is apt to remove the soft bottom in front of the work; and (5) the blowing action of waves on the air or water which fills the interstices of open-work piers.

In designing the ground-plan of harbours, some rules should be kept in view: (1) the entrance should be always kept seawards of the works of masonry, care being taken that the direction of the piers does not throw the sea across the entrance; (2) there should be a good 'loose,' or point of departure free of rocks or a lee-shore; (3) spending beaches inside should be provided to allow the waves that pass in to break and spend themselves. A harbour basin surrounded with vertical quay walls becomes a 'boiling pot;' this is a point frequently overlooked by engineers; (4)

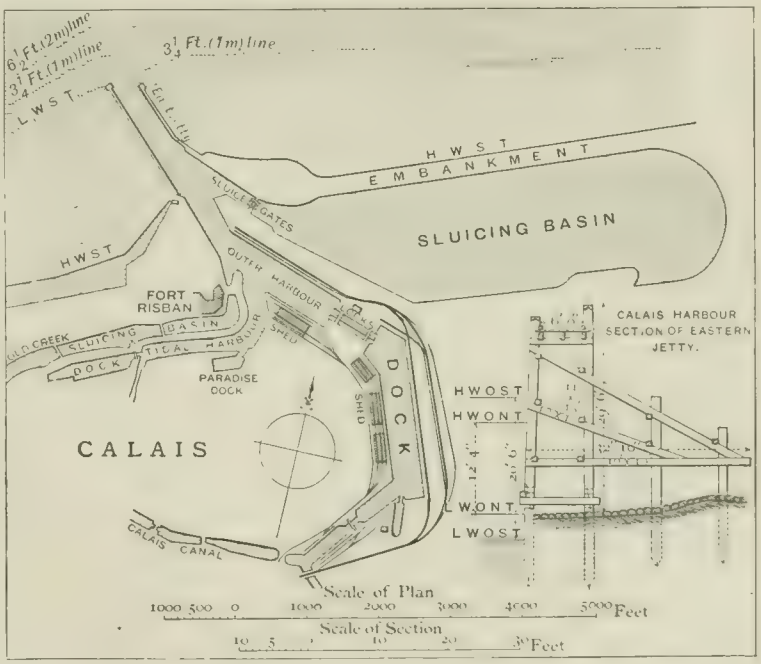

Fig. 4.—Calais Harbour.

the relation of the width of entrance to the area of a harbour should be a matter of careful study, as upon this depends the tranquillity of the interior, or what has been called the reductive power of the harbour. Stevenson's formula for the reductive power is given below: H = height of wave at entrance; b = breadth of entrance; B = breadth of harbour at place of observation; D = distance from mouth of harbour to place of observation; x = reduced height of wave at place of observation.

$$x = \frac{H \sqrt{\frac{b}{B}}}{\left(H + H \sqrt{\frac{b}{B}}\right) \sqrt{D}}.$$

Fig. 4 represents the harbour of Calais, which was constructed by the French government, and opened on 3d June 1889. Great difficulty was

experienced in keeping the entrance free from sand, the old sheeting basin being found quite inadequate for the purpose on account of its distance from the entrance. The large basin constructed has proved more effective, enabling much larger steamers now to be put upon the passage.

Rendel's plan of depositing rubble from open stages of pile-work is frequently used in the construction of deep water piers.

The cross-sectional form of breakwaters depends naturally on the depth of water, exposure, and the materials that can be most easily obtained. The system of bringing up a rubble mound to within 12 or 18 feet of low-water level, and then forming a masonry wall on this base, was adopted at Portland, Alderney, Wick, Holyhead, and other places; while at Dover and Aberdeen the wall with a slight batter has been brought up from the bottom. The introduction of Portland cement concrete in comparatively recent times, as described in the article BREAKWATER Vol. II. p. 415, has greatly facilitated the work of the harbour engineer.

The commercial value of a harbour increases, according to Stevenson, not simply as the depth of the water is increased, but as *the cube of the depth*. Hence the great expense which is willingly incurred for securing even a foot or two of additional depth. The greatest achievement in deepening is at the Tyne, where Ure dredged out the channel to 20 feet at low-water all the way up to Newcastle. In 1889-95 Messrs Stevenson of Edinburgh deepened the lower reaches of the Clyde to 22 feet at low water spring tides. Scouring is also employed for increasing the depth, as by Sir W. Cubitt at Cardiff, where 2500 tons of water a minute are let off. Rendel's scheme for Birkenhead was based simply on the quantity liberated and the sectional area of the channel, and was therefore operative for any distance, and did not depend on the propelling head, or on the direction in which the water left the sluices, which conditions regulate ordinary scouring on the small scale, and which is efficacious for only short distances from the outlet.—Docks (q.v.) of various kinds are connected with harbours.

Pine timber is admirably adapted for soft soils, when the exposure is not great, but, owing to the ravages of the *Teredo navalis* and *Limnoria terebrans* in localities where there is no admixture of fresh water, it is soon destroyed. Greenheart, African oak, and bullet-tree are little affected by the worm, as shown by experiments made in 1814 at the Bell Rock by Robert Stevenson. Even limestone and sandstone are perforated by the Pholades and Saxicavæ. Metals also suffer from chemical action when immersed in salt water. George Rennie's experiments showed that wrought iron resists this action better than cast in the ratio of 8 to 1; while Mallet's experiments show that from $\frac{1}{10}$th to $\frac{4}{10}$ths of an inch in depth of castings 1 inch thick, and about $\frac{6}{10}$ths of wrought iron, will be destroyed in a century in clean salt water. A cannon-ball 4½ inches in diameter became oxidised to the extent of $\frac{3}{4}$ths of an inch in the century.

See BREAKWATER, DOCKS, COALING STATIONS, and the articles on CALAIS, CHERBOURG, DOVER, HAVRE, HOLYHEAD, PLYMOUTH, PORTLAND, &c.; also Sir John Rennie's book on *Harbours*, 4 vols. 1851-54; Thomas Stevenson, *Design and Construction of Harbours*, 3d ed. 1886; L. F. Vernon Harcourt, *Harbours and Docks*, 2 vols. 1885; and the Minutes of Institution of Civil Engineers, *passim*.

Harbour Grace, a port of entry and the second town of Newfoundland, on the west side of Conception Bay, 84 miles by rail WNW. of St John's, has a large but somewhat exposed harbour, with a revolving light, and carries on a considerable trade. It is the seat of a Roman Catholic bishop, and contains a Catholic cathedral and convent. Pop. 7054.

Harburg, a seaport of Prussia, in the province of Lüneburg, is situated 5 miles S. of Hamburg, on the Elbe. Its industries include gutta-percha goods, palm-oil, cotton-seed oil, saltpetre and other chemicals, artificial manure, walking-sticks, leather, mineral water, machines, beer, and jute. Since the deepening of the Elbe the commerce of Harburg has greatly increased. It is a place of holiday resort for the Hamburgers. Pop. (1875) 17,131; (1885) 22,344.

Harcourt, SIR WILLIAM VERNON, the second son of the late Rev. William Vernon Harcourt of Nuneham Park, Oxfordshire, and grandson of a former Archbishop of York, was born October 14, 1827, and educated at Trinity College, Cambridge, where he graduated with high honours in 1851. He was called to the bar in 1854, went the Home Circuit, and was made a Queen's Counsel in 1866. It was during this period that he acquired distinction by his contributions to the *Saturday Review*, and his letters in the *Times* under the signature of 'Historicus.' After unsuccessfully contesting the Kirkcaldy burghs, he was returned to parliament for the city of Oxford as a Liberal in 1868. The following year he was elected professor of International Law in the university of Cambridge. He took an independent tone in the House of Commons, sometimes attacking both friends and foes. But the undoubted mark which he made by his abilities and oratory caused him to be appointed solicitor-general in November 1873, when he received the honour of knighthood. He held office until Mr Gladstone's retirement in February 1874, and when that statesman returned to power in 1880 he was appointed Home Secretary. On seeking re-election at Oxford, however, he was defeated, but was almost immediately returned for Derby upon the opportune retirement of Mr Plimsoll. During the session of 1880 Sir William piloted the Ground Game Bill through the House of Commons, and in 1881 he introduced the Arms Bill (Ireland) in a speech which was strongly resented by the Irish members. He brought in the Prevention of Crimes Bill (1882) and the Explosives Bill of 1883, which dealt summarily with dynamite outrages. He next made an abortive attempt to grapple with the municipality of London. The ministerial policy in the Soudan he defended with much skill on various occasions. In 1885 Sir William went out of office with his chief, but returned with him, as Chancellor of the Exchequer, to power for six months in 1886—an office he resumed in Mr Gladstone's Home Rule cabinet of 1892, and held till 1895. He was elected leader of the Liberal party (out of office) on the resignation of Lord Rosebery in 1896, which office he resigned in December 1898. The letters of 'Historicus' were published in volume form in 1863.

Hardanger Fjord. See NORWAY, p. 529.

Hardenberg. HEINRICH VON. See NOVALIS.

Hardenberg, KARL AUGUST, PRINCE VON, a Prussian statesman, was born at Essenroda, in Hanover, May 31, 1750. After labouring for twelve years (1770-82) in the service of Hanover and eight in the service of Brunswick, Hardenberg chanced to attract the attention of Frederick-William II. of Prussia. On his recommendation he was nominated administrator of the principality of Ansbach and Baireuth, and after the union of this latter to Prussia in 1791 was appointed a Prussian minister of state and a member of the cabinet ministry. In this capacity his chief work was the negotiation of peace between Prussia and the French Republic at Basel in 1795. On the accession of Frederick-William III. in 1797,

Hardenberg was entrusted with the management of important branches of internal affairs, and in 1803 became first Prussian minister. The principal aim of his policy was to preserve neutrality in the war between France and England; but in 1806, when Prussia was coerced by Napoleon into becoming his ally, Hardenberg was dismissed. In 1810, however, he was appointed chancellor of state in succession to Stein (q.v.); and although Prussia was at this period in a deplorable condition, humbled in the very dust before France, Hardenberg addressed himself to the task of completing the internal reforms begun by his predecessor. In the war of liberation he took a prominent part, and saw his efforts crowned by the treaty of Paris, June 1814. Soon after he was raised to the rank of prince. He accompanied the allied sovereigns to London, took part in the proceedings of the congress at Vienna, and in the treaties of Paris (1815). In 1817 he reorganised the council of state, of which he was appointed president. He was also present at the congresses of Aix-la-Chapelle, Carlsbad, Vienna, Laubach, and Verona; and drew up the new Prussian system of imposts. During a tour through the north of Italy he was taken ill at Pavia, and died at Genoa, 26th November 1822. To Hardenberg Prussia is mainly indebted for the improvements in her army system, the abolition of serfdom, of the privileges of the nobles, and of a multitude of trade corporations, the encouragement of municipal institutions, and the reform of her educational system. Yet in his later years he was unable to overcome the reactionary tendencies of the king; all he could do was to moderate them and prevent them running to excess. See Ranke's *Denkwürdigkeiten des Fürsten von Hardenberg* (5 vols. 1877), which includes Hardenberg's own memoirs.

Harderwijk, a fishing-town of the Netherlands, on the south-east shore of the Zuider Zee, 31 miles NE. of Utrecht by rail. From 1648 to 1811 it was the seat of a university. It is now a depôt for recruits for the Dutch East Indian army. Pop. 7339.

Hardhead. See MENHADEN.

Hardicanute, king of England, son of Canute the Great by Emma of Normandy, the widow of Ethelred II. At the time of his father's death (1035) Hardicanute was in Denmark, and the throne of England was given by the witenagemot to Harold, his younger brother; Wessex, however, was reserved for the absent prince, whose claims to the kingdom were upheld by Godwin and Emma. On the death of Harold in 1040 Hardicanute was elected king in his place; but he only reigned two years, dying of apoplexy in 1042. Yet in that short time he provoked the discontent of his subjects by the imposition of a very heavy *danegeld*.

Harding, STEPHEN, the third abbot of the celebrated monastery of Cîteaux, an Englishman by birth, who endeavoured to restore the Benedictine rule to its original simplicity. He died in 1134. See CISTERCIANS.

Hardinge, HENRY HARDINGE, VISCOUNT, British general and governor-general of India, was born at Wrotham, in Kent, 30th March 1785. Gazetted an ensign in 1798, he served all through the Peninsular war, fighting in most of its battles, being wounded at Vimiera and Vittoria, and taking a decisive part in the sanguinary contest at Albuera. From 1809 to 1813 he was also attached to the Portuguese army as a deputy quartermaster-general. On the renewal of hostilities after Napoleon's escape from Elba, Hardinge hastened to join Wellington, who appointed him commissioner at the Prussian headquarters. In consequence of a severe wound received at Ligny he was unable to take part in the battle of Waterloo. From 1820 to 1844 he took an active share in parliamentary life, was Secretary for War under Wellington in 1828, and afterwards Chief Secretary for Ireland. In 1844 he was appointed Governor-General of India. It was during his tenure of office that the first Sikh war broke out. After the peace of Lahore (1845) he was created a viscount, and granted a pension of £5000 by the East India Company, as well as one of £3000 for three lives by parliament. In 1852 he succeeded Wellington as commander-in-chief of the British army. In 1855 he was made field-marshal. In July of the following year he resigned the office of commander-in-chief, and on the 24th of September 1856 died at South Park, near Tunbridge. See the monograph by his son (1891).

Hard Labour. See PRISONS.

Hardouin, JEAN, an eccentric classical scholar, was born in 1646, at Quimper, in Brittany, entered the Jesuit order at the age of twenty, and from 1683 filled the post of librarian of the college of Louis le Grand in Paris. In a spirit of eccentric scepticism, Hardouin maintained that the entire body of classical literature, with the exception of Cicero's writings, Pliny's *Natural History*, Virgil's *Georgics*, Horace's *Satires* and *Epistles*, Homer's *Iliad*, and Herodotus's *History*, was spurious, and had been written by the monks of the 13th century. He also rejected all the reputed remains of ancient art, together with the inscriptions and coins which are attributed to classical times; nay, he even extended his scepticism to the Septuagint version of the Old Testament, and to the Greek text of the New, the original language of which he held to have been Latin! Besides this, he condemned as apocryphal all councils of the Church anterior to the Council of Trent. Yet, with all this extravagance, Hardouin was a scholar of real attainments, and most of his works possess historical and critical value, particularly his edition of Pliny (5 vols. 4to, Paris, 1689). Of his remaining works, the most valuable is the *Collectio Conciliorum* (12 vols. folio, Paris, 1715); a commentary on the New Testament, in folio; and several volumes on numismatics and chronology. He died at Paris, September 3, 1729.

Hardwár (*Haridwára*, 'Vishnu's gate'), perhaps the most famous spot on the Ganges, stands on the right or west bank of the river, at the point where it emerges from the sub-Himalaya into the plains of Hindustan, 39 miles NE. of Saharunpur, North-west Provinces. From its position on the sacred stream, it attracts immense numbers of pilgrims for the purposes of ablution, as many as 100,000 in ordinary seasons (March and April), but every twelfth year a sacred festival brings about 300,000. Hardwár is 1024 feet above the sea, and has a pop. of 4520. See GANGES.

Hardy, ALEXANDRE, a prolific Parisian dramatist (1570?–1630?), from 1600 attached as playwright to the newly-started Théâtre du Marais, for which he wrote from five to seven hundred pieces, of which but forty-one are extant. Of his plays (ed. Stengel, 5 vols. Marburg, 1883–84) the best is *Mariamne*.

Hardy, SIR THOMAS DUFFUS, a distinguished palæographer, was born in 1804, in Jamaica, the son of a major of artillery. His earliest writings—illustrating the reign of King John—appeared in *Archæologia* and the *Excerpta Historica*. In 1861 he succeeded Sir Francis Palgrave as deputy-keeper of the Public Records, in which capacity his learning was equalled only by his courtesy. He was knighted in 1870, and died in London 15th June 1878. His most important works were two folio volumes of the early *Close Rolls* (1833–44), one of the *Patent Rolls* (1835), and others of the *Norman Rolls* (1835) and *Charter Rolls* (1837) for the Record Commission; *Catalogue* of Lord Chancellors,

Keepers of Great Seal, Masters of Rolls, &c. (1843); a *Descriptive Catalogue of MSS.* on British history, 3 vols. 1862–71; and *The Register of Richard de Kellawe*, 1873–78. His brother, SIR WILLIAM HARDY, was born 6th July 1807. On his brother's death in 1878 he succeeded as deputy keeper, was knighted in 1883, and died 17th March 1887. He edited Waurin's *Recueil des Chroniques* (4 vols. 1864–84).

Hardy, SIR THOMAS MASTERTON (1769–1839), born at Portisham, in Dorsetshire, was closely associated in his naval career with Nelson (q.v.).

Hardy, THOMAS, one of the foremost of modern English novelists, a writer of singular power and of marked individuality, was born at Upper Bockhampton, in Dorsetshire, on 2d June 1840. He was trained as an ecclesiastical architect at Dorchester, but spent a great part of his pupilage in reading Latin and Greek with a fellow-student. In London in 1863 he gained the prize and medal of the Institute of British Architects and Sir W. Tite's prize for architectural design; here too he found time to study, at King's College and otherwise, modern languages, literature, and theology. He also began to write: an article, 'How I built myself a House,' appeared in *Chambers's Journal* in 1865, and ranks as his first published production. The experiment of a not unsuccessful novel, *Desperate Remedies* (1871; new ed. 1896), shaped his destiny; and about 1873 he definitely forsook the profession of architecture for that of literature. *Under the Greenwood Tree* (1872), remains one of his most charming stories; and this and *A Pair of Blue Eyes* (1873) prepared the way for his first great work, *Far from the Madding Crowd* (1874), which, first issued in *Cornhill* as a serial, has remained on the whole his most popular book. It was followed by *The Hand of Ethelberta* (1876), *The Return of the Native* (1878), *The Trumpet-major* (1880), *A Laodicean* (1881), *Two on a Tower* (1882), *The Mayor of Casterbridge* (1886), *The Woodlanders* (1887), *Wessex Tales* (collected 1888), *A Group of Noble Dames* (1891), *Tess of the D'Urbervilles* (1891), *Life's Little Ironies* and *A Few Crusted Characters* (collected 1894), *Jude the Obscure* (1895), and *The Well-beloved* (1897). Much of Mr Hardy's earlier work was in poetry, but most of his verses he destroyed; and it was not till 1898 that a volume of *Wessex Poems* appeared. Mr Hardy has contributed largely to periodical literature, and two of his stories have been dramatised. Of his novels, some critics have preferred *The Return of the Native*, others *The Trumpet-major*; but *Tess of the D'Urbervilles* is for most people his most characteristic and, on the whole, his greatest work. It was not for nothing that in youth Mr Hardy, as architect's apprentice in church restoration, visited innumerable villages throughout Wessex; not for nothing did he elect to remain a Wessex man. If there be any tales that are racy of the soil, it is Mr Hardy's stories of Wessex life and manners. Quite exceptional is his command of rustic humour, of the Wessex dialect, and of pithy dialogue. But his chiefest characteristic is perhaps his determination at all risks to present in all its width and depth the tragedy of human life, perhaps to err on the side of regarding life as too terribly and inevitably sad and sombre. Our social system is very imperfect, even rotten; conventions and proprieties are hollow; cant and shams abound; our social code is cruel and cruelly unequal. Passion and the passions are the key of life and of literature, and freedom of speech must be maintained and exercised. Sincerity in art forbids the artist to call a spade anything but a spade, or to invent happy endings for too true stories. Even friendly critics reproach Mr Hardy with pessimism, sometimes to the verge of morbidness. But it may safely be said that if he is pessimist he is not cynical; enough there certainly is of satire and irony. In all his stories unity of plan is consistently kept in view, and incidents all work towards the inevitable conclusion. The nervous English style—appropriate rather than brilliant, natural rather than exquisite—is in just keeping with the austerity of the issues handled and the architectonic completeness of the presentment.

There are monographs on Mr Hardy and his art by Miss Macdonell (1894) and Mr Lionel Johnson (1894)—the latter with a full bibliography of Mr Hardy's publications.

Hardyng, or **Harding,** JOHN, a 15th century English rhyming chronicler, was born in 1378, and was brought up in the household of Harry Percy, the famous Hotspur, whom he saw fall on Shrewsbury field in 1402. Pardoned for his treason, he served under Sir Robert Umfraville, became constable of Warkworth Castle, fought at Agincourt, and served the crown in confidential and critical missions to Scotland. His chronicle, composed in limping stanzas, and treating the history of England from the earliest times down to the flight of Henry VI. into Scotland, he rewrote and presented to Edward IV. just after his accession. It is poor history and poorer poetry, but the account of the Agincourt campaign has the interest of the eye-witness. For his hostility to the Scots he had apparently good grounds in his own experience. Hardyng's *Chronicle* was continued by the printer Richard Grafton down to the thirty-fourth year of the reign of Henry VIII., but Grafton's work was little more than a recast of Hall. The best edition of Hardyng's *Chronicle* and its continuation is that by Sir Henry Ellis (1812).

Hare, a term including all members of the rodent family Leporidæ, with the exception of the rabbit. Its chief distinctive characters are as follows: four incisor teeth in the upper jaw (instead of two as in most Rodentia), two small square teeth standing immediately behind the well-known front teeth; five or six molars in the upper and five in the lower jaw, which are composed of two flat plates disposed transversely; lips thick, with a deep median incision and very mobile, with long bristles; eyes large; ears more or less long; head and body long and compressed; hind-legs long (except in Lagomys), five toes on the fore, four on the hind legs; tail short. The body is covered by a thick, almost woolly coat, which is in some demand for making hats. Two recent genera only are included, Lepus and Lagomys. The Common Hare (*Lepus timidus*) is about 27 inches in

The Common Hare (*Lepus timidus*).

length—of which only 3 inches belong to the tail—1 foot high, and weighs 13–20 lb. The fur consists of two kinds of hairs, one short, thick, and

woolly, the other longer and stouter. The colour, owing to the varying tints of these two sets of hairs, is a dull reddish-brown, paler on the sides and white below, which from its resemblance to the earth is admirably adapted to conceal the animal.

The hare is in the main of nocturnal habits, and passes the day sleeping in its 'form,' a slight depression among the grass and other herbage, sheltered from the sun in summer and the wind in winter. In the evening it creeps out to feed, nearly all vegetable substances being palatable to it; green vegetables and root-crops are, however, its special delicacies, though it will gnaw the bark off trees when hard pressed. In places where it is protected by game-laws it does great damage on account of its voracity and fertility.

In addition to its protective colouring, caution and speed are the hare's security. Crouched in its form, on any sign of danger it at once sits up on its haunches and looks around; its next action is to crouch down and try to conceal itself; should this fail and the enemy approach too near, it betakes itself to flight, in which its long hind-legs give it a great advantage in running either on a level or uphill; in descending it proceeds diagonally, otherwise its springs would overturn it. Its course is chosen with great cunning so as to place all possible obstacles in the way of its pursuer, and though it does not take naturally to water it has been known to swim a considerable distance when closely pressed. It has many enemies; nearly all beasts and birds of prey will attack it, not to mention man, whose pursuit is treated in special articles (see COURSING; also GAME LAWS).

The time of pairing is in February or March, and at this period the pugnacity, which is even more a characteristic of this cautious animal than its proverbial timidity, comes into evidence, for the males fight ferociously for the females. The period of gestation is thirty days; there are three to five young (known as 'leverets') in each litter, and four (rarely five) litters are produced yearly; the first in March, the last in August. The young can see when born, and are only indifferently tended by their mother for about a month.

The Common Hare is distributed over the greater part of Europe and a small portion of western Asia, as far north as Scotland, south Sweden, and Persia, and as far south as France and north Italy. Three different local varieties have been recognised: (1) the South European (*L. mediterraneus*, *L. meridionalis*), small, short, with looser hair of a reddish tinge; (2) the Mid-European (*L. timidus* s. str., *L. campicola*), stouter, with longer hair and brownish-gray; (3) the Eastern form (*L. caspicus*), very thick-haired, and gray or whitish-gray in colour.—The Irish Hare, formerly known as *L. hibernicus*, is not regarded as a distinct species by the best authorities, but as a variety of the Alpine hare.

The Alpine Hare (*L. variabilis*) is distinguished by its smaller size, the shortness of the ears, which are not so long as the head, the white tail about half the length of the head, and the form of the first upper molar. It occurs in the circumpolar regions as far south as 55° N. lat., and also in elevated positions in more temperate regions, such as the Alps, Pyrenees, and probably the Caucasus. As a British form it is confined to the north of Scotland and Cumberland. Three different varieties have been described: (1) the Polar, white both in summer and winter, with the exception of the tips of the ears; (2) alpine form or 'Blue Hare,' grayish-brown in summer; (3) temperate form, grayish-brown both summer and winter, but somewhat whitish in the latter season. The Irish hare is probably this form.

Two species of hare have been recorded from India and central Asia, and one from the Cape. The American continent yields some dozen different forms, only one of which, however, occurs in the southern portion. Among these are the Polar Hare (*L. glacialis*), the Northern Hare (*L. americanus*), and *L. aquaticus* and *L. palustris*, the Swamp and Marsh Hares; these last are excellent swimmers and divers.

Fossil hares have been found in the Pliocene formations of France, the Post-Pliocene of North America, and the caves of Brazil.

The Pikas belong to the genus Lagomys (sometimes made the type of a distinct family, Lagomyidæ), which is distinguished from Lepus by its short hind-legs, very short tail, and rounded ears, as well as by the presence of complete collar-bones.

The type species *L. alpinus* somewhat resembles a Guinea-pig in shape and size; the colour is reddish-yellow sprinkled with black above, redder on the sides and front of the neck, paler below. It continually emits a penetrating whistle, repeated two or three times in succession, which has been compared to the note of a woodpecker. It inhabits burrows in the ground which it excavates for itself, and in which it stores up food for the winter. Its habits are nocturnal. There are eleven different species, which extend from Kamchatka along the chain of mountains in the centre of Asia, just entering Europe in the neighbourhood of the Volga. In America they are confined to certain parts of the Rocky Mountains. See FURS; and *The Hare*, by Macpherson, Lascelles, &c. ('Fur and Feather' series, 1896).

Hare, JULIUS CHARLES, one of the chief early leaders of the Broad Church party, was born near Vicenza, in Italy, September 13, 1795. He spent part of his boyhood in Germany, and after his return was sent to the Charterhouse, from which in 1812 he passed to Trinity College, Cambridge. Here he was elected to a fellowship in 1818, and afterwards became classical lecturer. He tried the study of law, but soon abandoned it, took orders in 1826, and succeeded his uncle in the rich family living of Hurstmonceaux, Sussex, in 1832. He gathered round him a fine library of 12,000 volumes, and numbered among his friends Landor, Maurice, Bunsen, and others of the greatest spiritual teachers of his time. He had John Sterling as his curate (1834–35), and married in 1844 Esther Maurice, sister of Frederick Maurice. He became Archdeacon of Lewes in 1840, in 1853 chaplain to the Queen, and died January 23, 1855. His annual charges are among the most important sources for a study of the ecclesiastical controversies of his time. Another great service that he did was to awaken Englishmen to the fact that they had much to learn in theology from Germany. His style is cumbrous, and his books gain nothing from their orthographical peculiarities. Already in 1820 he had translated Fouqué's *Sintram*, when in 1827 he published anonymously *Guesses at Truth*, written in conjunction with his brother Augustus. His next work was the translation of Niebuhr's *History of Rome* (1828–32) in collaboration with Thirlwall, and his own *Vindication of Niebuhr's History* (1829). His most important contributions to theology are *The Victory of Faith* (1840) and *The Mission of the Comforter* (1846), two series of elaborate sermons preached at Cambridge. In 1848 he edited the *Remains of John Sterling*, with a life, a strong sense of the inadequacy of which inspired Carlyle's masterpiece. Other books are *Parish Sermons* (2 vols. 1841–49) and a *Vindication of Luther against his Recent English Assailants* (1854). See his nephew's *Memorials of a Quiet Life*.—His elder but less important brother, AUGUSTUS WILLIAM HARE, was born in 1792,

and educated at Winchester and New College, Oxford, where he became a Fellow in due course. He was appointed in 1829 to the retired living of Alton Barnes, in Wiltshire, married in 1829 the gifted Maria Leycester (1798–1870), and died prematurely at Rome in 1834. Besides his share in the *Guesses at Truth*, he left fifty-six sermons to be published in two volumes in 1837. Augustus John Cuthbert Hare, nephew of the two preceding, was born at Rome in 1834, and was educated at Harrow and at University College, Oxford. He has written a series of good descriptive books revealing fine artistic taste and wide knowledge of history and antiquities. Amongst these are *Walks in Rome* (1871), *Wanderings in Spain* (1873), *Days near Rome* (1875), *Cities of Northern and Central Italy* (1876), *Walks in London* (1878; new ed. 1894), *Cities of Southern Italy and Sicily* (1883), *Holland and Scandinavia* (1885), *Studies in Russia* (1885), *Paris* and *Days near Paris* (1887), *South Eastern France* and *South Western France* (1890), *Sussex* (1894), &c. Other works are his delightful biography of Maria Hare, *Memorials of a Quiet Life* (1872–76); the *Life and Letters of Baroness Bunsen* (1879), *Two Noble Lives* (1893), and *The Gurneys of Earlham* (1895). See his autobiography (1896).

Hare, Robert, scientist, was born in Philadelphia, 17th January 1781, and filled the chair of Chemistry in the University of Pennsylvania there from 1818 to 1847. He died 15th May 1858. In 1801 Hare described his discovery of the oxy-hydrogen blowpipe (see Blowpipe). In 1816 he invented the galvanic calorimotor. He also devised improved forms of the voltaic pile. In his later years he lectured on spiritualism and published *Spiritualism scientifically demonstrated* (New York, 1855).

Hare and Hounds. See Athletic Sports.

Harebell, or Bluebell (*Campanula rotundifolia*), the most common of the British species of Bellflower (see Campanulas), growing in dry and hilly pastures, on waysides, &c., is found in most parts of Europe. It is a perennial plant, with a slender stem 6 to 14 inches high, bearing a loose raceme of a few drooping flowers, on very slender stalks; the flowers, generally bright blue, but sometimes white, bell-shaped, and about half an inch long, appear in summer and autumn. The juice of the flowers yields a fine blue colour, and may be used as ink.

Harebell (*Campanula rotundifolia*): *a*, lower stem-leaves.

Hareld (*Harelda*), a genus of the duck family (Anatidæ, see Duck), having a short thick bill, and two feathers of the middle of the tail, in the males, greatly elongated. Two species are known; the best known, the Long-tailed Duck or Hareld (*H. glacialis*), inhabits the arctic regions both of the Old and New Worlds, its winter migrations in America extending as far south as the Carolinas.

Harelip is the name applied (from its resemblance to the lip of the hare) to a congenital notch or cleft in the upper human lip, due to imperfect union at an early stage of development of the processes whose formation and fusion separate the mouth from the cavity of the nose. The cleft is not in the middle line, however, as in the hare; but a little to one side (*single* harelip), or there are two clefts, one on each side (*double* harelip). This deformity, especially when double, is often associated with a similar defect in the roof of the mouth (cleft palate). The cause of these arrests of development is quite unknown. Harelip is not at all dangerous, but very unsightly. It can be remedied by a surgical operation, which most surgeons prefer to perform during infancy.

Harem (Arab. *El-Harim*, 'the inviolable') is that part of a polygamist's house which is set apart for the use of his wives and their attendants; it also denotes this collective body of women. In all Mohammedan countries it is customary for wealthy men to keep a harem; for, though four is the number of wives to which the faithful are restricted by the Koran, there is no limit to the number of concubines a man may have except his ability to maintain them. The mention of a harem naturally suggests to most people the female portion of the royal households of Turkey and Persia and Egypt. In the sultan's harem each wife—he alone may have seven—has a separate suite of apartments and a separate troop of female slaves to wait upon her and do her bidding. All the female slaves or odalisques throughout the harem are, however, at the disposal of their royal master. She who first gives birth to an heir, whether wife or slave, is instantly promoted to the rank of chief wife. The title sultana is borne, not by the sultan's wives, but by his mother, sisters, and daughters. The real ruler of the harem is the sultan's mother, but under her is the lady-superintendent of the harem, usually an old and trusted favourite of the sultan. The duties of guarding the harem or seraglio (Ital. from Latin *sera*, 'a bar;' cf. Turkish and Persian *serai* or *saray*), as it is sometimes called, are entrusted to a small army of eunuchs, the chief officer of whom generally enjoys considerable political influence. The inmates of the harem lead a very secluded life. They are not allowed to be seen by men, except their nearest relatives, as father and brother. Their principal occupations are needlework, spinning, and embroidery, which are relieved by the 'cult' of the toilette, and such amusements as dancing, singing, and games. On the death of the sultan those women who have borne daughters to him are at liberty to leave the harem and marry again; the mothers of princes are transferred to the 'old seraglio,' and kept there until they die. In the harems of the great men of Turkey and Egypt a good deal of modern European luxury has been introduced of late years, and the ladies now dress themselves in accordance with fashions derived from Paris or London.

The institution is not, however, confined to Mohammedan countries, but flourishes also, or did flourish, in some form or other, amongst the Jews, Babylonians, ancient Persians, Siamese, &c. In Bangkok, the capital of Siam, the harem of the king forms a walled city within the larger city, so extensive is it.

The holy cities of Mecca and Medina are together called the harems or the sacred places, and the sacred mosque at Mecca is designated the *mesjid el-harim* or 'the inviolable mosque.'

During the 18th and 19th centuries the interiors of oriental harems have been entered and the lives of their inmates studied by several European and American ladies, as those of Constantinople by Lady Mary Wortley Montagu in 1716; those of

Cairo and Damascus by Harriet Martineau in 1847; that of the Khedive at Cairo by two ladies of Mr W. H. Seward's American party in 1871; some in Turkey by another American lady, Mrs Caroline Paine; and the royal harem at Bangkok by yet another lady from the United States, Mrs Leonowens. For harems in India, see ZENANA.

Hare's-ear (*Bupleurum*), a genus of plants of the order Umbelliferæ, having compound umbels of yellow flowers, and generally simple leaves. The leaves of the most common British species, *B. rotundifolium*, are perfoliate. This plant, which grows in cornfields in the chalk districts, is the *Thorough-wax* of the old herbalists. The species of hare's-ear are numerous, and are natives of temperate climates in most parts of the world.

Harfleur (called in the middle ages *Hareflot*), a town in the French department of Seine-Inférieure, is situated on the estuary of the Seine, 4 miles E. of Havre. Formerly Harfleur was an important seaport and maritime fortress, but the rise of Havre, coupled with the sanding up of its harbour, led to its decay. Pop. 2317. It was taken after a six weeks' siege by the English under Henry V. in 1415, and during the next twenty-five years changed hands three times. It was pillaged by the Huguenots in 1562.

Hargraves, EDMUND HAMMOND, the discoverer of the goldfields of Australia, was born at Gosport, in England, in 1815. When eighteen years of age he settled in Australia. Attracted to California in 1849, he there tried his luck as a gold-digger, and whilst so engaged was greatly struck by the similarity in the geological formation of California and Australia, and suspected that gold would be found in the latter. On his return home he proved the correctness of his surmise by discovering gold on the western slopes of the Blue Hills in New South Wales in 1851. He was appointed commissioner of crown-lands, and received from the government of New South Wales a reward of £10,000. In 1855, one year after his return to England, he published *Australia and its Goldfields*. He died in October 1891.

Hargreaves, JAMES, the inventor of the spinning-jenny, used in the manufacture of cotton, was an illiterate weaver and carpenter of Standhill, near Blackburn, in Lancashire, where he was born. In 1760 he helped Robert Peel (the founder of that family) in the construction of a carding-machine; and half-a-dozen years later he invented the spinning-jenny, the idea of which is said to have been suggested to him by seeing a spinning-wheel, which one of his children had upset, continue to revolve horizontally, whilst the spindle revolved vertically. But his fellow-spinners, imbued with strong prejudices against machinery, broke into his house and destroyed his frame. He then removed to Nottingham (1767), where he erected a spinning-mill. Three years later he took out a patent for his invention; but, as it was proved that he had sold some of his machines before the patent was obtained, it was thereby declared to have been invalidated. Hargreaves continued to carry on business as a yarn manufacturer till his death on 22d April 1778, when his share in the mill was bought by his partner for £400. See Francis Espinasse's *Lancashire Worthies* (1874).

Haricot. See BEAN.

Hari-kari (rather *hara-kiri*, 'belly-cut,' also called 'happy despatch'), a term applied to the curious Japanese system of official suicide, obsolete since 1868 (see JAPAN). The Japanese estimated the number of such suicides at 500 per annum. All military men, and persons holding civil offices under the government, were held bound, when they had committed an offence, to disembowel themselves. This they performed in a solemn and dignified manner, in presence of officials and other witnesses, by one or two gashes with a short sharp sword or dagger 9½ inches long. Personal honour having been saved by the self-inflicted wound, the execution was completed by a superior executioner (or rather the victim's second, often a kinsman or friend of gentleman's rank), who gave the *coup de grâce* by beheading the victim with one swinging blow from a long sword. Japanese gentlemen were trained to regard the hara-kiri as an honourable expiation of crime or blotting out of disgrace. See articles by an eye-witness in *Cornhill* (1869).

Häring, GEORG WILHELM HEINRICH, better known under the name of WILIBALD ALEXIS, a German novelist, was born at Breslau, 23d June 1797. He at first studied law at Berlin and Breslau, but abandoned this pursuit for a literary career. His first success as a writer was the historical romance *Walladmor* (1823–24), published as a work by Sir Walter Scott, a fraud that found belief and led to the book being translated into several languages (into English, very freely, by De Quincey, 1824). This was followed by *Die Geächteten* (1825) and *Schloss Avalon* (1827). Häring's subsequent historical romances, the clever character-drawing, historical verisimilitude, and vigorous description of which entitle them to a high rank, are *Cabanis* (6 vols. 1832), *Roland von Berlin* (3 vols. 1840), *Der falsche Woldemar* (3 vols. 1842), *Hans Jürgen und Hans Jochem* (2 vols. 1846), *Der Werwolf* (3 vols. 1848), *Ruhe ist die erste Bürgerpflicht* (5 vols. 1854), *Isegrimm* (3 vols. 1854), and *Dorothe* (3 vols. 1856). Besides these, he wrote books of travel, sketches, dramas, and other works. His *Gesammelte Werke* were published at Berlin in 20 vols. in 1874, the historical romances as *Vaterländische Romane* in 8 vols. in 1884. He died 16th December 1871.

Harington. See HARRINGTON.

Hariri. ABU MOHAMMED AL KASIM IBN ALI, surnamed AL-HARIRI ('the Silk-merchant'), an Arabic writer, was born at Basra, on the Tigris, in 446 A.H. (1054 A.D.), spent his life in study and devotion to literary work, and died at Basra about 1121. He wrote valuable works on Arabic grammar, as *Molhat el Irab*, a work on syntax, and *Durrat el-Ghawwas*, on common faults in current language. But the most famous of his writings, indeed one of the most famous compositions of all times and countries, is his *Makamat* (Literary Gatherings). This is a collection of rhymed tales, the central character in which is a certain Abu Seid from Seruj, a witty, clever, amiable rogue, well read in sacred and profane lore, but cunning and unscrupulous, who turns up under all possible disguises and in all possible places. The brilliancy of imagination and wit displayed in these adventures, their striking changes, and dramatic situations, have hardly ever been equalled; but more wonderful still is the poet's power of language. The whole force of the proverbial fullness of expression, spirit, elegance, and grandeur of the Arabic idiom has been brought to bear on the subject. Indeed, as far as language is concerned, the *Makamat* is looked upon in the East as the highest source of authority next to the Koran. The book has been translated, either entirely or partially, into nearly every Eastern and European tongue, and has been the prototype of innumerable imitations, the most successful being one in Hebrew, *Machberoth Ithiel*, by Yehudah ben Shelomoh al-Kharizi. The best edition of the *Makamat* is that by Silvestre de Sacy, which appeared in Paris, 1822 (re-edited 1847–53). Of translations, the palm is due to Rückert, who

has completely reproduced the spirit and form of the work in his *Verwandlungen des Abu Seid von Serug*, first published in 1826. English translations (partial) have been made by Preston (1850) and by Chenery (1867).

Hari-Rud, or HERI RUD, a river of Asia, which rises in the Hindu Kush about 150 miles W. from Kabul, pursues a western course through Afghanistan for nearly 250 miles; then, bending suddenly to the northward, it forms the boundary between Persia and Turkestan, and, after a further course of about 250 miles, loses itself in several arms in the Tekke Turkoman oasis.

Harivansa, a Sanskrit epos, which professes to be part of the Mahabharata, but may be more properly classed with the Puranas (q.v.).

Harlamoff, ALEXIS, a Russian artist, born at Saratoff in 1844, studied at St Petersburg Academy of Fine Arts, gained several medals, became a member of the Academy in 1869, and soon afterwards settled in Paris. A regular contributor to the Salon, his portraits and pictures of children and young girls, executed with feeling and painstaking care, have rendered him famous. See R. Walker's article in *Good Words* (1889).

Harlaw, 18 miles NW. of Aberdeen, the site of a battle fought on 24th July 1411, between the Highlanders led by Donald, Lord of the Isles, and the Lowlanders of Mar, Garioch, Buchan, Angus, and Mearns, under Alexander Stewart, Earl of Mar. The battle was long and bloody, but the Highlanders were at last driven back, leaving more than 900 dead upon the field. For long after 'the red Harlaw' was a favourite theme of legend and song.

Harlech, an ancient town of Merionethshire, North Wales, stands on the coast, 10 miles N. of Barmouth. On a steep hill overlooking the sea is its massive castle, which held out for the Lancastrians in the Wars of the Roses, and later for Charles I. The 'March of the Men of Harlech' commemorates its capture by the Yorkists in 1468. For the Harlech series, see CAMBRIAN SYSTEM.

Harlequin. See PANTOMIME. The etymology of the word is curious. The Fr. is *arlequin*, from which apparently is derived the Ital. *arlecchino*. The Old Fr. phrase was *le maisnie hierlekin* (Low Lat. *harlequini familiares*), 'a troop of demons that haunted lonely places.' This Skeat derives from Old Fries. *helle cyn*, Icel. *helgar kyn*, i.e. the kindred of hell, host of hell, troop of demons. The change from *hellequin* to *harlequin* was due to a mistaken analogy with *Charles Quint*. See MAX MÜLLER'S *Lectures*, ii. p. 581.

Harlequin Duck (*Anas* [or *Clangula*] *histrionica*), a species of Garrot which receives its name from its variegated markings, white, gray, black, and brown. It inhabits the seashore and its inlets and river mouths, being seldom seen inland. It is found in Kamchatka and Greenland, on the shores of the Caspian Sea, Sea of Aral, and Lake Baikal. In America it is found in Labrador, Hudson Bay, Newfoundland, and Bay of Fundy, and advances in winter southwards to the United States. Its whole length is about 17 inches. See WILD-DUCK.

Harless, GOTTLOB CHRISTOPH ADOLF VON, a German Lutheran theologian, was born at Nuremberg in 1806, and was professor of Theology at Erlangen from 1836, and at Leipzig from 1845. In 1850 he became chief court preacher at Dresden, and exercised great influence on ecclesiastical affairs in Saxony. In 1852 he was appointed president of the Protestant consistory at Munich, and succeeded in making the Lutheran Church in Bavaria strongly orthodox. He died 5th September 1879. His most important works were his *Theologische Encyklopadie und Methodologie* (1837) and *Die christliche Ethik* (1842; Eng. trans. 1868). His autobiography appeared as *Bruchstücke aus dem Leben eines Sudddeutschen Theologen* (1873-75).

Harley, ROBERT, EARL OF OXFORD AND MORTIMER, the son of Sir Edward Harley, an active partisan of the Parliament during the civil wars, was born in London, 5th December 1661. The politics of the family were Whig, and as such Robert Harley entered parliament for the Cornish borough of Tregony. But at the end of his first parliament he was elected for New Radnor, and this constituency he continued to represent until 1711. He soon acquired a great reputation for his knowledge of parliamentary law and practice, and in the parliament which met under the chieftainship of Rochester and Godolphin, in February 1701, he was elected speaker. This post he retained until 1705, though in April 1704 he became also Secretary of State. But shortly after this time Harley began to influence the queen's mind against the party of Marlborough and Godolphin; for, apparently from motives of personal ambition, he now began to intrigue with and for the Tories, and he found a most useful ally in his cousin, Abigail Hill (Mrs Masham). Godolphin failed not to detect what was going forward, and in February 1708 the conviction of Harley's secretary for treasonable correspondence with France caused his master to resign office. The discarded minister then set to work, aided by his cousin, to undermine the power of the Whigs, and in August 1710 Godolphin was dismissed, Harley being appointed Chancellor of the Exchequer and made head of the government. In 1711 occurred an event which raised Harley to the acme of popularity. A French priest and spy, who assumed the title of Marquis de Guiscard, being brought before the council on the 8th of March on the charge of treasonable correspondence with France, suddenly stabbed Harley in the breast with a penknife. His life was said to have been in danger, but he recovered, and was created Earl of Oxford and Mortimer, made a knight of the Garter, and in May appointed Lord High Treasurer of Great Britain. He was the last to bear this title; henceforth the chief adviser of the sovereign was known as the first minister to the crown, or the prime-minister. The principal act of Harley's administration was the treaty of Utrecht, the opposition of the Whig majority in the Upper House being overcome by the creation of twelve new peers. But Oxford's popularity was already on the wane; the friendship between him and Bolingbroke had degenerated into bitter jealousy, and was fast turning to hatred, and Mrs Masham sided with Bolingbroke. Moreover, Oxford estranged the Jacobites by his irresolution and want of a decided policy. On 27th July 1714 he was dismissed from office, his successor being Bolingbroke. Five days later, however, the queen died, and George I. was proclaimed king. In July of the following year Oxford was impeached and sent to the Tower, but after two years' imprisonment was acquitted by the Peers, and released. He spent the remainder of his life in retirement, the friend of scholars and men of letters, especially of Swift, and the founder of the Harleian collection of books and MSS. in the British Museum (q.v.). The Harleian Society, named from him, was founded in 1869 for the publication of heraldic visitations, &c. He died May 21, 1724. Harley was not a great statesman; the fault that marred his career was indecision of purpose, a desire to stand well with all parties. He followed no decided policy, but intrigued all round, not only with Whigs and with Tories, but also with the enemies of his country. Consequently he was distrusted by all parties and loved by none. See the *Harley Papers* (1897).

Harlingen (Frisian *Harns*), a seaport of the Netherlands, in the province of Friesland, on the Zuider Zee, 14 miles W. by S. from Leeuwarden. It has a good harbour (1875), protected from the sea by dykes. The manufacture of linen sacks and machines and shipbuilding are the chief industries. Butter and cattle are exported to England. Pop. 10,274.

Harmalin is a vegetable base, and *Harmin* another, both of which occur in the husk of the seeds of *Peganum harmala*, or Syrian rue, a zygophyllaceous, shrubby plant that grows abundantly in the steppes of southern Russia. The seeds have been used in dyeing silk, to which they impart various shades of red.

Harmattan, a hot desiccating wind, prevalent on the Guinea coast during December, January, and February, which blows from the interior to the Atlantic Ocean. It is generally preceded by clouds of extremely fine sand, called 'smokes' or 'fog,' which penetrates everywhere and covers everything. It has a hurtful effect on vegetation, and on the human body, drying up the eyes, nostrils, and mouth, and even causing the skin to peel off. The negroes protect themselves against it by rubbing the body with fat or grease. It has, however, the good effect of checking epidemics, and curing dysentery, fevers, and cutaneous diseases. The harmattan is similar to the Sirocco (q.v.) of Italy.

Harmodius and **Aristogeiton,** two Athenians strongly attached to each other, who in 514 B.C. murdered Hipparchus, the younger brother of the 'tyrant' Hippias, partly on account of an insult offered by him to the sister of Harmodius, and partly with a view to the overthrow of the Pisistratidæ. They meant to kill Hippias also, but Harmodius was cut down by the bodyguard of Hipparchus, whilst Aristogeiton fled, but was afterwards taken and executed. Subsequently they came to be regarded as patriotic martyrs, and received divine honours from the Athenians, and had statues raised to their memory. A beautiful drinking-song by Callistratus celebrates their deed.

Harmonica, a musical instrument, invented in 1760 by Benjamin Franklin, the sounds of which were produced from bell-shaped glasses, placed on a framework that revolved on its centre, while the rims were touched by the moistened finger. An instrument of the kind was used at Nuremberg in the 17th century. In 1746 the great composer Gluck, and in 1750 an Irishman named Puckeridge, played in London airs on a row of glasses, tuned by putting water into each. When Franklin finished his invention, in which the pitch was regulated by the size of the glasses alone, he found an excellent performer in Miss Marianne Davies, to whom he made a present of his harmonica, and who during 1762–73 performed on it with great effect in London, Paris, Vienna, Milan, Naples, &c. This fascinating instrument found many admirers, but none of them ever succeeded in improving it. The production of the sound by the points of the fingers caused such an effect on the nerves of the performer as in some instances to induce fainting fits. All attempts to make the harmonica easier for amateurs through means of keys ended in failure, since no substance was found to act as a substitute for the human finger. The harmonica gave rise to a host of similar instruments by Chladni, Kaufmann, and others, which were not particularly successful. Other instruments of no merit or importance took the same or a similar name, but had not the most remote resemblance to the original—e.g. steel pegs or strings being substituted for the glasses (see HARMONICON). The original harmonica, for which Mozart and Beethoven composed, was the instrument popularly known as musical-glasses. See Pohl, *Zur Geschichte der Glasharmonica* (1862).

Harmonica, CHEMICAL. This term is applied to the musical note which is evolved when a long dry tube, open at both ends, is held over a jet of burning hydrogen. A rapid current is produced through the tube, which occasions a flickering, and is attended by a series of small explosions, that succeed each other so rapidly and at such regular intervals as to give rise to a musical note, whose pitch and quality vary with the length, thickness, and diameter of the tube. See FLAME.

Harmonic Engine, an invention of Edison's, in which the energy of an electric current is used, by means of two small electromagnets, to keep up the vibrations of a large and heavily weighted tuning-fork. The arms of the tuning-fork are connected with two pistons which work a miniature pump, and this may compress air, which, in its turn, can drive sewing-machines or do other light work.

Harmonicon, a musical instrument consisting of glass or metal plates supported on strings at points about one-fourth of the length from the free ends. The plates are struck by soft hammers and enter into transversal vibrations, the frequency of which varies directly as the thickness, inversely as the square of the length, directly as the square root of the elasticity of the vibrating material, and inversely as the square root of its density. The points of support become nodal points.

Harmonic Proportion. Three numbers are said to be in harmonic proportion when the first is to the third as the difference between the first and second is to the difference between the second and third; otherwise, harmonic proportion is that which subsists between the reciprocals of numbers which are in arithmetical proportion. Thus, 3, 5, 7, &c., being in arithmetical proportion, $\frac{1}{3}$, $\frac{1}{5}$, $\frac{1}{7}$, &c., are in harmonic proportion. In geometry, a line

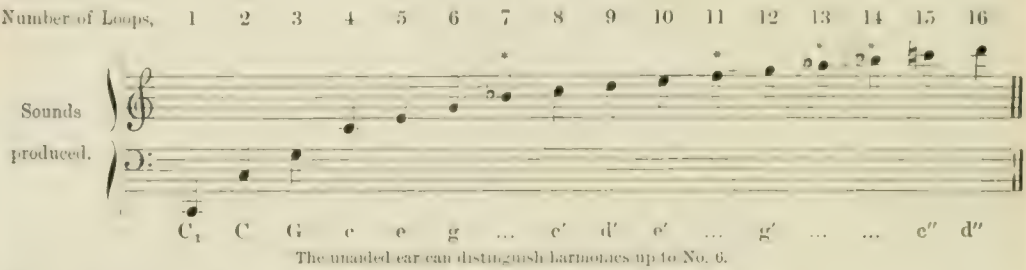
A C B D

AB is said to be harmonically divided when two points are taken, one in the line and the other in the line produced, as C and D, such that AC : CB : : AD : DB. When the line is thus divided, AD, CD, and BD are in harmonic proportion. A harmonic progression is a series of numbers in harmonic proportion, as the series formed by the reciprocals of numbers forming an arithmetical series.

Harmonics. Every musical sound, although to the untrained ear it appears to be single, will, on close observation, be perceived to consist of a principal or fundamental tone accompanied by higher tones or harmonics which blend and generally harmonise with it. The existence of such harmonics (or partial tones) may be perceived on loudly sounding a low note on a pianoforte with the loud pedal held down: as the sound dies away the harmonics become more and more prominently audible, especially when they are singly listened for one after the other; and the more tinkling the quality of tone of the instrument the more readily they are heard. In fact, in a tinkling pianoforte they are at all times louder than the fundamental tone, though they are masked by it, as all high tones appear to the ear to be masked by lower tones; and the tinkling quality is due to their presence. The peculiar recognisable character of all sounds—different voices, pianoforte, organ, violin, &c.—is due to the presence of harmonics, each with its own intensity; and by sounding along with a simple fundamental sound a number of harmonic tones, each with varying degrees of loudness, an

endless range of quality may be conferred upon the fundamental tone.

For demonstration of harmonics in sounds of all kinds a series of resonators is necessary. When a tuning-fork is vibrated near a hollow vessel of suitable capacity (say a lamp-chimney sunk in water to an adjusted depth), the air within the hollow vessel vibrates in unison with the fork and emits a loud sound; similarly, when the capacity of such a resonator corresponds to the pitch of a harmonic tone present in a given sound, the resonator sounds out that harmonic. By a series of such observations all the harmonics can thus be severally recognised. The physical basis of harmonic tones is the fact that no vibration of an elastic body is ever accomplished without a more or less well-marked division of the vibrating body into segments which vibrate independently and simultaneously. To realise this, take a long string stretched between two points; set it in vibration by means of a violin-bow; the cord will appear to vibrate as a whole. Now, by means of the finger-nail or of a stretched thread lightly pressed upon it at the exact mid-point, 'stop' the mid-point and again bow; the string will appear to vibrate in two independent halves or loops, with a node or point of rest between them; the vibrations will be twice as frequent as at first, and the sound produced will be the octave of that originally heard. Again, stop a point one-third of the length from either end and again set in vibration; two nodes and three loops will be formed; the vibrations will be three times as frequent, and the sound will be the twelfth above the original fundamental. In the same way, any point cutting off one aliquot part of the string may be stopped; the string will spontaneously form the corresponding number of nodes and loops when set, in any fashion, into vibration. If we suppose the original sound to have been C_1 on the second ledger line below the bass staff, the various sounds produced by treating the string in this way will respectively be:



The unaided ear can distinguish harmonics up to No. 6.

The notes marked with asterisks are not notes of the natural scale; 7 and 14 are a flat B♭ often to be heard in the sound of chime-bells; 11 is nearer F♯ than F♮; 13 is nearer to A than it is to G♯. Now, in a vibrating string all these vibrations co-exist; to what degree any one shall be present depends on the way in which, or the point at which, the string is bowed or struck or plucked; and the quality of the resultant note varies accordingly. From the harmonics the true ratios of the members of the diatonic scale may be found—e.g. *b'* has a frequency of vibration 15 times as great as that of C_1; whence B_1 has a frequency $\frac{15}{8}$ times as great; and so for the rest, as follows:

Notes of the scale of C	C	D	E	F	G	A	B	C
Notes of any diatonic scale in general	d	r	m	f	s	l	t	d'
Ratios	1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2

For the modification in these ratios introduced by the system of temperament, see TEMPERAMENT. The standard work on Harmonics is Helmholtz's *Sensations of Tone* (trans. by Mr Ellis; 2d ed. 1885).

Harmonists. See RAPP.
